His statements are quite true, but the truth is put forth in such a way as to give an impression quite different to what should be conveyed. Dr. MacNalty's "eulogy" of pneumothorax does not inspire, and the results of pneumothorax treatment *are* inspiring. Dr. J. Gravesen (medical superintendent, Vejlefor Sanatorium, Denmark) stated at the annual meeting of the British Medical Association at Portsmouth Tuberculosis Section,[1] that "A comprehensive view of these 211 third-stage cases (2 to 12 years after discharge) shows a lasting positive result of the pneumothorax in 38 per cent. of all cases in which a pneumothorax of any noteworthy extent could be established." Further, that when there were no adhesions, 70·2 per cent. were able to work.

[3] Jour. of Amer. Med. Assoc., 1907, xlix., 1067.

[1] See THE LANCET, 1923, ii., 512.

Now look at Gravesen's statistics for thoracoplasty. Out of 105 patients 9 died from the operation; "43 were relatively cured or much improved, 21 improved." Of 69 patients discharged from two to seven years previously, 31, or 44·9 per cent., were fit to work. This, in truth, is a minority, but surely, considering what would have been the fate of these people, who were all advanced cases, this success deserves more "eulogy." Nor are Gravesen's figures exceptional; Bull's results are very similar, and my own experience—on a much smaller scale—has been equally happy.

I am, Sir, yours faithfully,

H. MORRISTON DAVIES,
Medical Supt., Vale of Clwyd Sanatorium.

Ruthin, North Wales, Jan. 28th, 1924.

KETOSIS IN CASUALTY PRACTICE.

To the Editor of THE LANCET.

SIR,—Without wishing to quibble with Dr. O. W. Roberts over terms of nomenclature, I think that a distinction ought to be made between cases of ketosis and those who merely exhibit ketonuria. The former condition is somewhat severe and comparatively rare, whereas the latter, in children, is a common accompaniment of many diverse conditions. No one has yet satisfactorily explained the mechanism of production of ketone bodies in the urine which can occur after anæsthesia, in starvation, in toxæmias and infections, and in certain metabolic explosions. Can any single theory cover all this ground? A comparison of results is therefore of interest and may stimulate inquiry into the ætiology of ketonuria; and I ask you to publish my clinical findings with that end in view.

I examined the urine of 316 in- and out-patients of the Bristol Children's Hospital, and as a control the urine of 112 normal school-children.

Of the 316 cases tested 116, or 36·7 per cent., showed ketonuria.
Of this 36·7 per cent. only 3·0 per cent. were cases of acetone body acidosis or ketosis.
The average age of cases tested was 6·1 years.
The average age of cases of ketonuria was 4·8 years.
Of the cases of ketonuria surgical cases gave 22·8 per cent., medical cases gave 49·2 per cent.; out-patient (total cases before operation) 28·0 per cent.
Of the medical cases 54·3 per cent. occurred in diseases of the respiratory tract; 23·2 per cent. occurred in diseases of the gastro-intestinal tract; 22·5 per cent. occurred in miscellaneous diseases.
The average duration of ketonuria was 2·6 days. There was pyrexia in 78 per cent. of all cases.
After general anæsthesia ketonuria occurred in 100 per cent. of cases.
After 24 hours complete starvation ketonuria occurred in 100 per cent. of cases.
The urine of 112 normal school-children (average age 10·7 years) was tested for acetone bodies. Number of positives, nil.

My findings are in close agreement with those of Dr. Roberts, especially with regard to the irritation of mucous membranes, and the higher incidence in the respiratory diseases was contrary to my expectations. There is undoubtedly some connexion between the catarrhal diathesis or hypersecretion of mucus, so liable to occur in childhood, and the onset of ketonuria; and this view is upheld by the fact that 28 per cent. of children with unhealthy tonsils or adenoids, who were presumably swallowing toxic mucus, were walking about all unknown with varying amounts of ketone bodies in their urine. The lethargy and somnolence of such cases may in part be explained by the action of ketone bodies on the central nervous system. And in addition the coexistence of pyrexia in 78 per cent. of all cases tested would rather tend to show that the outpouring of protective mucus or the stimulation of the anti-body mechanism has something to do with the appearance of ketonuria.

The efficacy of the treatment of ketonuria by sodium bicarbonate is probably due to the fact that that drug not only checks the secretion of mucus, but is a solvent of that already secreted. In passing I should like to repeat my statement which has already been published,[1] that ketonuria is met with in such metabolic upsets as asthma, eczema, migraine, eclampsia, and certain cases of epilepsy.

I am, Sir, yours faithfully,

Wellington, Salop, Jan. 28th, 1924. A. D. SYMONS.

THE HARD CASE OF AN UNREGISTERED DENTIST.

To the Editor of THE LANCET.

SIR,—May I ask you to insert my appeal in your estimable journal, so that I may state my case to all medical men, inasmuch as I have been deprived of my means of existence as the result of the new Dental Act?

I have lived in London since 1899 and have been practising as a dentist until 1917, and been respected and appreciated by my patients. I often gave free attendances for an hour or two in the morning to the poor who could not spare time to go to hospitals, and have many times made whole sets of dentures for some poor patients free of charge. During the war until 1917 I gave my services free to soldiers. Then I offered my services to the Government and was refused because I was too old, but as I wanted to do my bit in the war I went to Russia, and entered an army hospital as dentist in 1917, when Kerensky was in power.

Three months afterwards the Soviet came into power, and I was then compelled to serve in the Soviet Army as a dentist, where I went through such hardships and danger as I shall never forget. May I ask your indulgence to describe one incident? In 1919 our hospitals 41 and 48 received orders to evacuate. We were stationed in Orel and were expecting the enemy at any moment. We started to evacuate and had arrived near the town of Kaluga. There the train stopped in the middle of a field on account of the scarcity of locomotives, which were continually returning to bring up other carriages, and our echelon with the two hospitals and the medical staff was standing in the field nearly a month. At the beginning we received ¾ lb. bread per day; a week later we received ½ lb. per day; then we could not get any at all, and all our medical staff went rushing about the cropped fields looking for potatoes and white beetroot. We found very few, however, because the peasants had cleared everything away, having very little for themselves. In that year we could not manage to buy a pound of bread in the villages, so we tried to bake the beetroot, but it was bitter. We had to go a mile for water and carry it to our echelon. We had no tea or sugar, even of salt we only had ¼ lb. per month, and we all slept on bare dirty floors in the luggage wagons. That took place in the middle of October, 1919; it was already cold for the time of year, and snow had fallen. We had only summer clothing, and had to be out amongst all kinds of diseases and dying soldiers. Doctors and their assistants died, for typhus fever and many other diseases were raging, and although not ill myself, my sufferings were necessarily great until I was released from service. I arrived in London with great difficulty in every way and found the place where I now live. I sold everything left to me and I built up a practice, once more getting my old connexion back again.

Now I cannot be registered because I was not in practice in the United Kingdom up till 1921; although I have never committed any offence or had any claims from anybody during my whole life, and am now 70 years of age, yet I am not allowed to earn my living. Where is the humanity in making such a law? Skill is not considered at all. I am sure I am as well up in my profession as others. Why should I be deprived of my living? If I had any other means of making a livelihood I would turn to it. For this reason I appeal to all to have sympathy with me. Please write to the Dental Board to put my name on the Dental Register, so that I may continue to earn my living during the short time which remains to me.

I am, Sir, yours faithfully,

167, City-road, E.C., Jan. 24th, 1924. M. KAMM.

*** This is a very hard case. The Registration Committee has, however, been advised legally that it has no power to register the names of those who have not complied with the statutory conditions. Seeing how Mr. Kamm's default occurred we regret the impotence of the Registration Committee.—ED. L.

Medical News.

UNIVERSITY OF OXFORD: DEGREE DAYS.—Congregations will be held for the purpose of granting Graces and conferring Degrees in the present term on the following days, at 2.30 P.M.: Feb. 16th and March 6th and 29th.

ROYAL INSTITUTION OF GREAT BRITAIN.—On Feb. 5th, at 5.15 P.M., Prof. Arthur Dendy, F.R.S., will give his second lecture on What is Heredity? On Feb. 7th, at 5.15 P.M., Sir William Bragg, F.R.S., will give his first lecture on Crystalline Structure of Organic Substances.

RONTGEN SOCIETY.—A general meeting will be held on Feb. 5th, at 8.15 P.M., in the Institution of Electrical Engineers, Savoy-place, Victoria Embankment, London, W.C. A paper on the Recording of Action Currents in Nerve, with special reference to the use of the Cathode Ray Oscillograph will be read by Prof. H. S. Gasser. The Silvanus Thompson memorial lecture will be delivered by Prof. C. G. Barkla, F.R.S., on April 1st.

Mr. John Wheatley, Minister of Health, has appointed Mr. Douglas Veale, of the Ministry of Health, to be his private secretary, and Mr. A. N. Rucker to be his assistant private secretary.—Mr. Arthur Greenwood, M.P., Parliamentary Secretary of the Ministry of Health, has appointed Mr. H. H. George, M.C., to be his private secretary.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The programme for the month of February includes various special courses as well as a two weeks' intensive course from Feb. 4th to 16th at the North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham). The programme will cover the whole day and will include all the general and special departments of the hospital, in addition to a special lecture by a member of the staff at 4.30 P.M. The special Combined Course on Children's Diseases will embrace lectures and clinical demonstrations on medical and surgical diseases of children (including special departments), and there will be two sessions daily from Feb. 4th to the 29th. The following hospitals will participate: Paddington Green Children's Hospital, Royal Waterloo Hospital for Children and Women, Victoria Hospital for Children, and the "Children's Clinic," Western General Dispensary. A further course in venereal diseases will be given at the London Lock Hospitals from Feb. 4th to 29th. The course will include clinical work daily in the wards and out-patient departments at both hospitals with a special lecture by a member of the staff each day. From Feb. 5th to 28th special clinical demonstrations will be given at the London School of Tropical Medicine by Dr. G. Low and Dr. P. Manson-Bahr on Tuesdays and Thursdays, at 2 P.M. The subjects considered will be the more important diseases of tropical countries, illustrated by cases in hospital.

HOUSING IN DUBLIN.—It is just ten years, our Correspondent writes, since a departmental committee of the Local Government Board of Ireland reported on the housing conditions of Dublin. At that time the committee found that one-fourth of the tenement houses of the city were "unfit for human habitation and incapable of being rendered fit for human habitation." At the same time one-fifth of the population were living in one-roomed tenements. Since then there has been no building in Dublin, dilapidation has gone on, and it is likely that control by the sanitary authority has not been more effective. That conditions have not improved is made plain by the medical officer of health for Dublin, Dr. M. J. Russell, in an interview recently given to the press. Owing to the shortage of houses, he says, families are living in houses in which normally animals would not be permitted to live. The overcrowding increases the spread of tuberculosis and persons leaving sanatoriums quickly relapse on returning to their overcrowded dwellings. The infantile mortality is also increased by the housing conditions. Dr. Russell's description of the sanitary accommodation is identical with that given by the committee ten years ago. The closets of the tenement houses are dirty, and there is no attempt at separate accommodation for the sexes. The proportion of the population living in one-roomed tenements has increased from one-fifth to one-third. As most of the tenements in Dublin are in old houses originally intended for one family, each room now housing one or more families, the condition of the woodwork of the floors is beyond description. "One would need," says Dr. Russell, "to see the floors of one of these rooms taken up to fully realise what a fetid atmosphere must constantly emanate from underneath, and there is nothing so injurious to the health of young children." The corporation cannot venture to close even the worst houses since no other roofs would be available to shelter those dispossessed.

SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH.—This Institute has benefited by donations amounting to £600 made to its research endowment fund. Of this amount £500 has been donated by the British South African Explosives Co., one of the constituent companies of the Nobel industries, and £100 by Sir Harry and Lady McGowan. Sir Harry McGowan is the chairman of the Nobel industries.

UNIVERSITY OF MANCHESTER: THOMAS GRAHAM COLLOID RESEARCH LABORATORY.—Mr. W. B. Hardy, secretary of the Royal Society, opened this laboratory on Jan. 23rd. The foundation of the laboratory, which is the first of its kind, is mainly due to the efforts of a number of business firms which have recognised the importance, scientific and industrial, of this complex branch of physico-chemical investigation. The laboratory has been named after Thomas Graham, Professor at University College, London, and Master of the Mint, who was the founder of the study of the colloidal state of matter. Mr. D. C. Henry will be in charge of the new laboratory.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee 25 cases were considered and £299 voted to 23 applicants. The following is a summary of the new cases relieved:—

Widow, aged 67, of F.R.F.P.S. Glasg. who practised in Northamptonshire and died in 1906. Applicant has six children; the married daughters are unable to give monetary assistance but send clothes occasionally. The eldest son, a doctor, has largely supported his mother but is now only able to take locums and has five children of his own; he is only able to allow the applicant 5*s*. per week. The second son allows a similar amount. The applicant has had posts as housekeeper, but owing to her age and ill-health she is now unable to do the work. Voted £18 in 12 instalments.

Widow, aged 80, of M.R.C.S. Eng. who practised in Kent and died in 1881. Applicant mortgaged her property to start her son in business, but he died of consumption in 1915 before he could repay the loan. Then owing to the war she was unable to pay the interest and the mortgagees foreclosed, leaving her penniless. One married daughter has six children and is in reduced circumstances but allows her mother 10*s*. a week, the other daughter is a widow living on a small income and allows 35*s*. a week towards the expense of the applicant's board and necessary attendance owing to her advanced age. This second daughter asks the Fund to help as the allowance she makes is more than she can afford. Voted £26 in 12 instalments.

Daughter, aged 60, of M.R.C.S. Eng. who practised in France and died in 1884. The applicant has a superintendent's post at a G.F.S. Hostel at £50 per annum, but is much overworked and is in danger of breaking down. Voted £10.

Widow, aged 57, of L.R.C.P. Edin. who practised in Sheffield and died in 1911. This lady is in very bad health and has only received £4 10*s*. during the last 12 months by daily catering. This case was brought to the notice of the Fund by the C.O.S., who have been giving the applicant some help to pay her rent, which amounts to 7*s*. 6*d*. per week. Voted £10, and the C.O.S. have been asked to administer the grant.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

ABERDEEN: JOINT HOSPITAL SCHEME.—An address on the joint hospital scheme was given by Dr. David Lawson, of Banchory, at a meeting of the Aberdeen Rotary Club on Jan. 25th. The scheme had been under discussion for some considerable time—a joint hospital comprising the accommodation of the Aberdeen Royal Infirmary, the Sick Children's Hospital, beds for tuberculosis patients, together with a pathology department and university class-rooms for students, was obviously greatly to the advantage of all concerned over the isolated buildings at present occupied. The site chosen was at Forresterhill, Burnside; 111 acres had been purchased for £35,000. Dr. Lawson went on to say that there was the possibility that a trust would present the site to the infirmary. In discussing the existing arrangements, he pointed out the total inadequacy of beds, not only at the Sick Children's Hospital, but also at the Aberdeen Royal Infirmary. 200 beds were urgently required for the Sick Children's Hospital; tuberculosis patients required 150 beds. The size of the waiting list of patients desiring admission to the infirmary in itself was a clear indication of the inadequacy of the present accommodation. Many surgical beds were occupied by emergency cases. One surgeon stated that 15 of his 22 beds were filled by such cases. Waiting lists steadily grew, and patients had to wait months for admission. This greatly militated against successful early treatment, and early treatment was essential for first-class surgical results. The new scheme provided for 500 to 600 beds for the infirmary. Class-rooms and a hostel were to be provided for students engaged in clinical studies. Prof. Ashley W. MacIntosh commented on the great difficulty in carrying out certain methods of treatment under the existing régime, instancing the treatment of diabetes by "insulin." Sir John Irvin moved a vote of thanks to Dr. Lawson. As chairman of the infirmary directors he also thought that the site would be presented to the infirmary when it moved to Forresterhill, and he understood a purchaser might be found for the present building.

GLASGOW UNIVERSITY.—The Senate has awarded Bellahouston gold medals to the following, who, having gained honours for the degree of M.D. in the year 1923, are, in the opinion of the Faculty of Medicine, worthy of this highest distinction for the excellence of their theses:—

Grace Hay Anderson: The calcium and phosphorus content of the blood in normal and rachitic children. John Norman Cruickshank: Syphilis and pregnancy.

JUNIOR EDINBURGH CLUB.—The fifteenth dinner of the club was held on Jan. 24th at the Boulogne Restaurant, Soho, with Dr. Hugh Paterson in the chair, when there was a large muster of members. Informal dinners are held monthly during the winter, and membership is open to all recent graduates of Edinburgh University. The hon. secretary is Dr. R. Scott Stevenson, 30, New Cavendish-street, W. 1.

THE LATE DR. JAMES HITCHCOCK.—The death occurred on Jan. 27th of Dr. James Hitchcock, of Gerrard's Cross, in his sixty-seventh year. He graduated M.B., C.M. at Aberdeen University in 1880, and was untiring in his devotion to his profession in the field of general practice. He published several articles in various medical journals, among them a prize essay on constipation in the *Practitioner*.

LONDON NEUROLOGICAL CLINIC.—The sixth annual dinner of the medical staff of the London Neurological Clinic (Ministry of Pensions) was held at Princes Restaurant, Piccadilly, on Jan. 26th. Between 40 and 50 past and present members took part. The guests included Lord Dawson of Penn, Lieut.-General Sir William Furse, Sir John Collie, Sir William Willcox, Sir Crisp English, Dr. Harry Campbell, and Dr. T. Beaton. In proposing the health of the Clinic, Dr. Laing Gordon spoke of the confidence of the staff in the future of psychotherapy, their enthusiasm for the cause of mental hygiene, and of the justification for these feelings found in the results of treating 15,000 cases grouped as "neurasthenia" and incipient mental disorder. He paid tribute to the enlightened policy of the Ministry in the care of the "shell-shocked," and to those who had guided it in the establishment and maintenance of the Clinic—in particular, Sir John Collie, Dr. W. A. Brend, and Dr. H. E. Davison. Sir Charlton Briscoe in the chair, in the absence of Dr. Davison, stated that the attendances of pensioners for treatment up to date amounted to over 200,000: and 51,000 had attended for diagnosis and the recommendation of suitable treatment. In replying for the Clinic, Sir Charlton Briscoe traced its growth from its birth in 1917 at Lancaster Gate. The toast of the guests, coupled with the names of Lord Dawson and Sir William Furse, was proposed by Dr. Travers Smith, who pointed out that if the need for psychotherapy amongst pensioners were decreasing, the success of the Clinic made all the more evident the urgent necessity for similar clinics for civilians. Lord Dawson, from his abilities, opportunities, and responsibilities, was generally regarded as the profession's spokesman and referee, and knowing his interest in the subject of team-work the profession would be well content to leave that of psychotherapeutic clinics in his hands. Lord Dawson said: "This Clinic is of value because it sets the pace, embodies an idea, carries it out well. Its repute has gone far and wide. It bears testimony to that widening reasoning which is ever spreading out over our profession and developing a power of working together which we did not exercise before the war." Lord Dawson then entered a plea for more coöperative work within the profession, and pointed out that the danger to be guarded against might be the risk to the individual spirit. "Anything which made us work according to pattern, turned us into officials rather than doctors, would tend to our destruction." Organisation must preserve adequate freedom for the individuality of the practitioner. Apart from its intrinsic value, the Clinic might be well worth preservation as a concrete object-lesson in what team-work should be. It was "an outstanding example, but we have still a lot to learn in the way of settling a clear policy and standing by it." Sir William Furse, speaking as the Regional Director and a layman, expressed his gratitude to the Clinic for its very valuable services to the ex-Service man.

DONATIONS AND BEQUESTS.—Mr. Henry Dixon Phillips, of Ipswich, left £250 to the East Suffolk and Ipswich Hospital; Mr. James Harris, of Swansea, left £100 to the Swansea Hospital; Mrs. Eliza Anne Glass left £500 to the Bristol Eye Hospital and £100 to the Bristol Royal Infirmary, and, subject to certain interests, the residue of the estate of the gross value of £32,636 is left as to one-third between the Bristol Eye Hospital and the Bristol Royal Infirmary.—Mr. George Cholmeley Cattlin, of Hove, who left £89,134, bequeathed £500 each to the Moon Society for the Blind, Brighton, the Society for the Relief of the Widows of Medical Men, Lloyds Benevolent Fund, the Sussex County Hospital, Epsom College, St. Bartholomew's Hospital, the London Hospital; £300 each to the Brighton, Hove, and Preston Dispensary, the Charity Organisation Society, Brighton Branch, the Surgical Aid Society, the Brighton, Hove, and Preston Dental Hospital, the Brighton, Hove, and Preston Throat and Ear Hospital, the Alexandra Hospital for Children, Brighton, and the Sussex Eye Hospital; £200 each to Dr. Barnardo's Homes, Hove Branch, St. Barnard's Home, Hove, the Royal Hospital for Incurables, Putney. The residue of his property, after various bequests and annuities, to the before-named charities pro rata in accordance with the amount of their legacies.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, W.

THURSDAY, Feb. 7th.—4.30 P.M., Papers to be read: J. W. Pickering, D.Sc., and J. A. Hewitt, Ph.D.: Further Experiments on the Action of "Peptone" on Blood, with Notes on the Significance of Surface Phenomena in the Problems of Anaphylaxis and Susceptibility. (Communicated by Prof. W. D. Halliburton.)—L. B. Winter and W. Smith: Studies on Carbohydrate Metabolism. I. Variations in the Nature of the Blood-sugar. (Communicated by Prof. F. G. Hopkins.)—E. C. Grey: The Latent Fermenting Powers of Bacteria. Parts I., II., and III. (Communicated by Prof. A. Harden.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Feb. 4th.

TROPICAL DISEASES AND PARASITOLOGY: at 8.30 P.M.

Paper:

Dr. J. Gordon Thomson: Recent Investigations in Rhodesia in Blackwater Fever.

Communications:

Dr. A. H. Skinner (Hankow): Schistosomiasis Japonica: the Diagnosis of Early and Mild Infections.

Mr. M. L. Treston (Burma): A Case for Diagnosis: (?) Anthrax Bacilli found in the Spinal Fluid in a case of Paralysis of the Lower Limbs.

Cases and Specimens:

Dr. J. B. Christopherson: (1) Cases of Actinomycosis in the Parotid Region from Teheran; (2) Actinomycosis, Granules Stained (from case shown).

Dr. Carlos Franca: The Intermediary Host of Schistosoma Japonicum in Formosa (*Blanfordia Nosophour formosana*).

Dr. Mendoza Guazon: (1) Bottle Specimen of Papillomatous Schistosomiasis of the Rectum (Philippines); (2) Section from Liver: Ascaris Infection.

Tuesday, Feb. 5th.

ORTHOPÆDICS: at 5.30 P.M. (Cases at 5 P.M.)

Cases will be shown.

Paper:

Mr. J. W. Dowden: The Principle of Early Active Movement as Applied to Fractures of the Upper Extremity.

PATHOLOGY: at 8.30 P.M.

Laboratory Meeting at 8.30 P.M. at St. Bartholomew's Hospital.

Demonstrations, &c.:

Dr. R. L. Mackenzie Wallis: Intermittent Cystinuria.

Dr. R. R. Armstrong: Experimental Prophylaxis of Sensitised Pneumococcal Vaccine.

Dr. M. Donaldson and Dr. R. G. Canti: (1) Demonstration of Microphotographic Incubator designed for the Study of the Action of Radium on Tissues growing in vitro; (2) Microscopical Demonstration: Carcinoma of the Cervix Uteri treated with Radium.

Dr. T. H. G. Shore: Demonstration: The Application of Gelatin to Museum Technique.

Dr. H. E. Archer: Demonstration: The Estimation of Blood Urea.

Dr. L. P. Garrod: Quantitative Method of Cultivating Fæces.

Sir Bernard Spilsbury: Demonstration: Rhabdo-myosarcoma.

Wednesday, Feb. 6th.

SURGERY: at 5.30 P.M.

Paper:

Mr. Grey Turner: Some Encouragements in the Surgery of Malignant Disease.

Thursday, Feb. 7th.

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.

Short Communications:

Mr. F. Winson Ramsay: Notes on a case of Normal Pregnancy after Operations for Ectopic Pregnancy on both Fallopian Tubes.

Dr. J. P. Hedley: An Unusual Case of Chorion Epithelioma (with specimen).

Dr. J. D. Barris: Dysmenorrhœa due to Hæmatometra in the Rudimentary Horn of a Bicornute Uterus.

Paper:

Mr. Comyns Berkeley, Mr. E. C. Dodds, and Mr. A. L. Walker: Some Chemical Observation on the Toxæmias of Pregnancy, with special reference to Hepatic Function.

Friday, Feb. 8th.

CLINICAL: at 5.30 P.M. (Cases at 5 P.M.)
Cases:
Dr. Stanley Melville: Case for Diagnosis.
Dr. C. F. T. East: Case of Morbus Cordis.
Dr. Douglas Firth: Red-headed Albinos.

OPHTHALMOLOGY: at 8.30 P.M. (Cases at 8 P.M.)
Cases will be shown.
Papers:
Mr. Basil Lang: A Modification of the Usual Method of Extraction of Lens in Senile Cataract.
Mr. Malcolm Hepburn: A Classification of Affections of the Choroid.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Feb. 6th.—4 P.M., Dr. S. Vere Pearson: Pulmonary Tuberculosis—Early Diagnosis of the Disease.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.
POST-GRADUATE COURSE: FEBRUARY–MARCH, 1924.
CLINICAL LECTURES AND DEMONSTRATIONS.
MONDAY, Feb. 4th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Hemiplegia, Varieties and Localisation: Dr. Kinnier Wilson.
TUESDAY, Feb. 5th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Paralysis Agitans: Dr. Walshe.
THURSDAY, Feb. 7th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Post-encephalitic Conditions: Dr. Walshe.
FRIDAY, Feb. 8th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Recent Studies on the Vestibular Nerve: Mr. Sydney Scott.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.
MONDAY, Feb. 4th.—12 noon, Neurosyphilis. I.: Dr. J. G. Greenfield.
The fee for the Course, including Pathology, is £5 5*s*. For those who hold Perpetual Tickets the fee is £3 3*s*.

COURSE OF LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given by Dr. Kinnier Wilson on Wednesdays and Thursdays at 12 noon, commencing Feb. 13th.
The fee for this Course will be £2 2*s*.
Dr. F. M. R. Walshe will give A COURSE OF EIGHT CLINICAL DEMONSTRATIONS, CHIEFLY ON METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, in the Wards at 10 A.M., every Wednesday and Thursday during February. The numbers attending the Course will be limited. Fee £2 2*s*.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE NEUROLOGY OF THE EYES.
WEDNESDAY, Feb. 6th.—3.30 P.M., (I.) Papilloedema and Optic Neuritis: Mr. Leslie Paton.
The fee for this Course alone is £5 5*s*. If taken in conjunction with the general Post-graduate Course the fee is £3 3*s*. All applications should be sent to the Secretary, Medical School.
Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.
Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.
J. G. GREENFIELD, Dean of Medical School.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W. 1.
MONDAY, Feb. 4th, to SATURDAY, Feb. 9th.—Combined Course on Diseases of Children. Clinical Demonstration and Lectures from 10 A.M. to 4.30 P.M. daily, including the VICTORIA HOSPITAL FOR CHILDREN, the PADDINGTON GREEN CHILDREN'S HOSPITAL, and the ROYAL WATERLOO HOSPITAL.—CENTRAL LONDON OPHTHALMIC HOSPITAL. Clinical Lecture Demonstration every afternoon. Mon., 2 P.M., Mr. Oliver. Tues., 2.30 P.M., Mr. Gibb. Wed., 2.30 P.M., Mr. Neame. Thurs., 2.30 P.M., Mr. Cunningham. Fri., 4.30 P.M., Mr. Williamson-Noble (Pathological).—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars. Clinical Instruction in the Out-patient Department every afternoon from 2.30 P.M. Tues. and Fri., 5.30 P.M., Venereal Clinic.—LONDON LOCK HOSPITALS. Clinical work daily. Lectures at Dean-street as follows: Mon., 5 P.M., Mr. Gibbs: Anterior and Posterior Urethritis. Tues., 2.30 P.M., Mr. McDonagh: Treatment of Gonorrhœa and Its Complications. Wed., 5 P.M., Mr. Juler: The Commoner External Venereal Diseases of the Eye. Thurs., 4.30 P.M., Mr. Abel: Treatment of Acute Gonorrhœa in the Male. Fri., 4 P.M., Mr. Abraham: Treatment of Gonorrhœa in the Female.—LONDON SCHOOL OF TROPICAL MEDICINE. Tues. and Thurs., 2 P.M., Special Clinical Demonstrations.—NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N. 15. Special Intensive Course, first week Feb. 4th to 9th. Demonstration and Cliniques from 10.30 A.M. to 4 P.M. daily. Clinical Lectures at 4.30 P.M. Mon., Mr. Banister: Some Problems in Pregnancy. Tues., Mr. Gillespie: Diagnosis of Intermittent and Chronic Swellings of the Knee-joint. Wed., Mr. Benians: The Present Position of Vaccine-Therapy. Thurs., Mr. Carson: Difficulties in After-treatment following Operation on the Abdomen. Fri., Dr. Crookshank: Pathogeny and Treatment of Migraine.—WEST-END HOSPITAL FOR NERVOUS DISEASES, at 73, Welbeck-street, W. Mon., 1.30 P.M., Dr. Campbell: Facial Paralysis, Neuralgia, and Other Disorders of Peripheral Nerves. Tues., 5 P.M., Dr. Scripture: Speech Disorders in Nervous Disease. Thurs., 1.30 P.M., Dr. E. D. Macnamara: Epilepsy and Other "Fits." Fri., 5 P.M., Dr. Worster-Drought: Encephalitis Lethargica.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
MONDAY, Feb. 4th.—5 P.M., Prof. K. Macfarlane Walker: The Internal Secretion of the Testis.
WEDNESDAY.—5 P.M., Prof. C. Max Page: The Surgical Treatment of Osteo-arthritis.
FRIDAY.—5 P.M., Prof. W. Heneage Ogilvie: The Infection of the Upper Alimentary Tract.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Feb. 4th.—10 A.M., Surgical Registrar: Surgical Anatomy. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Bishop Harman: Eye Dept.
TUESDAY.—12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards. 2.30 P.M., Dr. Pritchard: Medical Wards.
WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Owen: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Mr. Simson: Gynæcological Demonstration. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
FRIDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations and Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear..
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Feb. 7th.—4 P.M., Mr. Shires: X Ray Appearances in Diseases of the Joints.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
THURSDAY, Feb. 7th.—5 P.M., Mr. T. B. Davies: Acute Abdominal Pain in Pregnancy.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
TUESDAY, Feb. 5th.—5 P.M., Dr. Adamson: Streptococcal and Staphylococcal Eruptions.
THURSDAY.—5 P.M., Dr. J. L. Bunch: Tuberculosis.

CANCER HOSPITAL, Kensington, S.W.
WEDNESDAY, Feb. 6th.—4.30 P.M., Mr. P. P. Cole: Inoperable Cancer of the Uterus.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)
MONDAY, Feb. 4th.—(At the Children's Hospital.) Mr. Dun: Surgical Treatment of Tuberculous Glands.
TUESDAY.—(At the Southern Hospital.) Dr. Sanderson: Intrinsic Cancer of the Larynx and Ear and Nose Cases.
WEDNESDAY.—(At the Northern Hospital.) Dr. Leith Murray: Genital Prolapse.
THURSDAY.—(At the Stanley Hospital.) Mr. A Evans: The Acute Abdomen.
FRIDAY.—(At the Royal Infirmary.) Mr. Guthrie: Foreign Bodies in the Air- and Food-Passages.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
MONDAY, Feb. 4th.—4.15 P.M., Mr. S. R. Wilson: Recent Improvements in Anæsthesia.
TUESDAY.—4.15 P.M., Dr. A. Ramsbottom: Spastic Paraplegia.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE. (At Whitworth-street West Branch.)
FRIDAY, Feb. 8th.—4.30 P.M., Dr. C. P. Lapage: Rheumatism and its Allied Infections in Children.

ANCOATS HOSPITAL LECTURES.
THURSDAY, Feb. 7th.—4.30 P.M., Dr. G. L. Langley: Early Cardiac Complications of Rheumatism.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES.
TUESDAY, Feb. 5th.—(At the Royal Hospital.) 3.30 P.M., Mr. G. Simpson: Hypertrophy of the Prostate.
FRIDAY.—(At the Jessop Hospital.) 3.30 P.M., Mr. Chisholm: Acute Abdominal Pain in Pregnancy.

Appointments.

DICK, Major C., late R.A.M.C., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Superintendent of St. Mary's Hospital, Paddington.

HOSKIN, T. J., M.D. Camb., M.R.C.P. Lond., Assistant Physician, Royal Free Hospital.

HOWELL, B. WHITCHURCH, F.R.C.S. Eng., Consulting Orthopædic Surgeon to "Brookscroft" Voluntary Infant Welfare Centre, Walthamstow.

MACKENNA, R. W., M.D., Ch.B. Edin., Lecturer in Dermatology, University of Liverpool.

ODDY, H. M., M.B. Oxf., M.R.C.P. Lond., Assistant Physician to the Belgrave Hospital for Children.
WHARTON, J., M.D. Camb., Honorary Ophthalmic Surgeon, Manchester Royal Infirmary.
Surgeons under the Factory and Workshop Acts: GOVAN, G., M.B., C.M. Edin. (Cockermouth); LEGGE, S. B., M.D., Ch.B. Edin. (Shifnal).

Vacancies.

For further information refer to the advertisement columns.

Aylesford, Kent, Preston Hall.—Asst. M.O. £500.
Birkenhead and Wirral Children's Hospital.—H.S. £100.
Bedford County Hospital.—Asst. H.S. £130.
Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. £120.
Bournemouth, Holiday Home for Tuberculous Ex-Service Men.—Res. Med. Supt. £500.
Chesterfield and North Derbyshire Royal Hospital.—Jun. H.S. £150.
City of London Hospital for Diseases of the Heart, Victoria Park, E.—Radiologist.
Discovery Expedition.—S. £600.
Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £250.
Glamorgan County Mental Hospital, Bridgend.—Jun. A.M.O. £350.
Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—Anæsthetist.
Hospital for Sick Children, Great Ormond-street, W.C.—Cas. O. Also Asst. Pathologist. Each £400.
India, Women's Medical Service.—Medical Woman. Rs.550 p.m.
Kent County Ophthalmic Hospital, Maidstone.—H.S. £300.
Leicester Royal Infirmary.—Second Res. Anæsth. £200.
London Lock Hospitals, 283, Harrow-road, W., and 91, Dean-street, W.—Hon. Ophth. S.
London (Royal Free Hospital) School of Medicine for Women.—First Asst. in Obstet. and Gynæcol. Unit. £700.
Lowestoft, St. Luke's Hospital.—Jun. Asst. M.O. £500.
Malay States.—M.O.'s. and Health O.'s. £616.
Manchester Hospital for Consumption, &c.—Res. M.O. £300.
Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Asst. Cas. O. £100.
Northampton General Hospital.—H.S. £150.
Nottingham General Hospital.—H.S. £200. Also Res. Cas. O. £250. H.P. £200.
Orkney, Parish of Eday.—M.O. £280.
Plymouth, Devon and Cornwall Sanatorium for Consumptives, Didworthy, South Brent.—Res. Med. Supt. £550.
Queen Mary's Hospital for the East End, Stratford, E.—Hon. Asst. P.
Royal Earlswood Institution, Redhill, Surrey.—Jun. Asst. M.O. £250.
Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Three Hon. Anæsthetists.
Salford Royal Hospital.—Pathological Asst. £260. Also Lady Supt. of Nurses. £250.
St. Marylebone Hosp., Ladbroke-grove, W.—Third Asst. M.O. £300.
St. Thomas's Hospital.—P. to Out-patients.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Cas. O. and Reg. £150.
West London Hospital, Hammersmith-road, W.—Hon. Med. Reg., Hon. Surg. Reg., and Hon. Obstet. Reg.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Barnet, Herts; Peasenhall, Suffolk; St. Blazey, Cornwall; Crewkerne, Somerset.

Births, Marriages, and Deaths.

BIRTHS.

BURNHAM.—On Jan. 26th., the wife of C. Burnham, M.B., Ch.B., F.R.C.S.E., of a daughter.
CARNEY.—15th Jan., at Errigle, Cootehill, Co. Cavan, the wife of Major P. Carney (late R.A.M.C.), of a son.
REID.—On Jan. 11th, at New Barns, Yalding, the wife of Captain S. D. Reid, R.A.M.C., of a daughter.

MARRIAGES.

COPP—FENTON.—At Holy Trinity, Sloane-street, on Jan. 22nd, Evelyn May, the elder daughter of the late Rev. Charles Copp, Silverton, Devon, to Henry Felix Fenton, Medical Superintendent, Worcester County and City Mental Hospital, son of the late Dr. H. A. Fenton, of Hatfield, Nth. Doncaster.

DEATHS.

BALE.—On Jan. 27th, at 5, College-gardens, London, N., Henry James Bale, Founder and Managing Director of Bale, Sons and Danielsson, Medical Publishers, aged 76 years.
CREAGH.—On Jan. 18th, at Grangewood Lodge, Netherseal, William Creagh, Brigade Surgeon-Major, attached Royal Horse Artillery, third son of the late Lieut.-General James Creagh, in his 86th year.
DE JONG.—On Jan. 18th, from pneumonia, Oscar de Jong, M.B., Ch.B., D.P.H., of Rodney-street, Liverpool.
MACNICOL.—On Jan. 26th, at Queen Alexandra's Military Hospital, Millbank, Major Robert Henston MacNicol, R.A.M.C.
SHULDHAM.—On Jan. 23rd, at Priory-court, N.W., Edward Shuldham, M.D., M.A. Oxf., aged 86.
SMITH.—On Jan. 26th, at Ranelagh-avenue, Hurlingham, John Alexander Smith, L.D.S. Eng., in his 86th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE HISTORY OF PERCUSSION AND AUSCULTATION.[1]

BY SIR WILLIAM HALE-WHITE, M.D., F.R.C.P. LOND.

IN the investigation of disease we doctors probably use percussion and auscultation more than any other means, yet had this meeting been held a hundred years ago it is most unlikely that a single person present would have known anything about them, for they had only come into use four or five years before in France, and Forbes's translation of Laënnec's book was not published in England until 1821.

Leopold Auenbrugger and Percussion.

Percussion we owe to Joannes Leopold Auenbrugger (1722–1809), who studied medicine at the University of Vienna, one of his teachers being Baron von Swieten. Auenbrugger appears to have early shown a talent for observation, and obtained his doctor's degree in 1752. The little book of 95 pages on which his fame rests was first published in 1761; a second unaltered edition appeared in 1763. It is written in Latin, and the pages are so widely spaced that the whole book only contains about 7000 words—that is to say, it could all appear in five or six pages of THE LANCET. It is entitled "Inventum Novum ex Percussione Thoracis Humani ut Signo abstrusos interni Pectoris morbos detegendi." The text consists of 48 sections, each numbered; these are grouped, not into chapters, but into "Observations"; there are 14 such groups. After most of the sections there appears a Scholium or Annotation. Thus:

"OBSERVATION II.

On the Method of Percussion.

IV.

The thorax ought to be struck, slowly and gently, with the points of the fingers, brought close together and at the same time extended.

Scholium

Robust and fat subjects require a stronger percussion; such, indeed, as to elicit a degree of sound equal to that produced, by a slight percussion, in a lean subject."

Statements of great importance were that disease exists if the percussion note is different in similar places on the two sides, and if it is on both sides equal but diminished in intensity; that the superficial extent of the unnatural sound in a sonorous region is commensurate with the extent of the morbid affection; that if the same results are obtained both before and behind, on points precisely opposite, the disease occupies the whole diameter of the chest. Corvisart justly says nothing can be clearer, more precise or more true, than the preceding paragraphs. Auenbrugger then tells us that a morbid sound always accompanies a copious effusion of fluid in the thoracic cavity; that such a sound perceived during the course of acute diseases of the chest, occurs most frequently in inflammatory affections—the duller the sound the more severe the disease, the more extensive the dull sound the greater the danger. The ninth observation is entitled "Of the appearances on dissection, in cases in which the preternatural sound of the chest has been observed." These are the following: (1) Scirrhus of the lungs; (2) the conversion of this into an ichorous vomica; (3) a purulent vomica (simple or ruptured), in the pleura, lungs, mediastinum, or pericardium; (4) empyema; (5) Dropsy of the chest in one or both cavities; (6) dropsy of the pericardium; (7) extensive extravasation of blood in the cavity of the pleura or pericardium; (8) aneurysm of the heart. Corvisart's commentary on this is worth quoting: "Of the surpassing importance of a knowledge of these no one can doubt; and when it is considered that percussion—and percussion alone—can make us acquainted with them, we cannot sufficiently applaud those men who have enriched this, the most difficult department of medicine, with a kind of knowledge at once so scientific and satisfactory."

It is strange to see that in 1761 so distinguished a physician as Auenbrugger gathered together all varieties of solidification of the lungs under the one word scirrhus, and that all varieties of cardiac dilatation were included in the phrase "aneurysm of the heart." We have here an indication of the backwardness of medicine at that period, but it is interesting to observe that he knew that a phthisical cavity gives a dull note, and, greatly to his credit, he not only discovered percussion, but also knew from dissection the diseases in which the dull note is given. The remaining observations are occupied with the symptoms of these eight

[1] An abstract of an address delivered before the Midland Medical Society at Birmingham.

conditions. Short as his little book is, it might be much condensed, for Auenbrugger's fame rests on the few paragraphs in which he announces the discovery of percussion, states where in health the note is sonorous, where it is dull, and teaches us in what diseases it is dull.

Reception of Auenbrugger's Work.

There is no doubt that Auenbrugger's work did not fructify until Corvisart published his admirable commentary. This was due to two causes: Auenbrugger was a court favourite and his jealous colleagues would not pay attention to his discovery; also, he did nothing to help the seed to grow. There is no evidence that he was, like Laënnec, a great teacher who by lecture and bedside demonstration was always forwarding his discovery, or that he was a great physician interested in all branches of medicine. He appears rather to have the good luck to hit upon the discovery of new means of diagnosis. As far as we know, only two people of importance took any interest in Auenbrugger's book during his lifetime—namely, Albrecht von Haller and the Leipsic professor, Christian Gottlieb Ludwig. Letters written by Auenbrugger to Haller exist, as also does one of condolence to Haller's son on the death of the great physiologist. But neither of these two famous men did much to further the discovery of percussion. Speaking generally, the discovery fell dead, as will be seen by reference to Neuburger's recent work [2] on Auenbrugger.

In France in 1770 Rozière de la Chassagne published, with a work of his own, "Manuel des pulmoniques, ou Traité complet des maladies de la poitrine," a translation of Auenbrugger's book, but this, too, attracted no attention. But in 1788 Corvisart, having heard of Auenbrugger's discovery, began to practise it. In 1808, a year before Auenbrugger's death, Corvisart published a translation of the "Inventum Novum," praised the method, and added commentaries of his own, so that the little book of 95 pages became one of 440. This remarkable book shows that Corvisart fully understood the art of percussion, and wherever Auenbrugger is correct he is awarded unstinted praise; where his knowledge of medicine is at fault he is corrected. Laënnec was enthusiastic in praise of percussion, saying, "La percussion de la poitrine est, sans contredit, l'une des découvertes les plus précieuses dont la médecine se soit jamais enrichie." Thanks primarily to Corvisart, but largely to Laënnec, Auenbrugger at last gained, not in his own country, but in France, the recognition due to a great discoverer. In Great Britain he was introduced to the profession by John Forbes, who in 1824 published "Original cases with dissections and observations illustrating the use of the Stethoscope and percussion, in the diagnosis of Diseases of the Chest," which book contained a translation of Auenbrugger's original treatise and a selection of Corvisart's commentaries.

Laënnec and Auscultation.

Auscultation was discovered by René Théophile Hyacinthe Laënnec, who was born at Quimper in 1781. His father was temperamentally quite unfit to look after a family, and Laënnec owed his opportunity in life to a paternal uncle, Guillaume, a physician of high intelligence, learned and industrious, who studied in England under Hunter and became Rector of the University of Nantes.

Young Laënnec.

He entered at the School of Medicine at the Hôtel Dieu, Nantes, in September, 1795, being then 14½ years old. It is an indication of the times to find that in the same month he was appointed military surgeon of the Third Class. In 1800 he received the appointment of Officier de Santé and accompanied the expedition sent to quell the insurrection in the Morbihan district. In that year he should have gone to study medicine in Paris, but lack of money prevented him until, in 1801, thanks to his uncle, enough was wrung from Laënnec's father to enable him to do so.

What he did during the remaining 25 years of his life would in any circumstances arouse our wonder, but his accomplishment appears marvellous when we remember that two millstones hung round his neck. The first was his wretched health; he suffered from asthma, angina, neurasthenia, and later from phthisis, and more than once he nearly gave up his career in Paris for a life in the country. The second was his father, whom at last he had partially to support. When Laënnec entered the Ecole de Médecine there were in Paris two schools of thought: that of Pinel, at La Salpêtrière, was the more popular, but was theoretical and interested chiefly in the classification of disease; the other, headed by Corvisart at La Charité, took morbid anatomy as its foundation. The latter attracted Laënnec, and he entered as a student at La Charité, becoming there a fast friend of Bayle. He was a great taker of notes, and during his first three years drew up a minute history of nearly 400 patients. He, Bayle, and Dupuytren were all enthusiastic in the study of morbid anatomy and decided to write a book on the subject, but the project fell through; Laënnec then determined to write one himself, but never completed it. His earliest publication was a description of a case of mitral disease published in 1802.

In September, 1803, he was awarded the Grands Prix in both surgery and medicine. His surgical commentary has been preserved; the subject is axillary aneurysm, for which he favoured amputation at the shoulder. In 1804 he presented a thesis on the application of the doctrines of Hippocrates to practical medicine and four days later received his diploma. The thesis, dedicated to his uncle Guillaume, was printed and attained great success. In his first year of private practice he earned 150 francs, in the second 400; by 1813 he was earning 10,000 francs a year from practice and had attained the position of a fashionable physician. Nevertheless, he continued to work hard in the wards and at the science of medicine, particularly morbid anatomy, so that by the age of 25 he was generally recognised as a chief among morbid anatomists. His power of work was prodigious, for in addition to his medical activities he studied the Breton language, including its relationship to Cornish, Erse, and Gaelic. In 1814 the Parisian hospitals were full of soldiers; Laënnec put those from Brittany, who spoke no French, in separate wards, himself looking after them.

All this time he was perfecting the art of auscultation in the wards of the Necker Hospital; in February, 1818, he read, before the Academy of Sciences, an account of his new method of investigating the respiratory and cardiac sounds, and later on in this year he gave four lectures on the same subject. A few months later still he was able to announce his discovery of ægophony and pectoriloquy. But it is quite likely that all he had done would have remained buried if he had not gathered his observations into that masterpiece "De l'Auscultation Médiate ou Traité du Diagnostic des Maladies des Poumons et du Cœur fondé principalement sur ce nouveau moyen d'exploration," published in two volumes in Paris during August, 1819, at the price of Fr.13. The publishers gave him 7000 francs for the first two editions. A stethoscope cost 3 francs.

In 1818 and again in 1819 Laënnec was very ill; for two years he lived in Brittany, returning to Paris in better health for a further four and a half years of strenuous work. In December, 1821, he started a course of clinical instruction at the Necker Hospital; in 1823 he took charge of the clinic at La Charité; his rounds began at 10 A.M. on five days a week and each lasted two hours. About 50 learners accompanied him, among them many foreigners, for his reputation was European. Most of the time he talked in Latin and he wrote his observations on the cases in this language. In August, 1822, he was elected professor and royal lecturer at the College of France, a post he held till he finally left Paris. Private patients flocked to him in such numbers that he had to restrict himself to consulting practice. He entirely re-wrote his book, publishing a second edition; and in 1821 he married. His health got worse and worse; he recognised that he had phthisis, and in May, 1826, he left Paris for Brittany, where he died in August of the same year.

Laënnec, although he was never actually in England, appears making stethoscopes in Kipling's "Marklake Witches."

"I saw him (René) and Jerry sitting on the seat and playing with wooden toy trumpets . . . They weren't real trumpets because Jerry opened his shirt collar, and René put one end of his trumpet against Jerry's chest, and put his ear to the other. Then Jerry put his trumpet against René's chest, and listened while René breathed and coughed.

"'This holly wood is one of the best,' said Jerry. 'Tis wonderful like hearin' a man's soul whisperin' in his innards but unless I have a buzzin' in my ears, Mosheur Lanark, you make much about the same kind of noises as old Gaffer Macklin—but not quite so loud as young Copper. It sounds like breakers on a reef—a long way off. Comprenny?'

"'Perfectly,' said René. 'I drive on the breakers. But before I strike, I shall save hundreds, thousands, millions, perhaps, by my little trumpets.'"

The Discovery of Auscultation.

In the first edition of Laënnec's book we are told, in the following words, how he was led to the discovery of mediate auscultation.

"In 1816 I was consulted by a young woman presenting general symptoms of disease of the heart . . . The patient's age and sex did not permit me to resort to the kind of examination I have just described (i.e., direct application of the ear to the chest). I recalled a well-known acoustic phenomenon—namely, if you place your ear against one end of a wooden beam the scratch of a pin at the other extremity is most distinctly audible. . . Taking a sheaf of paper I rolled it into a very tight roll, one end of which I placed over the præcordial region, whilst I put my ear to the other. I was both surprised and gratified at being able to hear the beating of the heart with a much greater clearness and distinctness than I had ever done before by the direct application of my ear."

Then follows an account of his experiments as to the best material for making stethoscopes; he finally found that

[2] Leopold Auenbrugger's Inventum Novum. Max Neuburger. Vienna and Leipzic, 1922.

wooden cylinder with a tube bored down its long axis was the best, the tube being expanded into a funnel-shaped depression at one end. He next tells us how to use the instrument.

Part I. of the book treats of the investigation of the voice sounds by the stethoscope. Laënnec was struck by a most singular phenomenon in a young woman 28 years old, for on listening to the stethoscope applied to a spot under the middle of the right clavicle "her voice seemed to issue directly from the chest and to pass unaltered through the central canal of the instrument." He found this sign in 20 other hospital patients and in all who died a cavity was present where the pectoriloquy, for so he called the sign, had been heard. Thus the discovery of pectoriloquy and its significance was made. Later on, in the chapter on pulmonary phthisis, he tells us that that he "examined post mortem 200 phthisical subjects . . . and on no single occasion failed to find cavities in any part of the lung over which pectoriloquy had been clearly audible." Therefore, he says, "pectoriloquy is a true pathognomonic sign of phthisis."

In Chapter 4 of Part I. he announces the discovery and meaning of ægophony, which resembles pectoriloquy. The voice appears high-pitched, sharp, and silvery, and is quavering and jerky, like the bleating of a goat. He says, "its occurrence appears to me to be restricted to subjects suffering from acute or chronic pleurisy, with a limited amount of effusion in the pleural cavity."

In Part II. we find an account of the investigation of respiratory sounds by the stethoscope as accurate and true to-day as when he wrote it. Part III. begins with an account of râles. They are classified as (1) moist râle or crepitation; (2) mucous râle or gurgling; (3) dry sonorous râle or snoring; (4) dry sibilant râle or whistling. We are told that dry sonorous râles "not infrequently resemble the cooing of a dove. This resemblance is often so close that one is tempted to believe that a dove is hidden under the patient's bed."

The greater part of the two volumes is occupied by diseases of the lungs, but consideration is given to the stethoscopic examination of the heart. Laënnec always supports his statements by illustrative cases, of which the appearances during life and after death are admirably described.

The Place of Laënnec in Medicine.

Before the beginning of the nineteenth century, medicine was almost entirely either empirical or dominated by metaphysical conceptions. Laënnec's book came as a revelation, causing the scales to fall from the eyes of doctors; it taught them that medicine, like other sciences, rests on observation and experiment. He and a few other great men have had the power of observation exalted to such a degree that it becomes genius, a rare gift far less common than high thinking. Verily does Sydenham say: "True practice consists in the observations of nature; these are finer than any speculations." In this astonishing book there occur perfect, precise, and original descriptions of clinical symptoms and post-mortem appearances, neither too long nor too short, for the most part as true now as on the day they were written. Many of them refer to conditions till then unknown, or at least not properly appreciated, such as pulmonary tuberculosis, pneumonia, pulmonary apoplexy, pulmonary œdema, pulmonary gangrene, emphysema, bronchiectasis, hydrothorax, pneumothorax, and some forms of cardiac disease. Laënnec had the power which enabled him to combine isolated observations as to see what they indicated when grouped together; not only did he draw accurate and vivid pictures of the signs and symptoms of particular diseases, but by carrying his gift for clear vision into the post-mortem room he showed that it was possible to predict from observations made during life what would be found after death. He may be said to have been one of the founders of the clinical-morbid anatomy method of studying disease, which, although other methods have since been added, still remains the corner-stone of medicine.

TALKS TO MOTHERS.[1]

WE have received a further instalment of the excellent leaflets by Miss Lily Skene, with the above title, these including Nos. 3 to 6 in the two series dealing respectively with infant care and with character training. While the style in which the leaflets are written is homely, the advice given is uniformly good. The new leaflets on infant care include talks on the care of the premature baby, on summer diarrhœa, on the causes and prevention of constipation, and on the causes and prevention of sickness and loose stools, while the "character" series deal with such topics as unselfishness, honesty, and patience. The practical character of the teaching and the simplicity of the language—to say nothing of the modest price—should ensure for these little papers the wide popularity among nurses and health visitors which they deserve.

[1] Series I. and II., Nos. 3–6, inclusive. By Lily Skene. London: John Bale, Sons, and Danielsson. 1923. 2*d.* each.

COLONIAL HEALTH REPORTS.

St. Helena.

THE estimated civil population on Dec. 31st, 1922, amounted to 3658. The birth-rate in 1922 was 25·88 per 1000, as against 25·3 in the previous year. The death-rate was 9·87 per 1000, as compared with the exceptionally low rate of 6·5 in 1921; this may be taken as working back to the average of about 8·5 per 1000. The general health of the community continued to be satisfactory; influenza of a mild type prevailed in the months of January and February to a moderate extent. A case of measles, complicated by appendicitis, was landed from a mail steamer in January and taken to the hospital, and a severe case of diphtheria occurred in Jamestown in March, but no further cases followed in either instance. A medical examination of all the island children was carried out during the year. The town school-children showed a lower state of nutrition than those in country schools. The proportion of children showing defective teeth would compare most favourably with similar children in England. The vast majority of younger children showed excellent teeth. Cases of enlarged tonsils and adenoids were conspicuous by their absence. There were 174 admissions to the hospital (as compared with 197 in 1921), and there were four deaths. The mean temperature for the year was 61·1° F. The total rainfall measured at Hutts Gate was 42·83 inches, at Plantation 37·12 inches, and in Jamestown 7·55 inches.

New Hebrides.

Mr. M. King, C.M.G., the British Resident Commissioner, in his report to the Colonial Office for 1921–22, explains that the New Hebrides, to which are attached the Banks and Torres Islands, have an area of about 5700 square miles. The natives are Melanesians, but in places there is a mixture of Polynesian blood. A joint naval commission was established in 1888, by agreement with France, to protect the lives and property of British and French subjects and to maintain order. By a Convention of 1906 a condonium was set up with a joint court composed of British and French judges and a neutral president, and an executive government consisting, for some purposes, of the British and French representatives in the group acting in concert. For other purposes British and French nationals remain subject to the control only of their national authorities. The British and French Resident Commissioners are subordinate to the High Commissioner for the Western Pacific and the High Commissioner at Nouméa respectively. A memorandum contributed by Dr. G. Vernon Davies, D.S.O., medical superintendent of the Paton Memorial Hospital, Vila, states that the following diseases are endemic: tuberculosis, malaria, filariasis, amœbiasis, and yaws. These five are, with pneumonia, to which the native is very subject, the chief causes of sickness in the group. Cerebro-spinal fever, influenza, whooping-cough, and mumps have appeared in epidemic form either in 1921 or 1922. The group appears to be free from enteric, plague, cholera, small-pox, yellow fever, bacillary dysentery, and diphtheria. Tuberculosis is the most serious disease that the natives are infected with; it accounts for one-third of all deaths that occur in the hospital. Besides the pulmonary disease, which is the most common, inflammation of the cervical glands is often met with. These show a tendency to very early suppuration. Tuberculous joints and meningitis also occur commonly. The habits of the natives, with a large family living and sleeping in a one-roomed grass house, provides an ideal means of spreading the infection. Malaria is the most widespread disease. Judging by the size of spleen in the native babies few of these escape. All natives are subject to it throughout their lives, but the value of quinine is becoming more recognised throughout the native population, and it is now in demand by all who have seen its good results. Among non-natives malaria is the greatest cause of ill-health, the majority of Europeans suffering from it at intervals. Blackwater fever occurs among Europeans in some islands, notably Epi. Filariasis is distributed throughout the group, but the incidence in the population varies very much in different parts. In some villages in Malekula, between one-third and one-half of the people are suffering from elephantiasis. Muscular swellings, many of which go on to abscess formation, occur very frequently among the natives, and are an important source of ill-health and incapacity. These are probably of filarial origin, though this is one of the things requiring investigation. One or two cases of filaria have occurred among the white population. Amœbiasis remains epidemic throughout the year, but shows a distinct tendency to be epidemic in January and February when flies appear at their worst. It is an important cause of death, attacking and proving fatal in all ages down to infancy. However, the people are recognising the good results that can be obtained with emetine, and it is usually one of the diseases that they will come to the hospital for when they are within reach of attention. It is difficult to

estimate the extent to which yaws exists among the native population. Few babies seem to escape, and sequelæ are seen in several forms among the adults. Gangosa is very often seen. A form of periostitis is very common. It seems to be described as a complication of yaws, but has occurred in Europeans after several years' residence who have had no sign of the primary disease. The tibia is the bone most often affected, but almost any bone seems subject to it, especially those forming the elbow-joint. The neosalvarsan drugs, which are so efficacious in the other manifestations of yaws, seem to have little influence on it, but it responds to potassium iodide. This bone lesion occurs in about 10 per cent. of the people in some villages. Besides the diseases mentioned there are others which do not occur so frequently. Tetanus appears from time to time. Leprosy is scattered about the group, and probably not one of the larger islands is without it. So far these cases have not been isolated or treated except on one island. Syphilis appears to be very rare, but gonorrhœa is becoming increasingly common; ulcerating granuloma is also met with. Tropical ulcer is very prevalent, and this and scabies are the only two skin complaints that interfere with the efficiency of the native. Hookworm has never been investigated in the group, but if this were done it is probable that, as in other islands, a large percentage of the natives would be found affected. Dr. Davies adds that these notes "are based on clinical grounds only, as so far little has been done here in the way of investigating disease. . . . . It is to be hoped that before long the fact that these islands are still virgin soil pathologically will attract a small laboratory."

A HOBBY FOR NATURE-LOVERS.

THE convalescing patient who has been ordered a prolonged sojourn in the country often finds his interest flagging through lack of a suitable hobby. Golf demanding too great an effort, the days must perforce be spent in gentle rambles among the fields and woods, which all too soon, for the average city dweller, become objectless and dull. A medical man, himself in poor health, tells us of the benefit he found in the occupation of jotting down in a diary short notes about trees, wild flowers, garden flowers, birds, and insects. "This becomes a most fascinating pastime," he writes, "if it is pursued, not in an aimless fashion, but in association with the Phenological Committee of the Royal Meteorological Society. This committee issues yearly a very simple printed form of questions on which the dates of first noticing the appearances of certain plants, birds, and insects can easily be entered. Attention may be confined to one particular set of phenomena, and in some cases two or more friends might unite in filling up a schedule. The expense is limited to the cost of postage, and correspondents sending a sufficient number of observations are supplied gratis with a copy of the annual report. Further particulars may be obtained from one of the hon. secretaries of the committee, at Chartham Park, East Grinstead, Sussex." We recommend this purposeful hobby to practitioners as a suggestion in prescribing for the empty hours of convalescence.

HEROIC TREATMENT FOR HUNTERS.

WE have received from Mr. R. W. Burkitt, F.R.C.S. Irel., of Nairobi, a pamphlet of 24 pages on the treatment of disease for officials, missionaries, settlers, soldiers, and hunters in out-of-the-way parts of Africa remote from a doctor. Five subjects are dealt with—namely, malaria, blackwater, pneumonia, dysentery, and sun. The author's intention to give useful information for intelligent treatment at the early stages of certain diseases is sound enough, but the recommendations transgress the limits permissible for non-medical efforts. As an instance may be quoted some of the advice given as to the diagnosis and early treatment of pneumonia. ". . if the chest is struck smartly with the fist, a spot will be found which causes pain—later on there will be a bloody spittle coughed up." It is then recommended "if he is seen early in the disease, if he be an adult with a normal quantity of blood, he should be bled at once, a pint from one of the big veins of the elbow," further details of the operation being supplied. This and other advice seems to us too heroic to put into the hands of non-medical and non-critical readers.

THE INVESTIGATION OF MOSQUITOES IN ENGLAND.

TILL recently the investigations of the local government boards upon malaria contracted in England in 1917 dealt primarily with the well-known species of anophelines indigenous to Britain—*A. maculipennis* and *A. bifurcatus*. It was then suspected that an elusive tree-hole breeding species, *A. plumbeus*, was capable of transmitting malaria, a suspicion confirmed by laboratory experiments conducted at the Liverpool School of Tropical Medicine. This led to an inquiry addressed to the South-Eastern Union of Scientific Societies [1] upon the range and habits of this species. This work was materially assisted and stimulated by the late Mr. Arthur Bacot to whom a well-deserved tribute is paid. *A. plumbeus* is fairly common in Epping Forest as well as in Richmond Park; the adult insects being found most abundantly in the autumn months, even as late as November. The eggs are laid singly in holes in trees, especially beeches and hornbeams; the half-grown larvæ live throughout the winter. This species has been recorded from various localities in Surrey, from Gloucestershire, and the Isle of Man, and is probably very generally distributed throughout England. There are believed to be two broods in the year. *A. plumbeus* is a timid mosquito, which feeds voraciously on man if undisturbed, but is easily driven off. Probably in nature its normal hosts are birds and small mammals. It will be readily understood that the secretiveness of the habits and the often inaccessible situation of its breeding places render this mosquito most difficult to eradicate.

[1] Transactions of the South-Eastern Union of Scientific Societies, 1923, xxxviii. Preface by Clarence Tierney, D.Sc.

ROYAL ALBERT INSTITUTION, LANCASTER.

THIS charitable foundation was instituted in 1864 for the feeble-minded of the Northern Counties, mainly through the efforts of a former Lancaster physician, Dr. Edward Denis de Vitré. The fifty-ninth annual report contains an interesting retrospect of its history during over half a century and a statement of its present position, together with projects for its extension. During the year, on Sept. 28th, 1923, the quinquennial festival was celebrated and the foundation-stone of a new reception house to take the place of one now used as a tuberculosis sanatorium was laid. Two Commissioners of the Board of Control visited the institution in May, 1923, and commended the excellent work that was being carried on. The report points out that whereas on the occasion of the first quinquennial festival, held in 1873, there were only 141 patients resident, there are now 800 with a prospect of considerable addition when new buildings have been provided for custodial cases. The income in 1873 was £5523, to-day it is £55,042. Altogether 4200 patients have been dealt with in the institution since 1870, four-fifths being reported as improved, in many cases to the extent of earning their own living under kindly supervision, though in the majority even of improved cases discharged from the institution "after care" is essential for the maintenance of permanent benefit. Acknowledgments are made to the various local organisations for raising funds, and the retirement of Sir Charles Brown, for more than 50 years the hon. secretary of the Preston Committee, is chronicled with regret. The training in the workshops (for some dozen trades) has been very successful, and the farm and garden land now consists of 277 acres on which some of the older patients are usefully employed.

The report of Dr. W. H. Coupland, the medical superintendent, for the year ending March 31st, 1923, shows a total of 118 patients admitted, 36 discharged, and 19 died out of a daily average of 760 residents, equivalent to a death-rate of 2·5 per cent., the largest mortality being due to pneumonia in conjunction with influenzal and tuberculous infections. It is stated that for the previous year 1921–22 the death-rate was exceptionally low—only 4 of either sex. Reference is made to the question of the propriety of admitting to institutions under the Mental Deficiency Act patients who have suffered from encephalitis lethargica, and Dr. Coupland expresses the view that "if the damage to the brain is obviously permanent and the children are not above the age of 15 years, then it is justifiable to certify them under the Mental Deficiency Act." As a clinical interest, attention is called to a curious mal-development of the neck and upper thorax existing in one of the female patients as an example of the condition which has been described under the title "les hommes sans cou," but for which Sir Arthur Keith has suggested the term "brevicollis" as a preferable designation. The example at the Institution of this rare condition seems to be unique in respect of the existence of mental deficiency not noted in other cases reported. In conclusion, Dr. Coupland refers to the much discussed subject of sterilisation, and records his view "that it is *real* (eugenic) education that will bring this about, and then a well-instructed public opinion will not need to invoke the law of compulsion."

Prof. A. Kuliabko, of Tomsk University, Siberia, returns thanks to English friends who have sent him books and journals.

The Kind of Nurse She Wants.—In reply to several correspondents, the force of the arguments against two forms of registration was quite clear to us.

Mr. Samson Clark, of East Molesey, chairman of Samson Clark and Co., Ltd., the Advertising Service Agents of Mortimer-street, W., and former Parliamentary candidate for the Chertsey Division of Surrey, asks us to state that he is not in any way connected with someone of the same name, against whom a receiving order in bankruptcy was gazetted last Saturday.

An Address

ON THE

INFLUENCE OF LEAD ON NORMAL AND ABNORMAL CELL-GROWTH

AND ON CERTAIN ORGANS.

Delivered before the North of England Obstetrical and Gynæcological Society on Dec. 21st, 1923.

BY W. BLAIR BELL, M.D., B.S. LOND.,

PRESIDENT OF THE SOCIETY; PROFESSOR OF GYNÆCOLOGY AND OBSTETRICS IN THE UNIVERSITY; GYNÆCOLOGICAL AND OBSTETRICAL SURGEON, ROYAL INFIRMARY, AND HONORARY DIRECTOR, CANCER RESEARCH FUND, LIVERPOOL.

(*With Illustrative Plates.*)

I KEENLY appreciate the sympathetic attitude adopted by the Council in asking me to take as the subject of my Presidential Address the history and progress of our researches concerning the influence of lead on cell growth and the related issues into which we have been drawn. The history of our work is spread over so long a period of time, and the investigations have now covered a field so wide, that I can do no more than give a short summary of what has been done and of what we are endeavouring to do.

EARLY IDEAS AND INVESTIGATIONS.

It is difficult to fix the precise date when I myself first became actively interested in the question of the arrest of cell growth, for no one can be long in practice without giving anxious thought to this problem, the practical outcome of the solution of which may be an indication of a method for the treatment of malignant neoplasms. I must have begun seriously to consider the question between the years 1905 and 1909, for a short while ago among some old papers concerning research work of that period I came across the following memorandum:

"To investigate the cancer problem, by attacking it from the following standpoint.

The ovum is implanted in the uterine wall by a proteolytic action on the part of the trophoblast; but once there, the proliferation of the cells of the chorionic villi effect its further fixation.

Now, normally these chorionic cells reach a certain stage and do not invade the uterus further, but in certain abnormal conditions chorion-epithelioma (cancer) follows; that is to say, there is an unrestrained action on the part of these cells. Why?

Well, in the first place there is no evidence to show that chorion-epithelioma ever occurs before the expulsion or death of the fœtus (as in vesicular mole); consequently, it is a fair supposition that the fœtal circulation controls the abnormal growth of these cells.

Usually, of course, death of the fœtus means death and separation of these cells, but in some cases it means increase in their growth and malignant invasion. This, however, rarely follows full-term pregnancy, so we may infer that with the growth of the fœtus the growing vitality of these cells is gradually decreased.

It is worth investigating, therefore, whether the blood of the full-term fœtus contains any body which will produce death of the chorionic cells and abortion . . ."

The last few sentences of the memorandum, which was written for my own edification and not for publication, have been omitted, as they bear only indirectly upon the present issue. The document is signed and dated Nov. 14th, 1909.

In a few words this note indicates the lines along which I proposed in the first instance to attack the problem. Incidentally, I may say that the nature of chorion epithelioma precluded my viewing the "parasitic theory" of the origin of malignant disease with favour. Adami[1] some years previously, but unknown to me at the time, had adopted a similar argument.

My early experiments consisted of attempts to isolate from the fœtus the substance that is responsible for the inhibition of the chorion epithelium. I failed entirely. Nevertheless, I think success along these lines with more modern methods and more technical skill than I possess may still be possible. Although I recognise how important a part may be played by the elusive influence of cell correlation, I cannot dissociate this from continued control along the lines of cell differentiation. Quite recently it has been shown that highly specialised tissue elements removed from that control and cultivated artificially undergo dedifferentiation—that is, revert to an embryonic type—and that the addition to the culture of normal connective tissue causes the dedifferentiated cells to resume differentiated growth.[2] It will be remembered that in the human subject the chorionic epithelium shows a gradual and natural tendency to disappear as the period of gestation advances; but that in the rabbit the epithelium of this fœtal membrane not only invades the maternal tissues, but also persists throughout pregnancy. The rabbit, therefore, is a suitable animal in all respects for experimental work on the lines indicated.

In the chorion epithelium of several orders of mammals, including Man, we find, then, cells which are essentially malignant; but, insomuch as they are part of the normal mechanism whereby propagation is effected, natural inhibitory or cell-coördinating factors elaborated by the somatic cells of the embryo, restrain further development of, and invasion by, the undifferentiated epithelium. In this phenomenon we are permitted, I hold, to view a demonstration by Nature of the underlying mechanism that not only ensures cell coördination, but also brings recalcitrant embryonic cells into harmony with the rest of the organism. Have we not here presented the obverse of the chain of events that makes possible malignant neoplasia?

Since the fœtal secretion that inhibits the chorion epithelium could not be identified, it seemed to me that it might be worth while to study the action of some readily-available abortifacient. Eventually, I decided to investigate the properties of lead which, as is well known, may cause abortion. I soon came to the conclusion that the generally supposed modes of action—namely, the production of placental hæmorrhage and uterine muscular contractions—are not the primary causes. Hæmorrhage *from* the placental site is common to all cases of abortion, and if the ovum be expelled this must be effected by contractions of the uterine musculature. I see no reason to doubt—and I shall produce histological evidence in support of this view—that during the early stages of gestation lead circulating in the maternal blood acts directly on the embryonic cells of the chorion epithelium. We have found that in the later stages of pregnancy in the rabbit lead can be recovered from the fœtus itself.

I did not confine my attention to the action of lead on the chorion only; I investigated also the toxic effects of the metal on the gonads. The ovary showed no easily recognisable change—at any rate at first—but in the testis we observed the gradual disappearance of spermatozoa (Figs. 1 and 2). Since, then, lead has a selective action on certain tissues—sex cells, blood cells, nerve cells, and embryonic cells—there must be something common to all which attracts the metal. Now, the tissues mentioned are the very structures in which phosphatides—especially lecithin—are found in abundance; and the same chemical fact appears to be true of the embryonic cells of malignant growths.[3] Thus a substantial working hypothesis was evolved.

During the early stages of the work we used in our experiments ionic solutions and preparations which were partly colloidal, and we found a considerable difference in toxicity between the two. Fifty cases of cancer were treated in the period between November, 1920, and November, 1922, with encouraging results in a certain number. A preliminary discussion of this work was published last year.[4]

PRESENT ARRANGEMENTS FOR LABORATORY RESEARCH AND CLINICAL INVESTIGATION.

Although a considerable amount of laboratory and clinical work had been conducted, and scientific confirmation of our ideas and work had been obtained prior to February, 1923, it was then that a great step forward was taken. At the invitation of Vice-Chancellor Adami a few business men met, and most generously undertook to form with certain surgeons a committee to finance and conduct the business side of the work.* A large annual grant, has been placed at our disposal for a limited period. This generosity has enabled us to have twelve free beds set aside for cases of malignant disease. Moreover, the large staff shown in the following list has been enrolled to work out the different problems that have arisen.

Present Staff.

(December, 1923.)

Director: W. Blair Bell (H).

Chemistry.—Physical chemistry: W. C. McC. Lewis (P), J. Corran (W). Biochemistry: R. Coope (P), M. Jowett (W). General: J. Patterson (W).

Pharmacology and Toxicology.—W. J. Dilling (P)

Pathology.—E. E. Glynn (P), R. A. Hendry (P).

Animal Experiments.—H. E. Annett (P).

Clinical Work.—Surgery: H. F. Woolfenden (P), W. R. Williams (W). Anæsthetics: H. L. Patch (P). Special surgery: Throat and Ear, H. V. Forster (H); Eye, T. H. Bickerton (H); Radiography, R. E. Roberts (P); Medicine, John Hay (H).

Secretary: Edward Carey (P).

(H) = Honorary. (W) = Whole-time. (P) = Part-time.

In addition, there are two assistant secretaries and six whole-time laboratory assistants.

Regular meetings of the staff, or of the members concerned in some aspect or allied aspect of the subject, are held. Interim reports are issued from time to time from the different departments, and these are circulated. I need not deal further with the details of organisation; it is sufficient for me to state that the closest correlation and harmony exist, and that remarkable keenness prevails. It seems to us, indeed, that this coöperative system, in which experts in various branches of knowledge concentrate on the ramifications of a single issue, is an executive ideal too rarely realised. It has appealed, I know, to the great lay organisers on our committee.

In what follows it must be clearly recognised that most of the work accomplished has been concerned in clearing the ground, and, although almost entirely confirmatory of the original ideas and investigations, it must not be accepted as final. I shall give the general results now, and, at a later date, the different members of the staff will, it is hoped, publish in appropriate journals full accounts of the investigations with which they have been concerned. It is with the concurrence and assistance of the various members of the staff that I am able to present to-day this précis of our investigations in advance; and in doing so I would ask you to remember that only ten months have elapsed since the present organisation came into being.

GENERAL POISONOUS EFFECTS OF LEAD.

Since we are using lead therapeutically it has been a matter of the first importance that we should not only know the established facts about lead poisoning, but should also investigate certain points which have been doubtful or unknown. That lead is a poison need not be emphasised today; but it must not be supposed that this knowledge is recent. Galen, Aëtius, Palladius, Vitruvius, and Pliny, not to mention the compiler Paul of Ægina, were well acquainted with the ætiology and symptoms of lead poisoning. In 1767 Sir George Baker published an essay in which he traced the cause of "epidemial colic" in Devonshire to the use of lead in the construction of presses and cisterns for the preparation and storage of cyder. A century earlier it had been shown by German writers that the colic associated with the drinking of light wines was due to adulteration with litharge. In 1773 Thomas Houlston, physician to the Liverpool Royal Infirmary, published an essay on the Liverpool spa water, with "An appendix on the accidental use of lead." I am indebted to Mr. T. H. Bickerton for calling my attention to, and for lending me a copy of, this interesting pamphlet. I hope on some occasion in the near future to have the opportunity of dealing with the subject-matter of some of these early expositions.

The most commonly observed symptoms of lead poisoning, and those on which stress is laid in modern text-books of toxicology, are nervous lesions, intestinal colic, nephritis, anæmia, abortion and sterility. Our experience has taught us that the blood changes, with which I shall deal directly, are invariable, but that the avoidance of the more serious phases only is necessary with patients under treatment. Unfortunately, however, in the past we have observed encephalitis, optic atrophy, nephritis, heart block, and intestinal colic. The blue gum-line, not often seen in rabbits, and due, of course, to the formation of lead sulphide by the combination of lead with the sulphur in H_2S from decaying vegetable debris, has been of little practical service in the estimation of the degree of lead poisoning. We have been especially concerned in the study of differences in behaviour of ionic, partly ionic and partly colloidal, and completely colloidal preparations of lead. The physiological and toxic properties of each are being investigated, and the therapeutical dissimilarities noted. That these preparations do differ I shall exemplify presently. Clark[5] has recently drawn attention to, and righly condemned, the extravagant therapeutical claims made for "colloidal" preparations; but I have failed to discover in his writings any suggestion as to the probable mechanism whereby a *true colloidal* preparation may produce an effect.

EXPERIMENTS AND OBSERVATIONS CONCERNING THE TOXIC EFFECTS OF LEAD PREPARATIONS.

Dr. W. J. Dilling has been engaged in pharmacological—and, therefore, in certain physiological and toxicological—experiments concerning the action of lead on the heart, intestine, and uterus. These investigations are in an early or incomplete stage. It is possible that in dissimilar conditions and with solutions of different character and strength, other results may be obtained—results which will necessitate modifications and qualifications in respect of the following findings.

Heart.—1 c.cm. of a solution of lead acetate containing 10 per cent. of lead was injected into the peritoneal cavity of the frog, and continuous records were taken from the ventricle. The effects noted on the tracings were lowering of the tone and slowing of the rhythm due to prolongation of diastole and diminution of contractility. At the expiration of 45 minutes the heart muscle showed evidence of precipitation of albumin (lead albuminate)—a source of difficulty in regard to the interpretation of the action of lead on the tissues. At this stage the general tone was raised, the amplitude of contraction remaining constant for four minutes and then falling from weakening of systole. After 70 minutes a 2–1 heart block commenced. Subsequently there was a gradual slowing of the A.V. rhythm, without marked variation in tone or in amplitude of the ventricle, until the final stage when systole was diminished and cessation occurred in diastole. With slight variations the same phenomena were observed as the result of intraperitoneal injections of a preparation of lead iodide in a state partly colloidal, partly ionic. The interpretation of these results seems to be that the chief action of lead as a cardiac depressant lies in diminution of A.V. conductivity and in reduction of excitability of the rhythmogenic area. Dr. Dilling has made the very important observation that when the mechanism of the heart is deeply

* The members of the committee are: Mr. J. Arthur Smith (chairman), Mr. Rex Cohen (treasurer), Vice-Chancellor Adami, Colonel J. J. Shute, Mr. Crompton Wood, Mr. R. Wilson, Sir Robert Jones, Mr. F. T. Paul, with Mr. E. Carey as secretary.

affected by lead in the way indicated a weak solution of caffeine citrate restores the cardiac action to the normal. A preparation of lead in a completely colloidal state appears to have no action on the heart of the frog.

Intestine.—Experiments were conducted on the isolated intestine of the guineapig and rabbit. A piece of ileum was removed from a newly-killed animal and was suspended in Tyrode's nutrient medium at 38° C., and kept under a continuous stream of oxygen. So far the action of the partly colloidal, partly ionic preparation of lead iodide only has been tested. It was observed that instead of producing contractions lead causes relaxation and inhibition of peristalsis without interference with the vagus mechanism or the muscle. The action may, therefore, be located in the sympathetics or possibly in Auerbach's plexus. It is interesting to note that the actively-contracting intestinal muscle of the rabbit is more resistant to this effect than that of the guineapig.

Uterus.—Experiments were conducted on uterine muscle in the same circumstances and with the same material as in the case of intestinal muscle. It was found that the actively-contracting non-pregnant uterus of the guineapig is immediately inhibited. With a change of Tyrode's medium the contractions recommence. Similar results were obtained with the pregnant uterus. When uterine muscle contractions have been abolished by lead, adrenalin apparently has no effect; but pilocarpine produces characteristic tonic contractions.

Kidney.—Our clinical experience goes to show that after intravenous injections of saturnine preparations, lead may appear fairly early in the urine without any serious consequence following. The cessation of treatment leads to the disappearance of lead. If, however, the treatment be pushed, a fall in the daily quantity of urine excreted is noted, and this is usually associated with œdema of the ankles. A definite decrease in the amount of urine secreted is a grave danger sign; in animals—dogs under treatment for cancer, and experimental rabbits—anuria supervenes with cortical necrosis of the tubules (Fig. 3). It is interesting that with "lead nephritis" the amount of urine secreted may be decreased by one-half and contain an appreciable quantity of lead, without the appearance of albumin. This matter is under investigation. In the chronic form of lead nephritis the kidneys show interstitial fibrosis.

Blood.—The well-known basophil stippling together with hypochromasia and polychromasia of the red cells is of considerable diagnostic importance. The persistence of this phenomenon appears to be related to the natural tolerance of the individual and species of animal concerned: the variations are considerable. Men resist the toxic effects of this metal better than women, and adults than children; rabbits are much more immune than dogs and poultry.

The stippling usually commences at the periphery of the cell, but later may be found throughout; and, so far as we can judge, fine stipples precede the appearance of coarse. The nature of the stippling is unknown; some look upon it as a regenerative process, others as a degenerative. Whether we shall be able to solve the problem I do not know, but we have material enough for an extended study, which I hope may be seriously undertaken shortly. Poikilocytosis and anisocytosis are sometimes seen. The decrease in red cells and the increase in the mononuclear white cells are associated phenomena. Occasionally, nucleated erythrocytes appear at a late stage. Nevertheless, they may occur in young people without other evidence of poisoning. In figure 4 a general picture of the appearance of the blood cells is shown. Anæmia is the outcome of the disappearance of red cells and of the decrease in the hæmoglobin content so often to be observed. Moreover, we have reason to believe that the bone marrow itself may be attacked.

INFLUENCE OF LEAD ON NORMAL GROWTH.

I now come to a very important part of the subject, to which we have been alive from the commencement. I recall an occasion when discussing our work with Mr. F. T. Paul, whose wisdom in these matters is second to that of no one, he said "Can you arrest normal growth with lead? I have always believed that anything that is found to influence the growth of cancer will also influence normal cell-growth." I told him that I was even then conducting experiments on the subject.

Development of Hyacinth Bulbs.—Our first experiments concerned the growth of hyacinths, and these were carefully conducted on a large scale—about 100 bulbs were employed—by Mr. Patterson. The final results may be summarised as follows: The root growth—which, of course, precedes the floral development—was arrested in all cases in which the bulbs were in contact with solutions of normal or basic lead acetate in strengths varying from 1·0 to 0·000001 per cent. of lead (Fig. 5). In the stronger solutions the floral development, also, when it appeared, was stunted; but the weaker solutions (0·00001 and 0·000001 per cent. of lead), although arresting to some degree the root development, did not affect to any appreciable extent the growth of the leaves and flowers (Fig. 6). The white patches which appear in the photographs (Figs. 5 and 6) on the upper parts of the glass vessels containing 1·0 per cent. of lead acetate are due to deposits on the glass. Roots are absent except for one or two white root-spikes about one-eighth of an inch in length. Chemical examination by Mr. Patterson of bulbs some months after the flowers and leaves had withered revealed the presence of lead in them. It appears, then, that the root growth and, to a lesser extent, the floral development of hyacinths are arrested by solutions of lead acetate, and that the degree of arrest varies directly with the strength of the solution used. In this connexion a remarkably interesting observation has been made since this Address was delivered—namely, the bulbs, which were carefully dried and preserved after the flowers and leaves had withered last year (1923), when grown this year in unadulterated tap water present, so far as the root growth is concerned, exactly the same appearance as when grown in lead-adulterated water last year. We expect, therefore, again to observe stunting of the floral development when it appears from those bulbs which were immersed in solutions containing 1·0 per cent. of lead acetate last year.

Experiments conducted by Dr. Dilling in several directions have confirmed these findings.

Germination of Seeds.—The effect on germination of placing the seeds of mustard and cress on jute-covered corks floating on solutions of lead salts was tested. It was observed that solutions of lead acetate containing 0·1 per cent. of lead reduce the germination-rate by 20 per cent., but that the seeds which germinate subsequently grow well (Fig. 7). In the case of sunflower seeds it was, however, observed by Dr. Dilling that not only the rate of germination but also the subsequent growth of the plants was adversely affected. A solution containing 0·25 per cent. of lead reduces the germination rate 34 per cent. below that of the control, while the subsequent growth of the plant is slow and stunted. Solutions containing 0·5 per cent. of lead completely inhibit germination and growth.

Germination of Frogs' Eggs.—Next, investigations were conducted in regard to the effect of lead on the germination of frogs' eggs. Three females and one male were isolated in each of six single porcelain tanks. One lot was kept as a control. The water in the other five tanks was contaminated with lead in the proportions of 1–1000, 1–10,000, 1–20,000, 1–33,000 and 1–100,000 of lead acetate. In all cases copulation soon took place and eggs were deposited; the adult frogs were not obviously affected even after immersion for a period of three months. The eggs in the control tank germinated, but in none of the other tanks was

any change to be observed in the spawn. Further series of observations were made in regard to frogs' spawn laid in normal conditions. No germination occurred in the eggs when the spawn was placed in solutions of lead acetate similar in strength to those already mentioned. It appears, therefore, that solutions so weak as 1–100,000, if not weaker, will prevent the germination of frogs' eggs. Moreover, there was no evidence of the precipitation of lead albuminate in solutions in which the quantity of lead acetate was less than 1–20,000.

Growth of Tadpoles.—These experiments were continued by Dr. Dilling in regard to the growth of healthy tadpoles. Very young tadpoles with external gills were placed in fresh water containing lead acetate in the proportions of 1–1000, 1–5000, 1–10,000, 1–20,000, and 1–100,000. In all cases death resulted within 24 hours. A further series of experiments with more mature tadpoles with internal gills showed that *resistance to the poisonous effects of lead is directly related to the age of the tadpole* and that extremely weak solutions of lead acetate—that is, less than 1–100,000 which is the limit of safety—retard growth.* This action—namely, the arrest of growth—is well demonstrated by the use of partly colloidal solutions of lead. In figure 8 is shown the retardation of growth in the treated tadpole, in comparison with the control, by a partly colloidal preparation of lead iodide containing 0·2 per cent. of lead. I shall discuss the significance of these experiments on the inhibition of animal and vegetable germination and growth later. At the moment I would merely rivet attention on the fact that *the arrest of growth in animal and vegetable organisms is directly proportional to the capacity for, or power of, growth.* This, of course, implies a certain specificity of action. There is obviously a difference between the *killing* of tissues with the cessation of growth, and the *arrest* of growth in living organisms. Moreover, tissues appear to be permanently affected in respect of growth; for, although there be no evidence of continued lead poisoning, a child once poisoned remains stunted. Injured organs in the adult—unconnected with growth—show a definite tendency to complete recovery once the lead has been removed from the tissues in question.

There are, of course, many things that may influence germination and growth; heat and cold, electrical discharges, rays of various kinds, and chemical substances of different characters, such as acids and alkalis. Nevertheless, it must be borne in mind that a similar *effect* on growth does not necessarily signify a similarity of *action*, nor does similarity of action in this respect necessarily imply similarity of effect in the other conditions in which lead appears to have a specific action.

INFLUENCE OF LEAD ON THE CELLS CONCERNED IN THE IMPLANTATION OF THE OVUM.

I propose to discuss separately this important action of lead—a consideration of the possibility of which engaged my attention from the first, as I have already stated—for although, strictly speaking, the effect may be held to concern the arrest of the normal growth of embryonic cells, yet in this case we have to deal in part with the inhibition of undifferentiated cells rather than what may be called normal independent somatic development and growth of the living unit which I have just considered.

I shall, therefore, now deal with the abortifacient action of lead in those mammals in which actual invasion of the maternal tissues by the trophoblast of the ovum is seen. I have not been able to make comparative investigations with the ungulates, in which order of mammals there is apposition only of the chorion to the cotyledonary surfaces, because of laboratory limitations in regard to animals of so large a size. Yet, the action of lead on the ovum in the uterus of an ungulate would be interesting and informative, for we have always to decide whether abortion follows death of the embryo poisoned with lead, whether it be due to the action of lead on the chorionic epithelium, or whether both factors are concerned.

Although the abortifacient action of lead has long been known, careful studies of the site from which abortion has occurred are singularly few; indeed I know of no complete series of observations other than our own. Legge and Goadby [6] assert that "From what is stated later with regard to the curious action of lead upon the blood, the mechanism of abortion is easily understood; it is probable that placental hæmorrhages are produced as in other organs of the body." Oliver [7] states that "lead causes abortion probably by acting upon the unstriped muscular fibre of the womb and inducing spasm. The poison also passes from the blood of the mother through the placenta to the fœtus in utero, and by killing the fœtus it thus indirectly brings about abortion."

I have already exposed the obvious pitfall in regard to hæmorrhage *from* the placental site. I may also state that in our animals in which abortion occurred as the result of two or three intravenous injections of colloidal lead there was no hæmorrhage *in* the placental site or elsewhere, no stippling of the blood or any other evidence of lead poisoning. With regard to Sir Thomas Oliver's statement, Dr. Dilling has shown that preparations partly ionic, partly colloidal and containing 0·2 per cent. of lead, cause inhibition

* Owing to an oversight on my part the strengths of the ionic solutions used in the experiments concerning the germination of frogs' eggs and the growth of tadpoles were estimated in terms of lead acetate instead of lead, which constitutes 53·2 per cent. of lead acetate.

Descriptions of Illustrations on Special Plates.

FIG. 1.—Photomicrograph of a section of the testis of the normal rabbit. (× 250.)

FIG. 2.—Photomicrograph of a section of the testis of the rabbit after treatment with lead, showing the complete absence of spermatozoa and almost complete absence of spermatogonia. (× 250.)

FIG. 3.—Photomicrograph of section of the kidney of a dog poisoned by lead. There is necrosis of the cortical tubules. (× 62.)

FIG. 4.—Composite drawing to illustrate the changes that may be seen in the blood of a mammal poisoned by lead. Basophil stippling and nucleation of the erythrocytes is readily to be observed. There is also anisocytosis and poikilocytosis. (× 600.)

*FIG. 5.—Development of hyacinth bulbs, showing arrest of root growth resulting from contact with solutions of normal or basic lead acetate of various strengths.

*FIG. 6.—Development of hyacinth bulbs in contact with lead acetate solutions of various strengths. The root growth show graduated stunting, and in the strongest solution (1·0 per cent.) the floral development is also greatly arrested.

FIG. 9.—Section of the uterus of a rabbit, showing normal placental attachments on the tenth day after fertilisation. The dark area on the surface of the placental cotyledon marks the region of invasion by chorionic epithelium. (×3·3.)

FIG. 10.—Portion of the area of invasion of chorionic epithelium on the surface of the placental cotyledon under a higher magnification. (× 20.)

FIG. 11.—Section of the uterus of a rabbit which received three injections of colloidal lead (S_3) at intervals of two days from the eighth day after fertilisation. The placenta is clearly seen; and the white-ringed portion is shown under higher magnification in figure 12. (× 3·3.)

FIG. 12.—Portion of uterus and contents shown enclosed in white ring in figure 11. (× 25.) D, Indicates the wall of the uterus apart from the placental site. Large decidual cells are to be seen in the upper portion. M, Maternal mucosa. P, Placenta which is degenerated. No chorionic epithelial cells are to be seen.

FIG. 13.—Section of the uterus of a rabbit which aborted between the eighth and sixteenth day after fertilisation, stained by Weigert's method. Fibrin is shown *within* the vessels only; there is none in the surrounding tissues, as would have been the case if hæmorrhage had occurred. (× 8.)

FIG. 14.—Section of the uterus with placental site of a rabbit 11 days after coitus. Two doses of colloidal lead had been given at intervals of three days from the third day. No fœtal remnant appears in the section. (× 8.)

FIG. 15.—Section of the uterus of a rabbit on thirteenth day after fertilisation, the animal having received three doses of colloidal lead at intervals of three days, commencing on third day after coitus. The placental site has almost recovered from the chorionic invasion. (× 8.)

* The deposit of lead carbonate on the glass vessels containing the strongest solution (1·0 per cent.) unfortunately prevents proper observation of the absence of root growth. (See text.)

of stimulation, of uterine contractions. The possibility of abortion following death of the fœtus from lead poisoning cannot be contested: but in our opinion lead can only kill the fœtus secondarily, having first attacked the chorionic epithelium.

So long ago as 1911 I made a collection of sections from the pregnant uteri of rabbits on different dates of gestation in order that I might compare the normal histological anatomy with the abnormal condition produced by lead. To understand the normal histological phenomena associated with pregnancy in the rabbit and correctly to appreciate and appraise the various alterations in the maternal mucosa and the developments in the fœtal membranes and their epithelial coverings, is not an easy task; and it would have been considerably more difficult had we not had the advantage of being able to study the previous work of Duval,[8] Chipman,[9] and others. This is not the place to recapitulate our difficulties and observations of the normal processes of gestation in the rabbit. It is sufficient for me to say that the fœtal epithelium in the early stages of pregnancy is sometimes better appreciated in its absence after abortion than by its presence in the maternal tissues. Dr. Annett has conducted the animal injection experiments that have yielded for investigation by Dr. Hendry the material so important to our research.

It is interesting to note that in our early investigations when we used solutions of lead in ionic state the animals that aborted were always deeply poisoned. Other observers, also, have found that pregnant rabbits, which were made to consume lead with their food, invariably died after abortion from lead poisoning.[10] I have made a similar observation in connexion with the purposeful production of abortion in the human subject by the selfadministration of lead. In our more recent experiments, however,

7

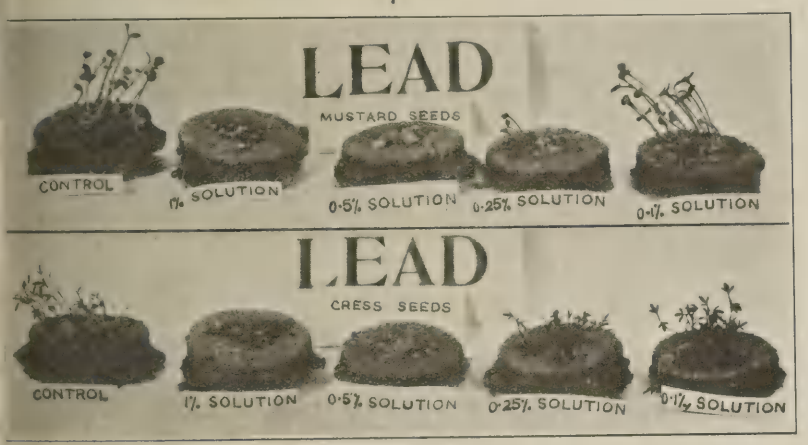

FIG. 7.—Effects produced on the germination of mustard and cress seeds and on the subsequent development of the plant when grown on jute-covered corks floating on lead acetate solutions of various strengths.

Dr. Annett has found, as already stated, that by using lead in a true colloidal state abortion alone may be specifically produced. Animals in which abortion has been produced are sterile subsequently for a limited time only. In figures 9 and 10 are shown uteri with normal placental attachments in the rabbit on the tenth day after fertilisation. The darkly staining epithelium of the chorion is clearly seen invading superficially the cotyledon in connexion with which the placenta is formed. Figure 11 is an illustration of the uterus of a rabbit, which received three injections of colloidal lead at intervals of two days, from the eighth day after coitus. The animal was killed on what should have been the sixteenth day of gestation. The placenta is clearly seen, but histological examination (Fig. 12) reveals the fact that the chorionic epithelium has disappeared and that what remains is a degenerating mass of tissue. The maternal vessels are thrombosed (Fig. 13), and there is no evidence of "hæmorrhage." In figure 14 the uterus and placental site of a rabbit 11 days after coitus are shown. Two doses of colloidal lead had been given at intervals of three days from the third day. No fœtal remnant is to be seen in the section.

8

FIG. 8.—Retardation of growth in the tadpole (left) when treated with a partly colloidal preparation of lead iodide containing 0·2 per cent. of lead. The tadpole on the right is the normal control.

The uterus on the thirteenth day after fertilisation, illustrated in figure 15, is from a rabbit which received three doses of colloidal lead at intervals of three days commencing on the third day after coitus. In this case the placental site has almost recovered from the chorionic invasion; indeed, were there not other evidence of pregnancy, such as the decidual reaction on the opposite wall of the uterus, it would, perhaps, be a little difficult to establish the existence of recent pregnancy. As I have already stated, the animals gave no hæmatological or other evidence of lead poisoning. We are endeavouring to obtain material at various short intervals after single doses of colloidal lead. In all our present specimens the chorionic epithelium had been completely destroyed. We want now to study the actual process of destruction.

Although many toxins produce abortion by affecting the fœtus itself, I am unaware of any chemical substance that has an abortifacient action similar to that of lead. Experiments are, however, now being conducted in order that such metals as thorium, copper, and zinc may be tested. At present we have no evidence, clinical or otherwise, which suggests that abortion may be caused by poisoning with metallic compounds other than lead. On the other hand, we have ample clinical evidence that mercury and calcium salts do not do so.

DISCUSSION OF EXPERIMENTS CONCERNING GROWTH.

I am now in a position briefly to discuss and correlate the essential points which have been elucidated by the foregoing experiments in relation to germination and growth.

Germination is the earliest demonstration of growth; therefore the inhibition by lead of this phenomenon, whether it be in regard to eggs or seeds, is a matter of considerable importance. Although the actual chemical mechanism of the phosphatide-growth relationship has not been demonstrated, it is certain that such a relationship exists, and that eggs, seeds, and young growing tissues are rich in similar phosphatides, even though in varying degrees. Maclean[11]

states that "Although no reliable method for the estimation of plant phosphatides has as yet been evolved, the results recorded by different observers indicate that the leguminosæ are relatively rich in this substance, the dried seeds containing up to 1·5 per cent. or more of phosphatides. On the other hand, cereals generally contain much less, the amount present being roughly about 0·5 per cent."

It is common knowledge that the yolk of eggs contains a very large quantity of the various associated phosphatides, and it is highly probable that the ovum itself is rich in these substances, although so far I have only been able to discover general statements on the subject. When, next, we turn our attention to the phosphatide content of young growing plants and animals we find that many investigations have been made; and this is especially the case in regard to vertebrates, in which we are, of course, chiefly interested. Glikin [12] has paid special attention to the subject, and has shown that a high percentage of lecithin is found in the bone marrow of the young of those species in which the offspring is feeble and helpless at birth. The same observer [13] has also found that the tissues of young animals are particularly rich in lipins, and that the phosphatide content decreases with age.

Now I have maintained the general hypothesis that in the adult lead exercises a toxic influence almost entirely on those special tissues that contain phosphatides in abundance. I have purposely excluded the kidneys and liver from consideration in this connexion, for, although rich in phosphatides, they are specially concerned in the elimination of lead from the organism, and therefore have a double selective action, as it were, on the metal; but of this there is no necessity to take advantage for the purpose of my argument.

It is, then, extremely interesting to know that lead is not only much more toxic to the young and pre-adolescent than to the adult and old throughout the vertebrate kingdom, but also that the *effects produced by the metal are general in the young and local in the adult*. When discussing the question of the affinity of lead for certain phosphatides with my colleagues and others, I have occasionally been asked why it is that lead, if it unites with phosphatides, does not attack equally every cell in the body; for it is generally stated that in all cells phospholipins are present.

The answer is contained in the aphorism I have just given concerning the different effects in the young and in the fully grown—that is to say, in the tadpole, as in the human infant, every cell in the body *is* affected; and, as the result, there is a condition of *somatic stunting*. It may be suggested that such an effect could be produced by the action of lead on the phosphatides of the anterior lobe of the pituitary, but while I cannot at the moment refute such an argument with positive evidence to the contrary, I may point out that this explanation cannot apply to plants. Moreover, whereas the growth of the tadpole is arrested and the animal poisoned by lead acetate in a solution no stronger than 1–100,000—we have not yet determined the minimal effective strength in regard to growth, but this is probably in the neighbourhood of 1–1,000,000—the adult frog is apparently unaffected by a solution containing lead acetate in the proportion of 1–1000. The tolerance of mammals, including Man, to lead likewise varies with the age of the creature concerned. What is the explanation? Why is it that in the young the effect is general and in the adult local?

Surely the reason is clear. In the young all the cells in the body are actively concerned in the processes of growth, and it is highly probable, therefore, that the phosphatides are in some more available form than is the case in the adult—if, indeed, the somatic tissues in general in middle and old age contain phosphatides in abundance. It seems reasonable to suppose, and this supposition is borne out by the related action of lead, that once somatic growth has ceased phospholipins only exist in an available form—physiologically and toxicologically, that is, chemically considered—in those tissues, the nervous, reproductive and the rest, of which I have spoken.

I need say but little more of the chorion epithelium—the most embryonic of all normal tissues of the developing ovum, the tissue of all others that grows with singular activity and invasive power, and which may become "malignant" in its neoplastic proclivities—for surely it is not difficult, in view of the experimental evidence I have already discussed, to understand the rapidity and certainty with which lead attacks the cells in question, nor to appreciate the fact that the effect produced is swifter and more certain in the early days of gestation than in the later phases, when the epithelium has lost its plastic, invasive, and destructive properties.

Abnormal Cell-growth.

It is often stated that there is no essential difference between innocent and malignant neoplasia, and in support of this belief it has been urged that it is sometimes difficult to distinguish histologically one from the other, that some growths are locally malignant—for example, ovarian papillomata—and that an innocent neoplasm may become malignant. There are, indeed, those who assert that the clinical history and outcome alone enable the surgeon to settle the question in certain cases, for instance, between a cellular fibromyoma of the uterus and spindle-celled sarcoma, and whether some papillomata be innocent or malignant. Even if we disregard such arguments as these because they refer to the subsequent course of events rather than to initial phenomena, it must be admitted that the primary metabolic factors associated with neoplasia are the same in both types—indeed, in all types of growth—and that the numerous inciting factors in abnormal growth—infection, trauma, and the like—are identical. It is only when we come to the question of somatic as opposed to chorion-like development that the real difference is observable; in the case of an innocent neoplasm hyperplasia occurs, in a malignant dedifferentiated growth supervenes.

I wish to lay some stress on the similarity of the intrinsic metabolic factors concerned in all forms of growth—whether there be somatic differentiation or dedifferentiation—for on this fact the explanation of all our work on cell growth depends. As I have already mentioned, it has been shown by Bullock and Cramer that, in common with all other actively-growing cells, the phosphatide content of malignant tumours varies directly with the rate of growth: the more rapid the growth of the tumour the greater the quantity of phosphatides present.

Effect of Lead on Abnormal Cell-growth.

If it could be shown that the action of lead is also proportional in its degree of toxicity to the rate and power of growth of malignant tumours, as it is in the case of normal growth, then a complete case would have been made out for the treatment of every malignant growth with preparations of this metal. Unfortunately, the proof is not so readily obtainable as we would wish. Nevertheless, Mr. Patterson has found that in dogs which suffered with cancer and died from lead poisoning, this metal is concentrated in by far the largest proportion in the neoplasm and the testes. He has also found lead in disproportionate quantities in tumours from patients treated with this metal before operation. Why, then, it will be asked, is there any difficulty in treatment? Let me explain.

In our experiments, it will be observed, the growing tissues concerned could not escape from the influence of the metal. It is not possible, however, in cases of malignant disease to make sure that sufficient lead reaches the actively-growing cells; this is, of course, more evident in regard to carcinomata than sarcomata which possess a good blood supply. Moreover, to damage only the cells of the neoplasm and to leave uninjured those of other parts of the organism which may have an attraction for lead is a formidable

proposition. These two difficulties are, without doubt, difficulties of the first order. So far they have not entirely yielded to our attack, although I think the early recognition of them, before the treatment of patients commenced, has led to results that we could not have obtained had we simply administered lead. For the most part patients with malignant disease are adults; consequently there is no "loss" of lead to the normal growing tissues. We are concerned, therefore, in endeavouring to reach the neoplasm without injuring the vital organs which also attract lead.

Now, we have proved that not only in dogs with cancer, but also in the case of the adult human subject suffering with this disease, lead is recoverable from the growth in a quantity out of proportion to that contained in any other part of the body, excepting only the gonads; consequently we may say that lead is attracted to the growth in preference to other tissues, and probably this is so for the reasons I have given. Yet, it still remains true that we cannot be satisfied with the fact that the new growth is capable of holding a large proportion of the lead stored in the body; its powers of attraction unaided may not be great enough for the neoplasm to take from the blood stream sufficient lead entirely to arrest further development. From the first this difficulty presented itself, and seeking to overcome it we endeavoured to find something for which growing tissues have a special preference, possibly not possessed to the same extent, if at all, by the vital organs that show an affinity for lead. The only substance that readily came to mind was thyroiodin, so we have used this in combination with lead in the hope of getting the metal taken up, as it were, by false pretences.

Moreover, we have long considered, and are now trying, a method whereby we hope to "lock" the metal in the neoplastic tissues by means of calcium salts administered intravenously in a colloidal form after the patient has received as much lead as he or she can tolerate. Calcium salts reduce, as is well known, the permeability of the cell membrane. I am glad to say that Prof. Lewis and his collaborators have succeeded in making a very stable calcium colloid that stands boiling and is innocuous to the organism when introduced into the blood stream.

PATHOLOGICAL INVESTIGATIONS.

We have never hoped to obtain on *ordinary* histological examination evidence of a specific change in carcinomata due to treatment with lead. The fact that cancer is a more or less chronic disease and one in which the lesions undergo necrotic and fibrotic changes in the natural course of events, precludes the inclusion of such changes as specific to lead, although we know that similar changes may be produced by this metal in the liver and kidneys. In only one case, in which a rapid cure was effected, was there evidence of unusual appearances. We have not had an opportunity of examining sarcomata before and after treatment except in one case which did not recover.

My colleague, Prof. Glynn, aptly summarises the position in the following statement:—

"All these considerations suggest that *easily recognisable* histological changes in cancerous tissue, produced by lead treatment, will be *slight and non-specific* and will probably resemble those often found in untreated cancer. One would also expect that regressive changes would be more marked at the periphery of the cancer where the vessels and lymphatics are presumably normal.

The examination of all the available sections confirms these suppositions. . . . No marked regressive changes have been noted and certainly no specific changes.

Nevertheless, there is on the whole more retrogression in the treated than in the untreated. This is particularly recognisable by the diminution in the number of epithelial cells and an increase in the amount of stroma. These changes are often associated with distortion, atrophy, œdema, or mucoid change of certain groups of epithelial cells."

I hope when fat stains have been used that we may be able to note some specific change in regard to the lipin content of the cancer cell before and after treatment.

CHEMICAL INVESTIGATIONS AND CONSIDERATIONS.

Lead and the Phosphatides.—It will be wondered whether we have any chemical evidence to support certain explanations I have given, particularly in regard to the way in which lead inhibits growth. Whether this metal has an affinity for phosphatides that can be demonstrated on the bench of a laboratory. As I have already implied, the selective action of any toxic substance must depend on chemical affinity between the toxic body and some element or elements in the tissues affected. I use the term "chemical affinity" in the widest sense to include manifestations ascribed to the processes associated with physical chemistry. There is, however, a tendency today to look upon all phenomena, even adsorption, with a stoichiometrical eye.

In quite the early stages of the investigation we had found that an emulsion of *commercial* lecithin is immediately precipitated by ionic solutions of lead acetate; and that zinc and copper acetates have relatively less effect in this respect. With regard to the phosphatides it must be remembered that they, or at any rate those of which we have any substantial knowledge, are all associated in the tissues, and that it is only with considerable difficulty that they can be separated and obtained chemically pure. The different solubilities in alcohol of lecithin, kephalin, and sphingomyelin are of assistance in differentiating one from another. Prof. Lewis has found that both commercial and pure lecithin in water have negative charges as demonstrated by the cataphoresis method. This, of course, is of importance in regard to the question of combination with cations, such as lead. Experiments were also conducted with various metallic salts in relation to pure and commercial lecithin, and pure kephalin and sphingomyelin. It was found that whereas divalent cations precipitate both kephalin and sphingomyelin, lecithin, when pure, is not precipitated either by lead ion or lead suspensoid, or, indeed, by any divalent cation. Since there is total precipitation by lead ion of the commercial lecithin emulsion, which contains all three phosphatides, it would seem that lecithin is carried down by the lead kephalin and lead sphingomyelin precipitates. Cholesterol appears to favour this reaction, presumably by increasing the degree of dispersion of the commercial lecithin emulsion.

The fact that pure lecithin is not precipitated by lead does not by any means prove that there is absence of chemical combination between them. In one of the interim reports by Prof. Lewis and Dr. Corran is the following discussion of their investigations into this question:—

"From the above experiments on precipitations of commercial lecithin emulsions by lead suspensions, it would appear that absence of precipitation does not necessarily denote absence of chemical combination. In fact, experience tends to point to the conclusion that precipitation in such cases is purely an adsorption phenomenon. For example, on the addition of a calcium salt to commercial lecithin, a ppt. is obtained. On attempting to wash this ppt. it apparently re-emulsifies. This suggests that the precipitation is caused by the adsorption of calcium ions, and when the latter are removed by washing the lecithin reverts to the emulsion form. Work is at present being carried out to decide whether this ppt. with calcium is a chemical or an adsorption compound.

In the case of lead ion, which apparently forms a definite compound with at least one of the constituents of commercial lecithin, precipitation would not occur, according to the above considerations, until there was excess lead ion above that required to form the chemical compound. The observation has been made that, on attempting to wash the ppt. formed by the addition of lead acetate to commercial lecithin emulsions, there is a great tendency to re-emulsify. Thus, in the case of Levene's pure lecithin, although neither lead ion nor lead suspensions caused precipitation, it was quite possible that the resulting emulsion consisted of a combination of lead and lecithin. Unfortunately, the resulting emulsion in this case was not tested to see if the lead was in combination with the lecithin, since it was to decide whether or not lead ion actually precipitated pure lecithin that the experiment was primarily performed."

It is unfortunate that the difficulty of separating lecithin from kephalin and sphingomyelin is considerable, and that we have been able to procure—and this we owe to the kindness of Dr. Levene, of the Rockefeller Institute—only a small quantity of pure lecithin. Nevertheless, since lecithin is so closely associated with the other phosphatides in the tissues, and resembles, in fact, commercial lecithin in this respect rather than pure lecithin, it is hardly possible that it would remain unaffected if the other phospholipins were combined with lead. The interesting observation has been made in the Physical Chemistry Department that the percentage of lead in the lead-lecithin (commercial) compound is between 11 and 12 per cent.

Although I have suggested that the rôle played by lead in the phenomenon of arrested growth depends on a direct chemical reaction between lead ion and phosphatides, we must not overlook the possibility that lead may act in other ways; for example, by the inhibition of enzyme action in relation to growth. The distinction between these effects, however, may not be so great as appears at first sight, since such a function of lecithin as, for instance, that of an oxygen carrier, might indirectly affect enzyme action.

Experiments Concerning Hydrogen-ion Concentration.—The hydrogen-ion concentration has often been taken into account in explanations of the effects of solutions on either side of neutrality, which are believed to exercise a beneficial or detrimental influence on normal growth. Prof. Lewis and his colleagues have devoted much time to the study of the hydrogen-ion concentrations in the various preparations that have been used experimentally and therapeutically for the arrest of normal and abnormal cell-growth. This has been considered a matter of some importance, not only in connexion with the views that have been expressed concerning the influence of acid and alkaline solutions on, for instance, sea urchin's eggs,[14] but also in regard to the effect that might be produced by tissues—normal and abnormal—on the preparations injected into the blood stream. In the first place, it was found that the pH of lead suspensions could not be accurately measured by means of the usual hydrogen electrode, owing to the fact that there is a chemical reaction between the hydrogen and the lead suspension, and this causes the hydrogen electrode to register an oxidation potential. The Biilmann quinhydrone electrode [15] was therefore tested with solutions of known pH and found accurate. It was again observed, however, that the results with lead suspensions were neither uniform nor correct. It was accordingly decided to try a gold terminal instead of one made of platinum, for it was thought that the platinum was acting as a catalyst. We had no knowledge at that time that gold had been used quite recently for a somewhat similar purpose in Gowland Hopkins' laboratory. With the adoption of a gold terminal satisfactory results were obtained with the Biilmann quinhydrone electrode. I do not think it necessary at this stage to say more than that the suspensions of lead prepared by Prof. Lewis have a pH of 10·9 when the lead content is 0·25 per cent., and a pH of 10·3 when 0·1 per cent.—both distinctly on the alkaline side. An examination of a partly ionic, partly colloidal, preparation of lead iodide made by Mr. Patterson revealed a pH of 5·5, which is on the acid side of neutrality. It now remains for the pH of malignant tumours in situ to be estimated and compared with that of the normal tissues of the same patient.

Functions of Cholesterol and Lecithin in Cell membranes.—Another matter of great biochemical interest has been investigated by the same workers: namely, the function of cholesterol in cell membranes, and the effect of lecithin on oil-water interfacial tension. According to physicochemical theory any substance which is soluble in oil and at the same time lowers the interfacial tension between oil and water will favour the formation of a water-dispersed-in-oil type of emulsion. It was found that cholesterol and calcium chloride have a similar action in that they decrease the interfacial tension between oil—olive and cotton-seed oil were used—and water. Calcium soap has long been known to be more "soluble" on the oil side of the interface, and cholesterol is soluble throughout the bulk of the oil to which reference has been made; consequently cholesterol and calcium favour the formation of the water-dispersed-in-oil type of emulsion, of which butter is an example. As cotton-seed oil and olive oil were employed in the experiments it is not possible to do more than surmise that the cell membrane, which is believed normally to consist of a water-dispersed-in-oil system is similarly affected. Lecithin appears to have an influence exactly opposite to that of cholesterol: that is to say lecithin favours an oil-dispersed-in-water emulsion an example of such a system being cream.

The practical suggestion arising from this work is that in carcinoma, in which the proportion of lecithin to cholesterol has been found to be higher than in normal tissues,[16] the cell membrane will be less stable owing to the fact that it probably exists as an oil-dispersed-in-water, in contrast with the normal water-dispersed-in-oil, type of emulsion, with increased permeability of the cell covering.

Action of Lead on Enzymes.—Dr. Coope and Dr. Jowett have commenced a series of investigations concerning the effect of lead on enzyme action, and these workers have issued an interim report. The results, however, have proved difficult of correlation and interpretation. Nevertheless, it appears that lead has a definite retarding effect on tryptic digestion. It is, however, quite impossible to say at present whether lead influences the enzymes that may be concerned in cell growth. The work is to be prosecuted on new and more extended lines.

Preparation of Lead Suspensions.—The great advantage of utilising lead suspended in a colloidal form is obvious. It is lead ion that produces the poisonous and probably the therapeutical effects: but owing to the highly toxic action of large amounts of lead ion it is not advisable to use it therapeutically by intravenous injection; at least, if we do, we are using a preparation that is uncontrollable and highly dangerous. A large amount of work has, therefore, been conducted in an attempt to secure a reliable and *stable* preparation of lead suspension. In regard to complete stability—stability of more than a few days' duration—we have failed. First, we employed lead iodide suspended in gelatin. It occurred to us to use thyroiodin as our source of iodine, and to employ a calcium salt to increase the stability of the suspension by decreasing, as I thought, the power of what is generally called "imbibition" on the part of the gelatin coverings of the suspended particles. This suspension was prepared by Mr. Patterson. Prof. Lewis, however, attributes the action of calcium in this respect to electrical protection of the ordinary kind resulting from adsorption of the divalent calcium ions on the colloid. Whether the calcium likewise affects the adjacent layer of gelatin in the sense of "hardening" he thinks uncertain. Subsequently, it was proved that the lead iodide preparation is only partly colloidal, and that it always contains, as we had suspected, lead ion in considerable quantity.

Next, much work was done in the Muspratt Laboratories in regard to lead suspensions made by the electrical method of Bredig. By the use of calcium increased stability was secured and in a summarising interim report Prof. Lewis and his colleagues state:—

"We conclude, therefore, that calcium ion is an indispensable adjunct for the preparation of stable suspensions of lead. It was also observed that the addition of isoelectric gelatin further increases the efficiency of the protective action of calcium ion on lead suspension."

Weak acids immediately convert this colloidal suspension of lead into lead ion. Yet, although the suspension can be boiled and will remain stable for perhaps three days, so far we have failed to produce a preparation which can be generally utilised.

Another initial difficulty which has been easily surmounted was the large size of many of the particles of lead in the electrically-prepared suspension. These, however, can be thrown out by centrifugalisation, those remaining being no larger than 0·3 μ in diameter.

I have spoken of lead ion as being active, and of truly colloidal lead as inert; but it is certain that suspensions are disturbed, and lead ion slowly produced in the blood stream, and rapidly in any part of the body in which the hydrogen-ion concentration is high, such as would obtain in a tumour undergoing autolysis. As I have said, we have not yet, but hope soon to have, information concerning the hydrogen-ion concentration in actively growing neoplasms in which there is no degeneration.

The very numerous and arduous experiments conducted in the Muspratt laboratories, which will, I hope, be published eventually, may throw light on much beyond that with which we are immediately concerned.

In concluding this summary of the chemical investigations, I may say that our chief difficulties now lie, not so much in justifying the original ideas concerning the action of lead on growth, for that has been made evident, even though the complete chemical mechanism may require further elucidation, as in applying them to the treatment of malignant disease. This has always been the case in the treatment of tropical diseases, syphilis, or any other malady that has long resisted curative therapy.

Here we are faced, in the first place, with the problem of introducing lead into the blood stream in an inert state, and, although growing tissues have themselves an attraction for this metal, of getting it in sufficient quantities into the new growth alone. In the second place, even though we get lead into the tumour, can we ensure that it stays there and produces the effect required? I have endeavoured to relate the means we have adopted, and are adopting, to get over these apparently insuperable obstacles to successful treatment.

CLINICAL WORK.

It has been a source of pleasure to me to learn from some of my fellow-members of the Society that they are more interested in the scientific aspect of the subject, which I have just endeavoured to expound, than in the purely clinical, for they wisely realise that at first, at any rate, there are and must be the difficulties of which I have spoken, and that patience, time, and energy alone can overcome them. In acknowledgment of this thoughtful point of view, and because a number of patients, believed to be cured of sarcoma and carcinoma, presented themselves for inspection and examination before the Address, I shall deal very briefly with our clinical work.

Methods of Treatment.

Intravenous Injection.—It is almost certain that the ultimate mode of treatment in malignant disease will be by the blood stream. Wonderful as may be the results of operation, and of applications of X rays and radium, the field of action, so far as these procedures are concerned, is a local one. Moreover, even though the growth be quite local, there are many cases in which it is beyond the reach of such methods of treatment. There are, too, numerous instances in which metastases are present in inaccessible organs. All this is recognised by the thoughtful surgeon. It is, however, well that the limitation of local treatment should be repeatedly emphasised, lest too great a sense of contentment obstruct our view of better things. In three years (Nov. 9th, 1920 to Nov. 9th, 1923) 1531 intravenous injections were given, chiefly by Mr. Woolfenden. At first we used only partly colloidal lead iodide preparations of which many variations have been made; when this preparation is now employed, we inject what is known as A_1 A_2 prepared as soon as possible before injection. As this can be kept in two solutions, it might be generally used were it entirely satisfactory; but it is not, for it is only partly colloidal in nature, and therefore toxic. The electrically prepared colloid made in the Muspratt laboratories appears to be satisfactory in respect of its atoxicity. We believe that lead ion is slowly liberated from the colloidal solution in the blood, and thus a more or less continuous small dosage of lead ion is administered.† The preparation now in use is known as S_3.

Intramuscular Injection.—It is sometimes extraordinarily difficult, in fat women, to give an intravenous injection however skilful the operator may be. We have never been defeated in the end, but it is possible that some day we may be. We have, therefore, given thought to the question of intramuscular injection in such circumstances; and Mr. Patterson has prepared for the purpose a combination—as we believe—of lead and cod-liver oil. Our animal experiments with this material, although they have not been pushed to a final conclusion, indicate that such a preparation is not very readily absorbed. In any case, intramuscular injection will never be a method of choice.

Ionisation.—A third method of administration has been utilised—namely, ionisation. We have found that this method of treatment is only useful when the patient has been poisoned with intravenous injections, and no more are justifiable for the time being. Although we have not observed much change in a superficial growth, pain appears often to be relieved. The type of case in which we have employed ionisation has been that in which there are hard avascular secondary skin nodules or secondary deposits in the sternum. On the other hand, Dr. Annett has treated three rats with large malignant tumours,‡ and in every case the tumour has entirely disappeared. Borrel [17] has obtained somewhat similar results with lead ionisation of rat tumours. In contradistinction, a case of cancer of the scrotum of a dog did not appear clinically to be altered by this method of treatment.

Lead and X Rays.—We have seen several very striking instances in which tumours in patients first treated with lead without the disappearance of the growth subsequently exhibited striking retrogression after applications of X rays. In some cases X ray treatment had had no effect previously to treatment with lead. The beneficial effect, or perhaps I should say augmented effect, of X rays in these cases is probably due to secondary radiations produced by the lead in the tumours. Dr. Roberts has in hand some experimental work on this subject.

Immediate and Remote Effects of Injections.

These effects are local and general. Formerly there was considerable general disturbance after an intravenous injection, vomiting, rigors, and rise of temperature being usual concomitants. Now, however, if the improved material be warm and the injection of it be slow, a general reaction is rare. In carcinoma, œdema around the lesion is frequently observed after a few injections. Sometimes with sarcomata a considerable local reaction is produced after about the third dose. If the tumour be near the surface, the skin over it becomes tense and red, and a slight general febrile reaction may supervene. In a large majority of all cases, whatever the nature of the neoplasm may be, the patients complain of *pain in the growth between two to eight hours after injection.* Our attention has repeatedly been called by the nurses in charge to this suggestive phenomenon.

Interesting as are the immediate results of the administration of lead, it is in the remote effects that we are chiefly interested. The local alteration in large, hard, carcinomatous tumours, when this is observed to be following a satisfactory course, consists of a definite lobulation of the surface, as though the mass were breaking up into separate smaller tumours.

† I have long held the view that calcium ion in the blood has its source of origin in the [illegible] so-called "combined" or "masked"—calcium.

‡ Annett, H. E.: Rat Sarcoma, for which we are indebted to Dr. J. A. Murray, of the Imperial Cancer Research of the Royal College of Physicians and Surgeons, London.

At this juncture such cases should be subjected to X rays. Sarcomata may soften and liquefy, giving rise to serious complications; or, after the preliminary reaction, which is probably due to gradual liquefaction, they may be absorbed. Many patients who are improving under treatment accumulate fat rapidly. Whether this is due to a general improvement in their condition or to an action of lead on the lipins of the pituitary it is not at present possible to say. The remote general disturbances consist, of course, of the symptoms of lead poisoning to which I need not further refer. In a few cases we have used intramine, which is supposed to have the faculty of assisting in the elimination of the heavy metals, but I do not think we have observed any definite beneficial result follow the administration of this substance.

At this point I would emphasise the fact that lead poisoning in its grave forms is a very real danger. Yet, with increased experience in the estimation of the value of the changes in the blood and urine, in the interpretation of symptoms, and, above all, in the spacing of the doses according to the nature of the neoplasm and the individual tolerance of the patient, we now feel that the dangers to which the patients previously were exposed have been considerably lessened.

Types of Cases Treated.

From a summary of the cases treated I find that there is not a single early case. Some have been operable in the sense that we ourselves have operated usually in order to reduce or remove the mass of growth; and it is possible that one or two of the operations cured the patients. There is none, however, in which a favourable prognosis could have been given. In most the outlook has been hopeless. Two-thirds (81) of the total number of cases have been primary and one-third (41) secondary in origin. In many in which the disease was primary there were metastases. The following is a list of the sites of the primary lesions in our cases.

Carcinoma.—Mammæ, cervix uteri, rectum and colon, stomach, pancreas, œsophagus, tongue, tonsils, pharynx, superior maxilla, ovaries, parotid, kidney, mediastinum, glands of the neck, vulva and vagina.

Sarcoma.—Femur, humerus, scapula, sacrum, superior maxilla, small intestine, and (?) generalised involvement of abdominal lymphatic glands.

The results are summarised in the table below.

After-histories of Patients treated with Lead between Nov. 9th, 1920, and Nov. 9th, 1923.

Received intravenous injections	122
Alive and believed cured	19
Disease arrested or retarded over periods between one and three years	6
Under treatment and improving	6
Under treatment for too short a time for an opinion to be formed	7
Disease arrested, but patient died of intercurrent affection	1
Died from malignant or intercurrent disease shortly after treatment commenced	20
Have shown some improvement, but have subsequently died	13
Alive, but are not improving	2
Commenced treatment which was discontinued either because they were too ill or at their own request	18
Died from malignant disease without showing improvement	30

I do not propose to dwell on these statistics, for all statistics—like emulsions—are notably reversible. If I were to do so I might be tempted to remove from consideration those cases which died within a few weeks of being seen for the first time, those that died of intercurrent affections, those in which treatment was stopped, and those which have not been treated long enough for an opinion to be formed. I should then be left with a very satisfactory percentage of what we are content to call "believed cured." Time, however, is a factor that plays its part in the final estimation of results.

Discussion of the Clinical Work.

If I may draw provisional and conservative conclusions from our clinical work, which has been done on a fairly large scale, I must call attention in the first place to the fact that a large proportion of the material which we have received for treatment was totally unsuitable for any treatment—the cases were actually dying. Dr. William Mayo, who saw with me some of the worst cases then under treatment, said in his incisive way, "Surely you are expecting miracles, not cures." I am glad to say that so far his prognostications have not proved entirely correct and I think he would be interested to know that some of the cases are still alive and are better than when he saw them, if not well. Nevertheless, this great surgeon was right in one sense; the strain of having to expect "miraculous" happenings or death is not good for the mind or body of the surgeon.

In the second place, I would say that patients in good condition in whom the growth is inoperable, whether it be primary or secondary, should have the opportunity of treatment. There is nothing else that offers any hope. When the case is operable, I believe that the tumour should be removed and the patient treated immediately after operation to prevent recurrence. Serious radical operations with a large primary mortality—such as the extensive Wertheim operation for carcinoma of the cervix—may possibly be avoided if the patient can be treated after operation. Vaginal hysterectomy, for instance, even when the growth has not been entirely removed, has given encouraging results when intravenous injections of lead have subsequently been administered. Lastly it is safe to say, that the combined treatment, first with lead and subsequently with X rays, should be tried for all inoperable but accessible growths. Possibly ionisation followed by applications of X rays may be advisable in certain cases.

With regard to the future of the work I can say this: in the treatment of cancer there never can be a cure for all the dying cases we have seen—there is in some as much abnormal tissue as normal. I firmly believe that we are on the right—perhaps I should say "the best"—line of investigation and treatment. It is indeed, to my imperfect comprehension the only truly scientific path along which further advance can be made.

That we use lead is, perhaps, a confession of weakness; for, to return to my original hypothesis, when we have isolated or synthesised the biological substance—the somatic tissue secretion that controls the chorionic epithelium and cell correlation, for which I sought in vain—when we have done this we shall have, at least theoretically, a true specific. Meanwhile, we use lead, for it fulfils the experimental and often the clinical, demands made of it. I do not deny that there may be other substances that will do all that lead can do in regard to growth and be less toxic in other respects. All these considerations are included in our scheme of work.

In conclusion, I must acknowledge the generosity of our friends the members of the Cancer Research Committee, and the ability and cordial coöperation of my colleagues who have enabled the investigations to be prosecuted in so thorough and scientific a manner. I fear this presentation of the work has fallen far short of what is due to these endeavours.

LEPROSY, A SELF-HEALING DISEASE.[1]

BY ERNEST MUIR, M.D., F.R.C.S. EDIN.,
RESEARCH WORKER IN LEPROSY UNDER THE INDIAN RESEARCH FUND ASSOCIATION, SCHOOL OF TROPICAL MEDICINE AND HYGIENE, CALCUTTA.

Hansen[1] and others have stated that leprosy shows a tendency to spontaneous recovery in many cases; but the significance of this fact does not seem, as far as I am aware, to have been realised by modern writers on leprosy.

Immunity.

If we compare leprosy with the well-known self-healing diseases, such as lobar pneumonia, enteric, or small-pox, we notice a great difference in the course of leprosy as compared with these diseases. In the latter we have a short incubation period, a rapid onset and rise to a climax when immunity has become sufficient to cause more or less rapid diminution and disappearance of the disease, the whole course being finished within a comparatively few days. The object of this paper is to show that there is a similar process in leprosy, only that what happens in a few days in small-pox and enteric happens in as many years in leprosy. The length of time taken by leprosy to pass through all its stages (sometimes a whole life-time, though it is often much less) has obscured this fact regarding the nature of leprosy. Yet, as Newton learned much about the properties of the earth from a falling apple, so we may learn much about leprosy, the "king of diseases," from these short-lived fevers.

Leprosy resembles tuberculosis in many respects. In both diseases the bacillus is acid-fast. This property of acid-fastness is apparently due to some lipoid substance contained in the bacilli which directly or indirectly prevents the quick formation of immune bodies such as are formed in rapidly self-healing diseases. For this reason neither leprosy nor tuberculosis is a rapidly self-healing disease, although in both of them there is a slower and more gradual production of immunity.

While this is the chief point of resemblance between leprosy and tuberculosis, an important point of difference lies in the fact that, while tubercle attacks vital organs, leprosy confines itself almost entirely to the skin, mucous membrane, and peripheral nerves.* Thus, while tubercle is a fatal disease, leprosy is a disease of disfigurement and disablement and is seldom directly fatal except in the more active forms of the nodular type. The death of leprous patients is generally the result of complications many of which are preventable, or it is due to the inability of the patient to get work or to do work which will maintain him in the necessities of life.

A well-nourished leper may have nearly the whole surface of his body covered with skin every cubic millimetre of which contains billions of lepra bacilli and yet he may maintain comparatively good health, being able to work strenuously 12 hours a day and carry on a large business. No tuberculous patient harbouring even a far smaller number of tubercle bacilli could be expected to live for long. Thus, in tuberculosis, while there is a slow immunity-producing process present, death supervenes before sufficient immunity can be induced to cause self-healing of the disease; whereas in leprosy, which is seldom of itself a fatal disease, spontaneous recovery frequently takes place. The course of a typical case of leprosy may be indicated by a rising and falling curve, the summit of which denotes the point at which sufficient immunity has been induced to cause the gradual elimination of the disease from the body.

The course of leprosy may be conveniently divided into three stages. In the first, which corresponds with the beginning of the curve, the bacilli are few in number, the lesions are not widespread, and immunity is low. In the second stage, which corresponds with the rise of the curve, the bacilli have multiplied, but immunity is still low. In the third stage, which corresponds with the descent of the curve, lesions are widespread, but show signs of resolution and disappearance. Immunity has increased to such a degree that self-healing has begun to take place.

It is highly important to be able to recognise what stage of the disease a patient has reached. This can only be done with any certainty by the clinical appearance of the lesions. In cases in which there are widespread lesions, especially if these are lesions of the skin type and not of the nerve type, and if these lesions appear to be resolving, becoming less erythematous and swollen and presenting the typical appearance of resolved lesions, then it is not difficult to conclude that the patient has reached the third stage. I have described the appearances of such lesions more fully elsewhere.[3] [4] The recognition of the stage in leprosy is of vital importance both in the prognosis and the treatment.

General Resistance of the Tissues.

This must be clearly distinguished from acquired immunity. Various attempts have been made to inoculate leprosy on experimental animals, but, as far as I can judge, none of these attempts have as yet been successful. This is undoubtedly because the resistance of the tissues in these animals is too strong to allow of the bacilli multiplying and forming lesions. In other words, the tissues of these animals do not form a suitable soil for the growth of the leprosy germ. Various attempts have also been made to inoculate lepra bacilli on man. With one possible exception these also have failed, the reason probably being the same—viz., the general resistance of the tissues was too strong in these individuals so that they did not form a congenial soil for the growth of the lepra bacillus.

The onset of leprosy is almost invariably associated with the lowering of this general resistance in some way or other. The first signs of the disease frequently occur during or after some acute disease which has temporarily lowered the resistance, and these signs not infrequently subside once more as resistance is restored after recovery from the acute disease. This subsiding and disappearance of lesions must be clearly distinguished from the similar process which takes place in the third stage of leprosy due to the production of immunity. In the former case we have a restoration of the natural general resistance of the tissues which had been temporarily lowered; in the latter we have the formation of antibodies and the acquiring of special immunity to leprosy.

When, however, the onset of leprosy is associated with the lowering of the general resistance due to some cause which is neither temporary nor self-healing, leprosy continues to make headway in the tissues of the body until such time as one of three things occur: (*a*) The general resistance is restored, (*b*) the patient passes into the third stage and the disease becomes self-cured, or (*c*) the patient dies of some complication or of some other cause. Chief among such causes of prolonged lowered resistance may be named chronic bowel diseases, syphilis, and other chronic diseases, unsuitable diet, unfavourable climatic, sanitary, or economic conditions.

The Phases of Leprosy.

In acute infectious diseases the multiplication of the causal organisms is synchronous with acute toxic symptoms, toxins being set free by the bacilli as they multiply and in proportion to their numbers. In leprosy, however, the multiplication of bacilli may go on rapidly with but few toxic symptoms, and, as is mentioned above, huge numbers of bacilli may be present in the skin while the patient retains comparatively good health (Fig. 1). On the other hand,

* It is true that in fairly advanced cases of leprosy the bacilli are often found in the internal organs, but when the functions of the internal organs are severely affected it is generally due to amyloid or some other form of cell degeneration, the result of absorption of toxins from septic sores, and is not due, directly at least, to the presence of lepra bacilli in the affected organs. Exceptions to this are leprosy of the lungs and the testis, but the former is very rare and the latter, being painless, is seldom complained of and is certainly not likely to lead to a fatal result.

acute febrile and other toxic symptoms may occur while the number of bacilli is still comparatively small.

The apparent cause of this is that, as the bacilli multiply, they secrete a glutinous substance which fastens the newly-formed bacilli to the bacillary mass or to the cells lining the lymph spaces, and this substance, which envelops the bacilli, prevents the setting free of toxins. Under certain circumstances,

FIG. 1.

Photograph of a sweetmeat-seller who is able to carry on his business and enjoys fairly good health.

however, changes take place either locally or throughout the body which affect the bacilli and their glutinous matrix, toxins are set free, and febrile and other symptoms occur. Not only are toxins set free, but bacilli also are very often set free and carried to other parts of the body where, under favourable circumstances, they form new foci and lead to a further extension of the disease.

What the circumstances are which bring about the above-mentioned changes in the bacilli and their matrix I do not intend to discuss here, suffice it to say that the injection of certain drugs, the application of counter-irritation, and various febrile diseases are among the commonest causes.

The condition of leprous lesions may be conveniently divided into three phases according to their state at the time being, as judged by the appearance of the bacilli and their effects on the surrounding tissues. The first is the *quiescent* phase in which the bacilli multiply without giving out toxins. There is very little tissue reaction as shown by cell infiltration and fibrous tissue formation, and the bacilli are more or less uniform in shape, size, and staining. In the second or *reactionary* phase, toxins are set free and all the appearances of an inflammatory reaction are produced. There is an increase in the number of cells which infiltrate the lesions affected and dilatation of the capillaries and other local blood-vessels. Externally, the lesion is erythematous and raised bove the level of the surrounding normal skin. The acilli, instead of staining uniformly, stain only in parts, so that they have a dotted or granular appear ance; some of the bacilli stain uniformly faintly an others show spores or gonidia which, when stained fo half an hour in cold fuchsin and then decolorised fo two minutes in 10 per cent. nitric acid in absolut alcohol, take on a much darker stain than the ro part of the bacillus. These spores are more than twic the thickness of the rod and appear at the centr or end of the rod or else separately apart from th rod. There is good reason to believe that both th granular and the spore forms indicate that the bacil are either being destroyed or are at least in unfavou able conditions for growth and vegetation. Suc reactions may be local or general, some of the lesion or all of the lesions being affected. Part of a lesio or the whole of it may react and some of the bacil may be affected, others remaining as they were. I the third phase, which may be called the phase *resolution*, the swelling, erythema, and other signs the preceding inflammatory phase disappear. Ski lesions, which have reached this phase, will show th appearance of crushed tissue paper on the surface This is due to the thinning of the epithelium whic took place in the inflammatory phase as the result the pressure of the underlying corium, a wrinkle surface now showing as the inflammatory pressu has been removed. In this phase the cell infiltratio is replaced by fibrous tissue to a certain extent an the bacilli which have become granular during th inflammatory phase gradually disappear. The exten to which resolution takes place varies with the severit of the preceding reaction.

Leprous lesions are constantly passing throug these three phases, but, while the older lesions a reacting, the fresher lesions are spreading to th adjacent lymph spaces. This process may be see (Fig. 2) in radially-spreading, superficial lesions, an is very well shown in slightly pigmented skins whe we find an outer zone of depigmentation correspondin with the quiescent, non-inflammatory spread of th bacilli; inside this there is a raised, erythematou zone corresponding with the phase of reaction; whi in the centre erythema and swelling have bot disappeared, representing the phase of resolutio We may thus have the three phases coincidently i one lesion, or we may have the three phases succeedin one another, reaction having been suddenly set u in quiescent lesions due to some known or unknow cause and being followed by resolution.

In the reactionary phase not only is there settin free of toxins, but there is also setting free of bacil in the blood-stream. Many of these are carried a emboli to other parts of the skin and show thei presence by the formation of small inflammator nodules. In the third stage, or when in the first an second stages the general tissue resistance is sufficien these nodules quickly disappear, the bacillary embolu having been absorbed. When, however, either th general resistance or the acquired immunity are no sufficient to destroy the bacillary embolus it form the centre of a new focus from which the bacil spread once more through the lymph spaces.

Treatment.

In order to understand the lines along whic treatment may be successfully carried out, it i necessary to consider the significance of: (1) Th general body resistance; (2) immunity as indicate by the stage at which the patient has arrived; (3) th phases through which lesions pass to resolution.

It may be asked: "If leprosy is a self-healin disease like the acute, febrile diseases, what is th need of treatment?" The answer is that leprosy though not as a rule a fatal disease, is one of th most dreaded because of the deformity and disabl ment which it causes, and the object of treatment i to cut short its course in the first and second stage and, where it has already reached the third stage, t hasten the resolution of the lesions by causin moderate reactions.

A. In the first stage we have the disease in a limite form with few bacilli in the body, little or no acquire

immunity, and either diminished general resistance (temporary or permanent) or the presence of some other condition which is favourable to the increase of the disease. Attention in this stage must therefore be directed to: (1) The diagnosis and removal of whatever diseased condition, environment, or unsuitable diet is lowering the general tissue resistance or making the tissues a suitable medium for the growth of the lepra bacillus. (2) The induction of immunity by the injection of antigens. Defatted acid-fast bacilli may prove useful. (3) The destruction of lepra bacilli by the injection of preparations of fatty

FIG. 2.

Radially spreading leprous lesions of the back. Lepra bacilli could be found in the erythematous zone of some of these lesions. (From a coloured drawing.)

a = Large lesion caused by the coalition of smaller radially spreading lesions.
b = Depigmented outer spreading margin.
c = Erythematous inner spreading margin.

e = Normal skin.

acids. I have found the esters of the fatty acids of hydnocarpus and chaulmoogra oils specially useful for this purpose. Counter-irritation by infiltrating esters into the subcutaneous tissue under skin and nerve lesions or by the external application of such substances as trichloracetic acid (a 1 in 3 solution in distilled water painted on to lesions every six or ten days).

B. In the second stage the same remedies should be used, but with more care. The bacilli are plentiful and there is grave danger that, in the absence of acquired immunity, further dissemination of the disease may take place, as is frequently the case if violent reactions are allowed to occur. Even greater stress must be laid on the necessity of increasing the general resistance. Theoretically, antigens in the form of defatted acid-fast bacilli should be useful, but I have not yet had sufficient experience of their value to speak with confidence. Trichloracetic acid used as mentioned above is very valuable. The esters of the fatty acids are very useful, but they must be used with great care especially if the general health is not good.

C. In the third stage, where a fair degree of immunity has been acquired, all the above-mentioned forms of treatment should be pressed. Vaccines, however, are not of much use as compared with the other forms of treatment. Considerable reactions are generally followed by marked improvement and there is not the danger of an increase of the disease which there is in the second stage. Large injections of the esters of fatty acids may be given, and, when these do not have sufficient reaction-producing effect, the reaction level may be lowered by the oral administration of potassium iodide, beginning with a daily dose of half a grain and gradually working up the dose to the limit of the patient's tolerance. Many patients will react with small doses of the esters when under the influence of potassium iodide in whom large doses of the esters without iodide produced no reaction. This effect is dependent on the presence of large numbers of lepra bacilli in the body. Many leprous patients will complain of severe pains in the limbs and head after the administration of a quarter to one grain daily for a few days. It is then well to stop its administration for a few days and to renew it after the pains have subsided. In all the stages of leprosy regulation of diet, abundant exercise, and careful regulation of the bowels are absolutely essential if good results are to be obtained. I have dealt with the details of treatment elsewhere.[2] [4]

Prognosis.

The fact that leprosy is a self-healing disease is also of great importance in the prognosis. When a case has passed through the third stage there is but little chance of recurrence of the disease. In India many of the begging lepers who present their deformed limbs to passers-by in the hope of exciting pity are no longer suffering from the active disease. Careful post-mortem examination fails to find any lepra bacilli. In many of such cases perforating and other ulcers from which they suffer are trophic and are due either directly to defective nerve-supply following fibrosis of the peripheral nerves or to burns and cuts incurred through anæsthesia and insensibility to injuries. Such cases are almost entirely the result of neglect, but they cannot be said to be suffering from leprosy after lepra bacilli have been eliminated from the body. Many of them are cures of Nature, though the cure may be considered as worse than the disease, and they illustrate the fact that leprosy has a tendency to self-healing.

Under careful treatment, however, leprosy may heal with little or no deformity; and, when the patient has passed through the third stage, there is good reason to believe that there is sufficient immunity to ensure that there is only a remote chance, if any, of a return of active disease. When a patient, who has passed through the third stage, has, during a period of two years, given only negative results on repeated bacteriological examinations, and when there has been during that period no sign of fresh anæsthetic lesions and no increase in the size of any of the existing ones, I consider that he is cured. If, however, lesions have disappeared with or without treatment during the first or second stage, and two years with negative bacteriological examinations have passed; or, in nerve leprosy, if the anæsthetic lesions have to a great extent regained sensation and no new lesions have appeared during that period nor have any of the old lesions increased in size, the case should be considered one of *relative* cure, though the absence of immunity does not justify the prognosis of an *absolute* cure.

Cases such as have been referred to above, where the general resistance of the tissues has been lowered by some temporary cause, such as an acute fever, and the leprous signs, which have appeared during the period of lowered resistance, disappear again as the resistance returns—such cases must be distinguished from those in which the disappearance of leprous lesions is due to acquired special immunity. Recurrence is not uncommon in the former if at any future date the general resistance is again lowered; recurrence in the latter seldom or never occurs.

Obviously, one of the chief difficulties which will arise in the mind of the reader is how to tell with certainty which particular stage the patient has reached. I have dealt with this in more detail elsewhere.[3] To anyone who is familiar with the appearance of resolved and resolving leprous lesions the difficulty is not so great as would at first appear. There is, of course, no clear-cut line between the different stages, but in a case which has advanced as far as the doubtful border-line between the second and third stages, no harm will be done by treating the case as one in the third stage. Unfortunately, no complement-fixation or other serum reaction has been discovered which is of any value in testing the specific immunity in leprosy and we must rely for our evidence upon clinical signs.

Summary.

1. Leprosy is a self-healing disease, in typical cases of which immunity is gradually produced.

2. Delay in immunity production is due to the nature of lepra bacilli which are able to multiply with few or no signs of local or general toxæmia.

3. During the first two stages of leprosy it is most important to restore the lowered tissue resistance, otherwise the disease may pass on into the third stage.

4. In the third stage, where immunity has been produced, it is important to bring about moderate reactions so as to hasten the resolution of the lesions before deformity and disablement can take place.

5. In cases which have passed through the third stage an absolute cure may be hoped for as far, in many cases, as the active disease is concerned; while in cases which have recovered without passing through the third stage the cure can only be considered a relative one, recurrence being possible should the tissue resistance be seriously lowered at any future time.

THE EFFECT OF ALTERATION OF TEMPERATURE UPON THE RATE OF THE ISOLATED HEART.

BY W. M. FELDMAN, M.D. LOND., F.R.S. EDIN.,
PHYSICIAN, ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, PLAISTOW;

AND

A. J. CLARK, M.D., F.R.C.P. LOND.,
PROFESSOR OF PHARMACOLOGY, UNIVERSITY COLLEGE, LONDON.

ON theoretical grounds it can be shown[1] that the effect of heat upon the velocity of a chemical reaction should obey a certain law which can be expressed symbolically as follows:—

$$\log \frac{K_2}{K_1} = \frac{Q}{2} \frac{(T_2 - T_1)}{T_1 T_2}$$

where K_1 and K_2 are the reaction velocities at the absolute temperatures T_1 and T_2 respectively, and Q is a constant.

This is known as the Van't Hoff-Arrhenius law, and has been found in practice to hold good for all chemical reactions.

There are many vital processes which have been shown by various observers to be affected by temperature in accordance with the same law. Barcroft, for instance, found that the dissociation of oxyhæmoglobin, at various temperatures, takes place in agreement with this law, a point of some considerable importance to the animal body, since the increased dissociation of oxyhæmoglobin resulting from the rise of temperature produced by ordinary muscular work provides more free oxygen for the increased needs of the active tissues. The development of the tadpole has been shown by O. Hertwig to follow the same law[2]; phagocytosis is another interesting example, according to Madsen,[3] of the same thing, whilst the law of increased conductivity of a nerve under rise of temperature is well known to everybody.

In a paper by one of us (A. J. C.) upon the effect of temperature on the frequency of the heart,[4] the statement was made: "In both the frog and the rabbit the frequency of the heart is not a linear function of the temperature, nor is it a simple logarithmic function." This statement requires modification, for we find that when numerical results upon which that statement was based are subjected to exact mathematical analysis they are found to obey the Van't Hoff-Arrhenius law in a very satisfactory manner. Thus, in the case of the isolated auricle of the rabbit's heart the figures shown in Table I. were obtained:—

TABLE I.

Temperature (Centigrade)	15	25	30	34	38
Rate (per minute)	25	64	82	120	170

Using the Van't Hoff-Arrhenius formula we get values of Q which range between 13,730 and 16,130, with a mean value of Q = 14,835. The maximum deviation from the mean—i.e., 1295 (viz., 16,130 − 14,835) can be shown by statistical methods[5] to be within the limits of experimental error.

If now we use this value of Q to calculate the theoretical rate of the auricle at the given temperatures, we obtain the figures given in Table II.:—

TABLE II.

Temperature		15	25	30	34	38
Rate	Observed	25	64	82	120	170
	Calculated	(25)	59·5	89·6	123·4	174·3

It will be seen that the agreement between the calculated and observed results is a very satisfactory one. When the original figures are plotted, the resulting graph is neither a straight line nor a simple logarithmic function, but if we plot the logarithms of the corrected (calculated) figures against temperature the graph is a straight line, as we should expect.

In another set of experiments with the frog's heart (perfused with alkaline Ringer of pH = 9), given in the paper referred to, we find the observed and calculated results at various temperatures to be as shown in Table III.:—

TABLE III.

Temperature	0·4	5·6	6·4	12·8	13·6	14	16	21	29·5
Rate—									
Observed	5·9	11·7	13·25	25·25	26	30	36	52·5	84–92
Calculated	(5·9)	10	12·28	25·89	28·41	29·7	37·9	64·3	156

So that up to a temperature of 20° the agreement is excellent. It is possible that at a higher temperature there is a coagulation or other chemical change of the protoplasm of the frog's heart which accounts for the divergences between the expected and observed results at 21°, and especially at 29·5°. Similarly, it would appear that normal Ringer, with weak buffer ($NaHCO_3 = 0{\cdot}015\%$; pH = 8) has some chemical influence upon the heart muscle, since experiments carried out with isolated frog's heart perfused with that solution give results which are not in agreement with the Van't Hoff-Arrhenius law.

It would be interesting to have exact observations of the normal pulse-rate in man under the normal cyclical daily variations in temperature. Such observations would be of value from the point of view of variations of pulse-rate under various pyrexial conditions, inasmuch as they would enable one to ascertain whether any particular pyrexial condition

has or has not a chemical action upon the protoplasm of the cardiac musculature. This is a point which we hope to investigate in the near future.

Conclusions.

1. The rates of the isolated heart of the frog and rabbit under different temperatures are such as would be expected from the Van't Hoff-Arrhenius law.

2. Within certain ranges of temperature it is possible to foretell by means of that formula what the rate of the heart should be under any particular temperature.

3. Marked divergences between the observed and calculated results—when gross errors of observation can be eliminated—point to some chemical changes in the heart muscle, due either to the high temperature or to nutritive fluid supplying the heart.

ACIDOSIS IN RELATION TO ACUTE RICKETS.

BY NORMAN BURGESS, B.A. CAMB.,
AND
A. A. OSMAN, M.R.C.S., L.R.C.P.,
CHIEF CLINICAL ASSISTANT, CHILDREN'S DEPARTMENT, GUY'S HOSPITAL.

(*From the Department for Diseases of Children, Guy's Hospital.*)

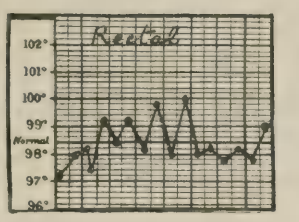
IN view of recent discussion of the nomenclature of this subject it should be stated at the outset that the term acidosis, as used in this preliminary communication, refers to a variation in the acid-base equilibrium in the blood, with a lowered plasma bicarbonate, and not to any particular form of acid intoxication. Evidence has been accumulating, from many sources, that acute rickets is frequently associated with a condition of acidosis, since this was first described by Hertzmann in 1873.[1] The subject has recently been revived by Pritchard[2] and others, who regard acidosis, however produced, as the *essential* factor in the ætiology of this disease. Such a theory appears to be based largely upon determinations of the calcium and phosphorus content of the blood and excreta, together with estimations of the ammonia-nitrogen and the detection of acetone bodies in the urine. So far as we have been able to ascertain, no direct measurements of the alkaline reserve of the blood in acute rickets have yet been published; we have recently had the opportunity of making such investigations, together with observations on the urine and fæces in three cases of acute rickets, and believe, therefore, that the publication of a preliminary communication embodying our results, few as they are, may be of value to other workers in this field.

Notes of Cases.

On account of the difficulty of obtaining a precise definition of a condition so protean in its manifestations as acute rickets, and realising that the title is ambiguous, it has been deemed advisable to give a somewhat detailed clinical description of the cases studied.

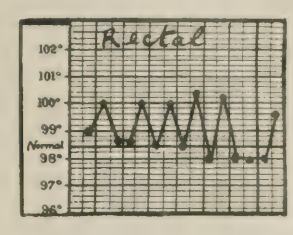
CASE 1.—Female, aged 3, a full-time child weighing 6½ lb. at birth. Entirely breast-fed and weaned at 13 months. Had measles at 2 years, after which she walked badly and "fell about." Home situated in a very poor neighbourhood, the total family income (parents and two children) being 22s. per week. For the past 18 months the average diet consisted of:—Breakfast: bread, margarine, tea, and occasionally an egg; dinner: always some kind of meat, potatoes, and greens, and sometimes a rice pudding; tea: bread and margarine. In June, 1923, she was noticed to be very fretful and listless and began to sweat more than usual. She was admitted to hospital on July 9th, 1923, under Dr. H. C. Cameron, as a case of acute rickets. The most striking clinical feature was the extreme hypotonia of the limbs and musculature generally. There was slight pyrexia (Chart 1) but no obvious anæmia. The spleen was not palpable. Beading of the ribs was marked, and there was considerable enlargement of the wrists and ankles; bowing of the tibiæ was also present. X ray examination of the epiphyses showed cupping, and the typical appearance of acute or florid rickets. The child was placed in a cot so situated that she was not in direct sunlight, and was put on light full diet, comprising bread, butter, milk, potatoes, green vegetables, cooked meat, rice pudding made with milk, and water as required. No cod-liver oil or other medicine was given.

FIG. 1.



Case 1.—Temperature chart, July 9th–16th.

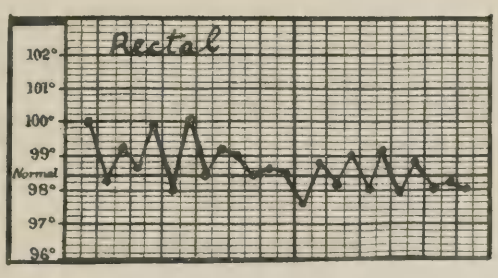
FIG. 2.



Case 2.—Temperature chart, July 9th–16th.

CASE 2.—Female, aged 18 months, sister of Case 1, living under the same home conditions, and on practically the same diet. No history of any previous illnesses. Symptoms the same as in Case 1, and began about the same time. On admission on July 9th, 1923, the chief feature was the extreme hypotonia. There was slight pyrexia (Chart 2). Clinically, there was no difference between the two cases as regards the severity of the process, but X ray examination showed slightly less bony change in Case 2. She was placed in an adjacent cot, and on the same diet as her sister, and was not given cod-liver oil or other medicine.

FIG. 3.



Case 3.—Temperature chart, August 29th–Sept. 10th.

CASE 3.—Male, aged 1 year and 8 months, the youngest of three children. A full-time child, breast-fed for three months, then given cows' milk and barley-water. For the last seven months he had been having a diet as follows:—Breakfast: bread, margarine, sugar, and jam; cows' milk 1 pint per diem; dinner: mashed potatoes, gravy, rice; tea: milk, bread, and margarine. Had been crawling about for some time, but does not stand or talk. It was not possible to determine the date of onset of the symptoms. Anterior fontanelle still patent; marked beading of ribs, and enlargement of wrists and ankles. As in Cases 1 and 2, the most striking feature was the extreme hypotonia. Slight pyrexia (see Chart 3). X ray examination showed advanced rickety changes and cupping of about the same degree as Case 1. This case was in hospital on the same diet as the two previous cases, and was not given cod-liver oil or other medicine. The investigations were carried out 24 hours after admission.

The cases were confined to bed throughout the period under review.

We wish to emphasise the "acuteness" of the process in the above cases, and as this stage probably

only lasts for a comparatively short period, a few weeks at the most, it is important that observations such as are recorded here should be undertaken quite early in the disease.

*Investigations and Methods.**

The investigations carried out comprised determinations of the bicarbonate content of the plasma from venous blood, and in Case 3 the acetone bodies in the blood. Quantitative estimations were made of the total acetone bodies and the ammonia-nitrogen ratio in the urine. Special precautions were taken in collecting the specimens to ensure that no ammonia should be introduced from without. The specimens were collected into sterile and specially cleaned bottles. Bacteriological examination of the specimens remained sterile up to 72 hours. In Case 3 the percentage of fat in the fæces was determined. The plasma bicarbonate values were obtained by the titration method of Van Slyke, Stillman, and Cullen[3] the full precautions indicated in their paper being carried out. Instead, however, of determining the reaction of each sample of blood taken, the titration was made to a constant end-point pH 7·4. The results are expressed as molar concentration of bicarbonate, each figure being the average of at least two readings. The total acetone bodies in the blood were estimated by the method of Van Slyke and Fitz.[4]

The total acetone bodies in the urine were determined by the method of Van Slyke,[5] the mercuric precipitate being dissolved in dilute hydrochloric acid and titrated with potassium iodide as described in his paper. The results are expressed as molecular concentration of acetone. The ammonia-nitrogen was determined by formol titration: the fat content of the fæces by the Schmidt-Werner method (as used by Cammidge).

Control observations were carried out both on blood and urine of other children in the ward convalescent from various disorders other than rickets. Unfortunately, the control figures for blood and urine were not obtained from the same cases. Both Cases 1 and 2 were in hospital for three days before observations were commenced.

Results.

Blood.—The values obtained for the plasma bicarbonate were: Case 1, 0·0174; Case 2, 0·0190; Case 3, 0·0183. The average value in the controls was 0·0313, which approximates very closely to the figure obtained with this method in a larger series of normal adults—viz., 0·0345 (males) and 0·0319 (females). A further determination on Case 1 after a period of 11 days, during which time the acetone bodies had disappeared from the urine, gave a value $NaHCO_3 = 0·0166$.

It is unfortunate that the figures obtained are so few, but it is scarcely possible to obtain repeated samples of blood from young children whilst observing all the precautions necessary for accurate work with this method. In Case 3 the blood withdrawn at the same time as the sample on which the plasma bicarbonate determination was carried out was examined for acetone bodies. They were found to be entirely absent from the blood.

Urine.—In Case 1, on the first two days of investigation, the urine gave a strong Legal reaction for acetone bodies, but the ferric chloride reaction was negative. A quantitative estimation of the acetone bodies was only carried out on the first day, as it was impossible to obtain a sufficiently large specimen on the second day. The value on the first day was 0·0096. No acetone bodies were present in the urine of Case 1 after the second day. In Case 2 the difficulty of obtaining specimens was much greater. Only on two occasions could a sufficient quantity be obtained. These contained no acetone bodies. No acetone bodies were present in the urine of the control cases. In the cases under consideration the average NH_3/N_2 ratio was 14·3 per cent. In a series of controls the average value was 7·04 per cent. These figures for the NH_3/N_2 ratio correspond approximately with those obtained by Dr. Amy Hodgson,[7] who obtained an average NH_3/N_2 ratio of 14·3 per cent. in 13 cases of rickets, as compared with 6·2 per cent. in a series of normal children. The results are expressed below in tabular form so that the dates on which determinations were made can be clearly seen and compared.

Case.	Date in 1923	$NaHCO_3$.	NH_3/N_2 per cent.	Acetone in urine.	FeCl.	Legal.	Roths.
1.	12/7	0·0174	14·1	0·0096	−ve	++ve	++ve
	13/7		13·8		−ve	++ve	++ve
	16/7		11·9	Nil.	−ve	−ve	−ve
	23/7	0·0166		,,	−ve	−ve	−ve
2.	12/7	0·0190		,,	−ve	−ve	−ve
	14/7		14·1	,,	−ve	−ve	−ve
3.	30/8	0·0183	17·6	,,	−ve	−ve	−ve

Fæces.—The fæces of Case 3 contained 17·5 per cent. of fat. The following report on the fæces of Case 1 was made by Dr. J. H. Ryffel: "Fæces are loose. Acid to litmus, not to Congo-red. No appreciable excess of fat. Stain blue with iodine, staining being due to granules which look more like yeasts than starch grains."

Discussion of Results.

The results recorded above, although few in number, by their variety and in comparison with the results of other workers, indicate a line of research which we shall hope to pursue when further material becomes available. The results of determinations of the plasma bicarbonate and acetone bodies in the blood and urine form an interesting comparison with figures recently obtained in a series of cases of diabetes mellitus.[8] In the latter cases it was found that the diminution of the plasma bicarbonate corresponded fairly closely with the total acetone bodies present in the blood; this, as we have shown, is far from being the case in acute rickets, although in each case there was marked diminution in the alkali reserve. In two out of the three cases no acetone bodies were present while in the other case, although the plasma bicarbonate was still lower 11 days after the first observations were made, the ketosis disappeared after four days and did not reappear. So far our results would tend to show that there is a severe acidosis in acute rickets in which the acetone bodies play no part. This would lead to the conclusion that the acidosis is due to one or both of the following factors: (1) Loss of bases by some other channel—e.g., fæces or urine; (2) some other acid bodies present in the blood. With regard to the former, Dodds[9] records a high fat content in the fæces of children suffering from acute rickets, and concludes that there is evidence of pancreatic disorder in acute rickets. Braithwaite[10] however, was unable to confirm this result, and points out that Dodds neither defined the term acute rickets nor stated in his article whether the cases were having cod-liver oil and malt as part of their treatment. In Case 3, in which we determined the percentage of fat in the fæces, our results were in agreement with those of Braithwaite, since we obtained a normal figure. Dr. Ryffel's report on the fæces in Case 1 seems to point in the same direction. The second point—viz., whether there are other acid bodies circulating in the blood, thus causing a depletion of the alkaline reserve, is at present a matter of pure conjecture.

In conclusion, we wish to express our thanks to Dr. H. C. Cameron for permitting us to investigate his cases, to Dr. W. W. Payne and Dr. E. P. Poulton for kindly help and criticism, and to Dr. J. H. Ryffel for placing the resources of his laboratory at our disposal. One of us (N. B.) wishes to acknowledge with thanks a grant from the Parsons Research Fund.

(*Continued at foot of next page.*)

* It may be of interest to note that the weather during the course of the investigations of Cases 1 and 2 was extremely hot, the shade temperature (ward) at the time the first two blood samples were taken being 82° F.

BACKACHE.*

BY R. H. PARAMORE, M.D. LOND., F.R.C.S. ENG.,
GYNÆCOLOGIST, HOSPITAL ST. CROSS, RUGBY.

BACKACHE is such a common complaint, is associated with so many different conditions, receives as a rule such scant consideration, that no apology is needed for bringing it forward for discussion. Straub [1] states that it is not only one of the commonest complaints, but that, "ætiologically considered, it is one of the most difficult to deal with," and that "in no field of medicine is there greater ignorance as to . . . . cause and conditions."

I turn to Lovett's [2] paper of 1914, a paper full of interest, for the introduction to my argument. Lovett dealt with chronic backache; the following is a slightly modified form of his classification:—

Backache: Lovett's Classification (1914), Modified.

1. *Gynæcological: Disease or Displacement.*
   (*a*) Direct reflex influence.
   (*b*) Flexed position of body = Fatigue or strain of erector muscles.
2. *Traumatic.*
   (*a*) Arthritis of spine.
   (*b*) Defective balance = Fatigue or strain of erector muscles.
3. *Arthritis of Spine.*
   (*a*) Stimulation of pain fibres.
   (*b*) ? Lowered resistance of body = Fatigue or strain of erector muscles.
4. *Other Local Origin.*
   (A) Static in origin.
   (*a*) Skeletal peculiarities: shortness of one leg, body inclined sideways.†
   (*b*) Lack of proper muscular control—
   "Slumped attitude" } Body inclined forwards.†
   ? Flat-foot }
   (*c*) Abnormal conditions of abdomen—
   Corpulence } Body inclined backwards.†
   (Advanced pregnancy) }
   (B) Sacro-iliac joint—
   (*a*) Strain of—Attitudinal.†
   (*b*) Relaxation of—Non-proven.‡

† Fatigue of erector spinæ muscles.
‡ It must be left to orthopædists to decide whether this opinion stands to-day.

Lovett left out many conditions in which backache may be complained of—caries, cancer, hydatid of the spine, aneurysm, pneumonia, pleurisy, renal calculus, nephromata, gall-stones, appendicitis, ovarian tumours, fibroids, cancer of the womb, nephroptosis, organic nervous disease, small-pox, and influenza. But by excluding all these he emphasises the great rôle played by fatigue of the back muscles in the causation of backache in the types he considers. It therefore seemed advisable to get at the cause of this fatigue of the erectors, and, as a corset was nearly always found to benefit the patient greatly, to ascertain the way in which the corset acts. Flat-foot and similar conditions, according to Lovett, occasion backache by inducing disturbance in antero-posterior balance.

Backache and the Erector Spinæ Muscles.

Two questions then arise: First, how can flat-foot per se cause backache? Does it occasion strain of the erector muscles; and, if so, how? Secondly, is backache, in the types of case mentioned, due to strain or fatigue of the erector muscles; and, if so, how is it that the therapeutic corset relieves? If backache of these types is not due to strain of the erector spinæ muscles, to what is it due? I address myself to the second of these questions, leaving the first to the orthopædist and to the general practitioner. It seems to me, however, that the flat-foot and backache, which apparently appear so often in conjunction, are due to a common cause—a general bodily weakness or depression of the vital forces. Flat-foot must be attributed to a general depression; or, if purely local, it must have some special cause. It is a result of too much strain on the tibialis posticus and allied muscles; but why should these become incapable of performing their function efficiently, if the general resistance of the individual is not depreciated and the bodily vigour remains good? I consider it significant that in a patient with flat-feet mentioned by Lovett, complete freedom from backache did not occur until a corset was applied. The fact that omission to wear the foot-plates was marked by a return of the backache which disappeared with their renewal is interesting, and essentially an orthopædic question. The effect of the corset, applied especially to the lower abdomen, is what interests me; my argument is that it favourably affects general metabolism and thus not only relieves strain of the erector muscles but assists in the performance of function by all body parts, and thus materially participates in the recuperation of such a condition as flat-foot.

Leaving aside for a moment Lovett's defect in lateral balance, it is rather interesting to observe that he depicts two different types of defect in antero-posterior balance. On the one hand, he attributes the backache of gynæcological disease and of "slumped attitude" to the patient inclining the body forwards; and on the other, the backache of corpulent people to the enlargement of the abdomen, in which case the body is inclined backwards. These two attitudes are essentially different in one particular: in the former, owing to the flexion of the spine, the erector muscles are extended—lengthened—stretched; in the latter, owing to the extension of the spine, the erector muscles are almost as short as they can be. In the former case, in spite of their extended state, they have to contract more strongly than if the individual were erect—and it is not surprising that under such conditions they should become easily fatigued. Backache is perhaps most readily induced in normal healthy man by his working in an unaccustomed stooping position; how often does one hear of patients being afflicted with lumbago after digging in the garden! You will see at once that the erector muscles are maintained unduly stretched by the attitude, but that at the same time they must work harder, contract more strongly, than during such an exercise as walking. In the other type of case—that of a corpulent man or that of a woman in advanced pregnancy—though the protrusion of the abdomen carries the centre of gravity forwards, the shoulders are thrust back, so that an equipoise is obtained. To maintain the shoulders back, to carry the trunk and head erect, the erector muscles must surely do more work than in a healthy non-corpulent or non-pregnant individual.

Is this, then, the cause of the backache in these cases? That it is so seems indicated by a case of defect in lateral balance, cited by Lovett; with an inch shortening of one leg, the patient complained of backache and was cured by a high sole on the boot of the shorter leg. In this case the backache can only have been due to the extra work thrown on the erector spinæ, which had to do its work in a stretched

* Read at a meeting of the Rugby and District Medical Society, Dec. 1st, 1923.

state because of the lateral deviation of the spine which the condition determined. But if we accept this as a cause of the backache in this case, and attribute the backache in corpulent people to the increased strain on the erector muscles, we are immediately met with a difficulty. If the erector muscles, because of the attitude, have to work harder—if the backache in these cases is due to the extra strain thrown on these muscles—why do they not hypertrophy, and by increasing in mass, become able to deal with the situation?

The Basis of Muscle Hypertrophy.

Nothing in medicine is more fascinating than the study of the reactions of muscle. Life is simply a series of postures and movements; to understand these is to understand all. A consideration of the mechanism of muscle hypertrophy—of the determining and opposing factors—throws much light on many vital processes. One of the important features to remember is that an increase in work is not the only factor brought into play; besides the demand for an increase in contractions—tonic and other—an increased blood supply is necessary. This is required not only to ensure an adequate oxygen and foodstuff supply, but especially for the removal of the katabolic products, now increased. Similarly, the blood must be of a certain quality—it must not already be laden with too great a percentage of waste products, nor must it be deficient in those bodies on which anabolism depends. In short, the visceral machinery must be in such a state that it can not only furnish an adequate amount of blood per unit of time to the tissue in question, but of blood of adequate quality. To effect this it must be working at less than top speed—that is to say, it must be in such a state that it can respond to the needs of the moment, to the increasing demands now made on it; and, if these persist, can itself hypertrophy. In people with lax abdominal walls—whether corpulent or not—and in certain cases of pregnancy this machinery is not at its best: the conditions for hypertrophy do not sufficiently obtain, organs have to do more work than they can, strains thus accrue when they should not, and fatigue is experienced sooner than it ought.

The Working of Intra-Abdominal Pressure.

A word as to how this intra-abdominal pressure works—the pressure due to the contractile activities of the abdominal muscles, especially of the flank muscles, acting as they do in concert with the thoracic diaphragm and pelvic floor. This pressure works in two ways. How it affects the visceral capillary circulation, the flow of blood per unit of time through the stomach and intestines, the pancreas and spleen, the liver and kidneys: how it tends to flatten the visceral capillaries and conversely occasions reflexly a corresponding dilatation of the supplying visceral arterioles (other forces remaining the same) are questions with which space will not permit me to deal. I wish, on this occasion, to emphasise the other more obvious effect of the intra-abdominal pressure, its effect on the heart—that is, on the output from the left ventricle—and its effect, consequently, on the aortic blood pressure. The intra-abdominal pressure has this effect by controlling or influencing the supply of blood to the heart (right auricle). If the supply of blood to the heart is poor, the output must correspond, so must the aortic pressure. There are only three regions—omitting the skin and subcutaneous tissues—from which blood is returned to the heart (right auricle): these are the skull, the limbs, and the abdomen. Owing to the nature of the skull, blood cannot accumulate within this part. The limb muscles, too, are invested with inextensible aponeurotic membranes, so that blood cannot accumulate to any extent in the limbs. But in the abdomen it is different; there great variations in volume and capacity are constantly occurring, and with lax abdominal walls, blood can readily accumulate. By applying an efficient corset or belt the pressure within is raised, the blood can less readily accumulate, more per unit of time is pressed into the thorax and right auricle, reaches the left ventricle, and is thrust into the aorta. The aortic blood pressure thus rises, more blood per unit of time thus traverses the brain, the limb muscles and back muscles, the viscera of the abdomen. The whole individual becomes improved; muscles or glands or other parts, which before could not hypertrophy in spite of increasing demands made upon them, find themselves now able to deal with the situation in hand. The tonic contraction of muscle is greater, the cerebral response is enhanced, gland activity is increased—the neurasthenic gets well. It is not surprising that, if backache in the cases mentioned is due to fatigue spasm or strain of the erector muscles, such a measure should relieve the condition. The success of the treatment is an indication of the soundness of the explanation, and if it is applied in practice most gratifying results will be obtained.

Surgical Treatment of Backache.

So much for the academic consideration of backache. I have already taken up so much of your time that I do not intend to discuss at length the cases of backache which have come under my care, but before I close I should like to say something about the surgical treatment of backache. By this I do not allude to those measures orthopædists may practise, such as stretching the gastrocnemii, and such like; nor am I thinking of those operations by which the backache incident to inflammatory or other disease of the pelvic viscera is cured or relieved, or of the effect of nephropexy in this respect; I am thinking of specific conditions of the abdominal wall and of the pelvic floor, in virtue of which "static backache" arises, and of procedures by which the functions of these important musculatures can to a very large extent and in some cases completely be restored to normal.

It is clear, if the abdominal wall be lax, that a corset or belt, however well it fit, can only be effective in raising the intra-abdominal pressure if the pressure-resisting mechanism occluding the pelvic outlet be efficient. In patients suffering from so-called relaxed vaginal outlet, a condition in which the pelvic floor musculature is not efficient and does not act as the sphincter it should, the application of a corset or belt will only tend to make worse the backache and bearing-down pains, of which the patient complains or exaggerate the visceral extrusion which may already exist. To cure the patient, the pelvic floor itself must first be restored and the genital extrusion prevented. But lesions of the abdominal wall and pelvic floor, the common results of pregnancy and parturition respectively, are not always coexistent. Even in multiparous woman, with a markedly lax abdominal wall, one may yet find the pelvic floor in good condition and the vaginal orifice tightly screwed up. In such a case, attention to the abdominal wall alone is needed. On the other hand, it is frequent to find with a lax abdomen a lax or inefficient pelvic floor.

In practice I divide these patients into two classes according to their age, according as to whether or not they have passed the climacteric. After the climacteric, when the uterus is of no further service, and if malignancy can be confidently excluded, the interposition operation is best. The cervix is amputated, and the body of the uterus brought down and fixed beneath the bladder, between it and the anterior vaginal wall. In this position it acts as a natural pessary and cures effectually the cystocele so common in these cases and the incontinence of urine from which so many of the patients suffer. In younger women the ideal is to restore the displaced levator muscle to its proper position. During birth the muscle border is always more or less torn from its bony origin in front, and during the lying-in it takes up a more lateral anterior attachment, becoming more oblique. This change in position, which can readily be demonstrated clinically, results in a permanent widening of the pelvic floor aperture, and in marked cases is commonly associated with incapacitating bearing-down pains and

backache and the imminence of prolapse. The operation I have been practising, and from which I have been obtaining some good results, consists in exposing the muscle, severing it from its present more or less lateral attachment, and uniting it by sutures to the pubic arch near the middle line. By this means—if the new attachment persists—the pelvic floor aperture is much narrowed and the muscle becomes again efficient as a sphincter to the pelvis. In cases in which this has been done, and in which the abdominal wall is lax, a belt can now be worn with much advantage.

Inefficiency of the Abdominal Wall.

In other cases one finds the abdominal wall hopelessly inefficient. Examples of two types of case have come before me. In one, the linea alba is greatly stretched and remains so or gradually gets worse; in the other, the conspicuous feature is not a persistent separation of the recti, but marked laxness of the flank muscles outside. Examination of the abdominal wall in strained conditions brings out these features. By getting the patient when lying supine to raise the head and shoulders, the separation of the recti, if present, becomes clearly evident; whilst if a weakness of the flank muscles is the feature of the case, one can see these bulge at times extraordinarily. In such cases, the application of a corset or belt cannot hope to restore the function—if a belt be used the redundant abdominal wall rolls over it in an annoying fashion—but much benefit may accrue from surgical measures. I cite you two examples:—

A corpulent woman of 45, the mother of ten children, the last 5 years of age, consulted me complaining of backache. There was considerable separation of the recti, three or four inches at the level of the navel: the pelvic floor aperture was not much enlarged, but a small rectocele was present. On April 30th, 1923, I exposed the stretched aponeurosis between the recti in the whole of its extent, and pleated it longitudinally, so that at the end of the operation the separation was gone. A small colpo-perineorrhaphy was done at the same time. On Oct. 23rd the patient reported: she said she was "ever so well," she had had no further backache or bearing-down pains. The incision in the abdominal wall was then 13 in. long, and the girth of the abdomen 46½ in.

The other case is that of a woman who has suffered much at my hands:—

The patient is 57 years of age. Four years ago I removed the uterus for bleeding due to fibroids. In spite of wearing an abdominal belt from her convalescence, in about six months' time she complained of bad pain in her back and right thigh. Examination revealed considerable prolapse of the right kidney, which was stitched up in October, 1920. She got on fairly well until the spring of 1922, when backache was again a cause of complaint. I thought the pelvic floor was slackening and advised a pessary and a larger pad to the Curtis support. This relieved for a while, but at the end of that year the patient complained of a "dreadful pain" in the back "and through to the front." She stated she was always in pain, "could not sleep or lie still in bed," and "could not sit for many minutes in one position."

The abdominal wall was exceedingly lax, especially laterally; and on the left side in the region of the anterior superior spine of the ilium a hernia seemed present. Examination revealed the pelvic floor aperture in a fairly good condition: the pessary apparently had done some good. At my wits' end to know what to do for this patient, who was constantly coming to see me, I determined to advise doing a modified Lotheissen's operation on both sides—that is to say, bringing down the lower edge of the transversalis and internal oblique and stitching them to the ascending ramus of the pubes. This was done on both sides on Feb. 19th, 1923, a hernial protrusion being found on the left side as previously indicated. Unhappily, on coming out of the anæsthetic, the patient was found to be suffering from hemiplegia—evidently due to a cerebral thrombosis. She gradually recovered from this, and quite early in her convalescence stated that her backache had gone. Writing nine weeks after operation, she said: "I have not had any pain either in my back or at my front and I begin to feel much better than I have done for several years."

This would have been a good case had the patient remained well. Unfortunately, she has had two further attacks of thrombosis, or of what seemed to be thrombosis, from the last of which she is only now recovering. The first of these kept her in bed less than ten days; and now she wants to get up before a week is out. But she persists in stating her backache is gone, though pain in the right thigh continues.

Believing, as I firmly do, in the benefits which by surgery we can confer on humanity, and especially in those mechanical measures by which backache can be successfully dealt with, the question at times arises when plastic procedures have been done and the patient gets well and the old pain goes, whether the wish had not something to do with the thought—whether ceremonials are not after all of value. In many cases there is no doubt; the change in structure effected, demonstrable to one's senses, explains the altered outlook of the patient. It is true that the abdominal wall in this patient of mine had become greatly improved; in spite of that, and if she previously had backache (as I believe), I can only describe its relief by surgery as magical.

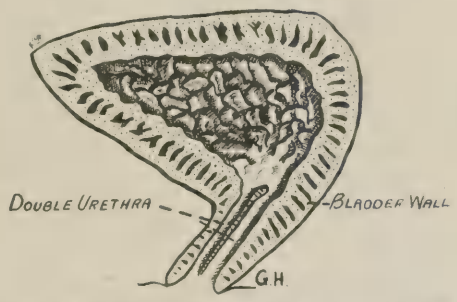
ANATOMICAL ABNORMALITIES.

BY GORDON HARROWER, M.B., CH.B. GLASG.,
PROFESSOR OF ANATOMY, KING EDWARD VII. MEDICAL COLLEGE, SINGAPORE.

DURING the spring term of 1923 a remarkable series of abnormalities came under my observation at the anatomy department of the King Edward VII. Medical College, Singapore. The subjects for dissection are drawn from the coolie class of Chinese, with occasionally a Tamil coolie. Female subjects are very difficult to obtain, as there is a minority of women of all nationalities in Singapore.

CASE 1.—The most noteworthy abnormality, one which I have not seen previously reported, occurred in a female Tamil subject. On making the usual median incision through the pelvic viscera the knife divided the urethra in its entire length, displaying a double channel with double opening into the bladder, and a single external urethral orifice. The urethra was divided by a very thin septum (Fig. 1), having a uniform thickness of 1 mm. in its entire

FIG. 1.



Case 1.—Double urethra, divided by a thin septum (width 1 mm.) along almost its entire length.

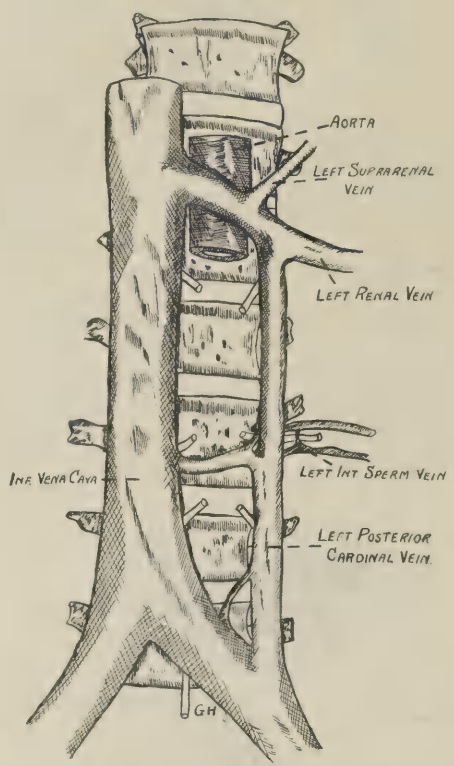
length except near the internal urethral orifice, where it was slightly enlarged and measured 3 mm. The condition at first sight appeared artificially produced, but scrapings were taken from each canal and examined under the microscope. Both canals were found to be lined by squamous epithelium. The internal urethral orifice of each canal was depressed, and the mucous membrane formed a ridge round each opening.

CASE 2.—In an adult male Chinese a persistent left posterior cardinal vein was found (Fig. 2). The vein extended between the left common iliac vein and the left renal vein, and measured 8 mm. in diameter. The vessel lay along the left antero-lateral border of the vertebral column, and received the lower three lumbar and internal spermatic veins of the left side. The corresponding lumbar arteries passed posterior to the cardinal vein. The upper extremity of the vessel opened into the left renal, 3½ cm. from the medial border of the left kidney. At the lower end a small communicating vessel passed between the posterior cardinal and the left common iliac. The left internal spermatic opened into the left border of the left posterior cardinal near its middle, and at the same level a small communicating vessel passed to the inferior vena cava.

From its position, relations, and tributaries the vessel is obviously a persistence of the lower part of the posterior cardinal of the embryo.

CASE 3.—In this subject my attention was drawn to the remarkably small calibre of the ascending colon and the absence of cæcum and appendix. On examination, however, I found that the cæcum occupied the position of the normal hepatic flexure. The cæcum lay in a horizontal position with its apex directed to the right. The appendix was turned upwards and to the left behind the cæcum. The position of the ascending colon was occupied by the terminal portion of the ileum, which had no mesentery, but had the same peritoneal relations as the normal ascending colon. There was a large retrocæcal pouch. This condition represents a failure in descent of the cæcum to the right iliac fossa after the rotation of the gut from the left iliac fossa to the right hypochondrium. In a similar case which came under my notice some years ago an inflammatory condition in the right hypochondrium, diagnosed as hepatic abscess, proved to be appendicitis.

FIG. 2.

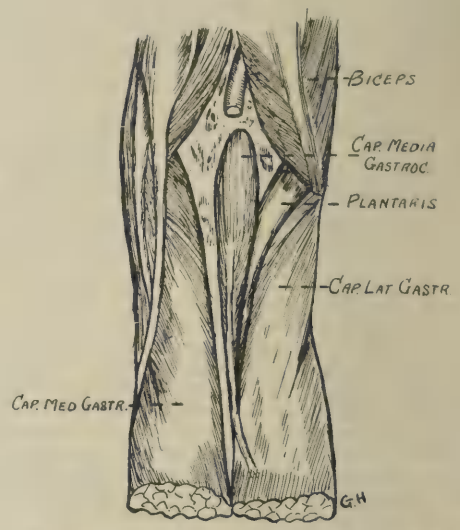


Case 2.—Persistent left posterior cardinal vein (diameter 8 mm.) extending between left common iliac and left renal veins.

CASE 4.—Another subject, also Chinese, provided an abnormality in the musculature of the popliteal region. This took the form of a small muscular belly which might be called the middle head of the gastrocnemius. It took origin from the middle of the planum popliteum of the femur by fleshy fibres forming a fusiform belly (Fig. 3). The muscle fibres converged to a thin rounded tendon, which had its insertion into the medial margin of the lateral head of the gastrocnemius near its junction with the medial head. The tendon lay on the lateral side of the popliteal vessels and posterior tibial nerve. The muscle closely resembles the gastrocnemius tertius of Krause and the popliteus minor, the latter, however, gaining insertion into the posterior ligament of the knee-joint. The nerve supply was derived from the posterior tibial nerve. The condition was bilateral (Fig. 4). It is possible that some such muscle as this is the morphological equivalent of the palmaris longus of the hand.

CASE 5.—This abnormality introduces a controversial element. While demonstrating at Glasgow University I had a remarkably good specimen of the sternalis muscle, which occurred in a male specimen, aged 60, in whom the muscular system was well developed (Fig. 5). The muscle was bilateral and placed ventral to the pectoralis major. It took origin from the costal cartilages of the fourth to the seventh ribs and the adjacent half of the anterior surface of the sternum, a few of the fibres being in direct continuity with the fibres of the rectus abdominis. The muscular belly ended above in a stout tendon directly continuous

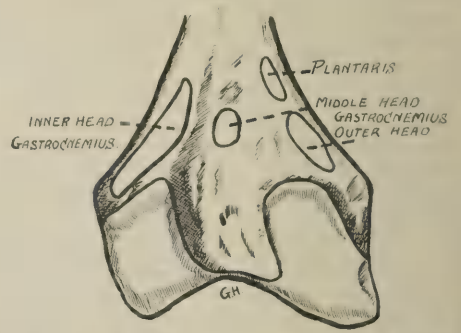
FIG. 3.



Case 4.—A small muscular belly or "middle head" of the gastrocnemius took origin from the middle of the planum popliteum of the femur in both legs.

with the sternal tendon of the sterno-mastoid, while a thin lateral expansion was attached to the medial end of the anterior surface of the clavicle. The right sternalis measured 4 cm. in breadth and 1 cm. in thickness, the left measuring 3·5 and 0·8 cm. respectively. The measurements were taken in the preserved condition. Unfortunately the nerve supply of the muscle was not definitely ascertained, although the muscle was pierced by the anterior terminal branches of the second to the sixth intercostal nerves. Since then I have observed four bilateral and three unilateral specimens at Glasgow, but in every case except one—the specimens being dissecting-room subjects—the possibility of a nerve supply from the external anterior thoracic nerve could not be excluded. In the exceptional case the muscle was observed early, and Dr. John Morton, lately demonstrator at Glasgow University, made an extremely neat and careful dissection. The specimen in this case was poorly developed, but there was no nerve supply from the external anterior

FIG. 4.



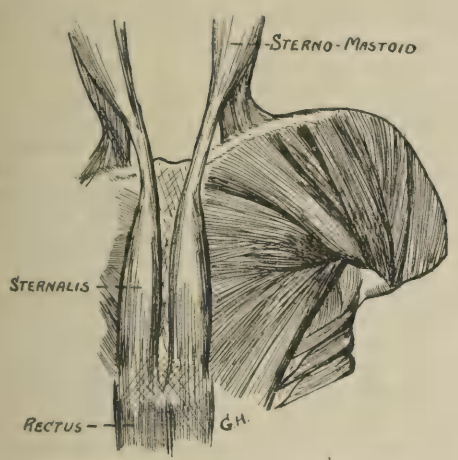
Case 4.—Lower end of the femur, showing precise site of origin of the "middle head" of the gastrocnemius.

thoracic. A twig from the terminal branch of the second intercostal nerve was traced for a distance of 1 cm. into the substance of the muscle, giving off numerous slender filaments.

Recently I have seen two bilateral and three unilateral specimens of the sternalis in the dissecting room at Singapore. In two cases the nerve supply was not definitely ascertained. In one, where the muscle was very poorly developed, the muscle fibres

ended in a thin aponeurosis, which passed laterally to blend with the fascia covering the pectoralis major, a few tendinous fibres crossing the middle line to blend with the aponeurosis of its fellow. In this case the muscle had a fine twig from the external anterior thoracic nerve. In the other two cases in which the muscle was observed early enough to permit of careful dissection for the nerve supply, the muscles were more definitely vertical in direction, and in each case they were continuous with the sterno-mastoid. In one specimen the third intercostal nerve before piercing the muscle gave off a fine twig which ended in minute ramifications in the substance of the muscle. In the other case the second and third intercostal nerves gave off similar twigs, which

FIG. 5.



Case 5.—Bilateral sternalis muscle in a male, placed ventral to the pectoralis major, taking origin from costal cartilages of fourth to seventh ribs and adjacent half of anterior surface of sternum. A few fibres were in direct continuity with fibres of the rectus abdominis; above the muscular tendon was directly continuous with the fibres of the sterno-mastoid.

ended in the substance of the muscle. Neither specimen had a nerve supply from any other source. The specimen figured in the diagram was the largest I have seen.

Considerable difference of opinion exists regarding the morphological significance of the sternalis muscle, and volumes have been written concerning it. To state the matter briefly, one authority holds that the sternalis is derived from the pectoralis major and shares its nerve supply. Indeed, when the muscle is present there is frequently a deficiency in the pectoral muscle. Others consider that it is part of the pubo-hyoid system, and therefore supplied by the intercostal nerves. In support of this theory is the fact in some animals the rectus abdominis extends to the first costal arch. I have seen the rectus extend as far up as the third costal cartilage in the human subject. Another authority considers it a part of the panniculus carnosus.

It is more than five years since I first directed my attention to the sternalis muscle, and I have seen most of the literature on the subject. From the specimens which have come under my notice it appears to me that there are two separate and distinct varieties of abnormality in this region. One variety, the sternalis proper, is supplied by the intercostal nerves and is morphologically continuous with the rectus abdominis. The other variety is developed from the pectoralis major and has a similar nerve supply to that muscle. This variety I propose should be called the sterno-pectoralis. Its nerve supply is a long slender twig from the external anterior thoracic nerve which pierces the pectoralis major to enter the deep surface of the abnormal muscle. It is a remarkable fact that this variety is present in 50 per cent. of anencephalic fœtuses.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOLOGY.

A MEETING of this section was held on Feb. 2nd, when the chair was occupied by Mr. SYDNEY SCOTT, President of the section.

SURGERY OF SUPPURATIVE AND CERTAIN NON-SUPPURATIVE AFFECTIONS OF THE LABYRINTH.

Sir WILLIAM MILLIGAN (Manchester) read a paper on this subject. He said the clinical picture presented by disease of the labyrinth varied with the segment of the internal ear involved—whether the static or the dynamic segment, or a combination of both. Disease of one segment did not necessarily mean involvement of the other too, therefore any surgical measure should be designed to cause the least interference with the non-infected or only partially affected area. When the cochlear segment was involved there was nerve deafness and persistent tinnitus; when the disease was in the vestibulo-canalicular system the patient had vertigo, disturbances of equilibrium, nystagmus, nausea, or even sickness. Purulent discharge of internal ear might result from the spread of a septic process from the base of the brain via the internal auditory meatus and the sheaths of auditory or facial nerve. Or extradural or subdural abscess might cause the eminentia arcuata to become eroded and afford an entrance for organisms into the superior semi-circular canal, and thus the infection might become diffuse. But the most frequent route was by way of the middle ear following erosion of a portion of its inner wall or capsule of the labyrinth. This he considered resulted mostly from chronic infective disease of the middle ear. When labyrinthitis was due to acute purulent otitis media it was practically always an induced serous labyrinthitis. In circumscribed labyrinthitis, he contended, the most frequent portal was an erosion of the external semi-circular canal. The diffuse form originated in the fenestra ovalis. In cases of tuberculous otitis media in which the disease had subsequently spread to the internal ear, the pars promontoria was frequently destroyed and so opened up a wide invasion portal. The organismal invasion, he thought, was a question of defective drainage, due to a number of causes.

Clinical Types of Labyrinthitis.

The types of labyrinthitis met with clinically were three: circumscribed, diffuse purulent, diffuse serous. A mere erosion of the lateral canal did not justify the diagnosis of circumscribed labyrinthitis, as the erosion might be quite superficial. Such an erosion should be left alone, reliance being placed on the drainage secured by some form of post-aural operation. Circumscribed labyrinthitis, though a real pathological entity, was almost undiagnosable clinically, the symptoms might mean the presence merely of serous œdema, the result of a septic focus in the vicinity. If there was more than an erosion—i.e., a fistula—what should the treatment be? The consensus of opinion was that it should be left alone. The differentiation clinically between the "open door" and the "protected territory" at present defied solution. The case was different in diffuse purulent labyrinthitis, with its profound loss of hearing, nystagmus, nausea, high temperature, &c.; this called for prompt and efficient surgery, as it was a dangerous condition owing to the likelihood of the infection reaching the base of the brain and setting up meningitis. Also, unless free drainage was carried out the function of the auditory nerve would be abolished.

In operating, Sir William Milligan's aim was to secure efficient drainage and yet conserve some functional activity. Wherever possible he left the cochlear segment alone as much as he could, freely

ablating the static segment, removing the pars promontoria, and leaving the columella alone. But if the hearing was destroyed in a case of severe infection, the freer the drainage the better. When a complete labyrinthectomy was required he preferred the "bridge" operation; the results in his hands were surprisingly good, the technical bugbear being the Fallopian aqueduct with its contained facial nerve. But with strong illumination and meticulous precision the nerve should escape injury. In 54 cases on which he had operated, any injury he might have done to the nerve had been permanent in none.

Non-suppurative Labyrinthitis.

The surgery of non-suppurative labyrinthitis constituted a more debatable and difficult problem. What, he asked, was the pathology of the pseudo-Ménière syndrome? Were these cases due to effusion into the internal ear, to atheromatous changes in the terminal blood-vessels of the part, or to a toxic neuritis? The cases were mostly met with among people who had mental strain and worry, and were characterised by attacks of severe vertigo, sickness, tinnitus, and progressive loss of hearing. Some had high, some low blood pressure, some had granular kidney, and others some digestive disturbance. But some otherwise healthy people were subject to sudden and violent attacks of vertigo, with sickness, tinnitus, and loss of hearing at irregular intervals. Sometimes depressants, such as bromides, gave relief, but the depression and incapacity required more heroic measures, and for years he had advised and carried out a partial or complete destruction of the labyrinth. He had performed it for this class of case 20 times without a fatality, with relief to the vertigo in all, but with disappearance of the tinnitus in only 40 per cent., though in half (20 per cent.) the noises were much relieved. The 40 per cent. of cases were probably central in origin. In opening up the canalicular system he saw no evidence of increased labyrinthine tension, and the structures appeared normal. He could say nothing on the pathology, as he had not seen a post-mortem specimen. He concluded that it was really a toxic neuritis, affecting at first the nerve proper, but later extending to the maculæ acousticæ, where it set up a vicious circle of static incoördination, oculo-motor, and gastric disturbance.

In conclusion, Sir William Milligan narrated some typical cases in which operation had been completely successful. Operation was only carried out after medical treatment had been persisted in for a period of from one to three years. He showed a number of slides illustrative of his thesis, some of which Mr. J. S. Fraser kindly sent him.

Discussion.

The PRESIDENT said Sir William Milligan was looked upon by his colleagues as a pioneer in labyrinthine surgery. Mr. C. E. West was inspired to operate on the labyrinth 20 years ago by Jensen's work in Berlin. The cases in which Mr. West and he did the operation were mostly those in which disease was being followed to its source in the course of a radical mastoid operation. Errors might have been made by operating on patients who, because they were seized with vertigo, were assumed to have disease within the labyrinth. Most would agree that in some cases the labyrinth was needlessly destroyed. But there was a class of case in which the infection of the middle ear was so virulent that the organism gained entry into the internal ear. In a man aged 60, with symptoms of otitis media, on whom the speaker operated, death occurred in 11 hours, and the patient had already got meningitis. In deciding whether to operate or not, a careful clinical examination was of the utmost importance.

Sir CHARLES BALLANCE said all would agree that there were certain cases which should not be operated upon, but that was so in the evolution of every fresh operation; and the operation had been done because the surgeon felt it to be his duty to carry it out. The operation described by Sir William Milligan should certainly be done in suppurative labyrinthitis. Failing the establishment of free drainage, the patient would certainly die. He (Sir Charles Ballance) thought the most important factor was to have a very free area of bone exposed behind the facial canal. He saw Jensen operate on labyrinth cases in Berlin in 1900 and 1901; he was an able operator, but so quick that onlookers felt trepidation as to possible unintentional injury. The speaker considered that this region should be operated upon with extreme care and deliberation; no disaster need then be feared. With regard to the other group of cases, the non-suppurative, he agreed that the condition seemed to be a toxic neuritis, and that there was, in the majority of the instances, no obvious change in the internal ear. In the cases narrated by Sir William Milligan the operation was not only justifiable, but urgent. In some patients the nerve could be divided behind the internal auditory foramen. It was easy to expose the cerebellum and press it back by means of dry, sterilised marine sponges, as used by Sir David Ferrier. In suppurative disease it was not always necessary to take away the capsule of the cochlea.

Dr. ALBERT A. GRAY (Glasgow) commented on the rarity of non-suppurative cases in children under 12 years of age. In Ménière's disease he thought the symptoms were due not so much to high or low inter-labyrinthine pressure as to a sudden change from one to the other; that was probably why it occurred in people who were overworked. He agreed that a number of cases might be toxic.

Dr. P. WATSON-WILLIAMS spoke of the necessity of excluding sinus disease.

Mr. MUSGRAVE WOODMAN agreed that simple conditions should be eliminated before operative treatment was entertained. He narrated a case in which a man said he was incapacitated by attacks of vertigo and tinnitus. He was found to have a tight block in his Eustachian tube. A fine bougie was tightly gripped at the isthmus. On repeating this a month later, the bougie passed fairly freely, and since then the attacks of giddiness had ceased. But there were some cases of non-suppurative labyrinthine trouble on which operation should be done. He related a case of the kind in which he performed free drainage, and the patient, a nurse, was able to resume her occupation.

Mr. E. D. DAVIS related a case in which a patient with violent nystagmus lasting 12 months had lumbar puncture performed and got well after it. She was very highly strung. A widow who was working very hard and experiencing much anxiety had violent vertigo, sickness, and nystagmus, with loss of confidence. The passage of an Eustachian bougie cured these symptoms. There seemed to have been bad results from division of the auditory nerve in the hands of several surgeons, due to severe hæmorrhage.

Mr. G. J. JENKINS agreed that many cases were diagnosed as disease of the labyrinth when there was only a middle-ear affection. Two children with very pronounced labyrinthine symptoms were cured by the removal of enlarged tonsils and adenoids. Owing to the lack of a specimen from a non-suppurative case, it was difficult to obtain a clear idea of the pathology of pseudo-Ménière's disease.

Mr. L. COLLEDGE said the chief question in a desperate case was as to what operation should be done. There was a likelihood that an increase of intracranial pressure might lead to symptoms. In some cases it was simpler and safer to do a cerebellar decompression operation than to open the labyrinth.

Dr. W. S. SYME said he always put the nasal condition of patients with these symptoms right before considering the question of operation. In only two non-suppurative cases had he opened the labyrinth. In acute cases he approached the question of operation warily.

Reply.

Sir WILLIAM MILLIGAN, in reply, said he also saw Jensen operate in Berlin, and he agreed with Sir Charles Ballance that he did his operations in this confined region far too rapidly. When the anæsthe-

tist pointed out to the operator that the facial nerve was twitching, the sharp reply was, "It does not matter." The facial nerve was paralysed before the patient left the table. He did not agree with Sir Charles Ballance that the cases were more easily approached through the posterior fossa. He had never found that lumbar puncture brought any permanent relief to the cases he had described. Years ago he tried decompression of the posterior fossa, but had now given it up. He emphasised the point that operation was not done by him until a very careful attempt had been made to exclude other conditions, and until medical treatment had been given a good trial.

A number of instructive cases shown by members were discussed.

Reviews and Notices of Books.

SYNOPSIS OF MIDWIFERY.

By A. C. MAGIAN, M.D., Gynæcologist to the Manchester French Hospital. London: William Heinemann (Medical Books), Ltd. 1923. Pp. 245. 8s. 6d.

THERE must be many practitioners so fully occupied that they have not leisure to read ponderous text-books on obstetrics, and yet are anxious to keep abreast with current thought and teaching. To such and to the senior student who wishes to refresh his memory before the examination ordeal, we can with confidence recommend Dr. Magian's little volume. As the title suggests, the book is a synopsis of the leading facts and principles of treatment, and in its compilation the author has freely consulted the writings of most British authorities on the subject. In the space of 245 small pages Dr. Magian has managed to compress a wonderful amount of material. The style, although somewhat didactic, is not abrupt, and each of the 31 chapters contains sound teaching.

We recognise many well-known precepts, and with most of the teaching we are in complete accord. There is very little debatable material, and such as is present must be attributed to the works consulted rather than the author. Progress moves apace, and for this reason it is difficult for any book which relies for its information upon its predecessors to be absolutely up to date. For example, there is no reference to Eardley Holland's recent work on the causes of stillbirth, or again in the chapter on anæsthesia to the advantage of spinal anæsthesia in Cæsarean section and in labour complicated by mitral disease. Eclampsia and its treatment, on the other hand, is well discussed, and the chapter on Forceps is particularly good. It contains what is necessary without any undue padding, and if the advice given is acted upon, the practitioner can be satisfied that he is acting up to ideals.

The book, like other synopses, is not intended to replace or add to the number of standard obstetric text-books, and is not suitable for the junior student. The senior man, however, will find it a very useful "refresher" and can be assured that the information he finds within its pages is sound.

PREVENTION OF DENTAL CARIES AND ORAL SEPSIS.

Third edition. By H. P. PICKERILL, C.B.E., M.D., Professor of Dentistry, and Dean of the Dental School, University of Otago. London: Baillière, Tindall and Cox. 1923. Pp. 340. 18s.

WHEN the first edition of this book appeared in 1911 it was generally recognised that Prof. Pickerill had made a notable addition to dental literature. It displayed original research and a determination to take nothing for granted. Instead of publishing various researches as they were completed in different journals, he withheld them until their appearance in this book. Thus the world of dentistry, not being in any way familiarised with the nature of his investigations, was the more prepared to be impressed by the amount and quality of original research embodied therein.

In form and matter this edition does not differ materially from the first, though both additions and emendations have been made. One feels that there is a certain risk in publishing successive editions of a book which is a record of personal research; the title-page may be dated 1923, but the work itself dates from 1911, and has lost some of its freshness. Prof. Pickerill's work has not passed unchallenged, but we do not find any serious consideration of investigations which have appeared since this book was first published. F. P. Chillingworth, for instance, has attacked both the chemical methods used by Pickerill in his investigation of salivary secretion, and his conclusions that it varies according to the food. This work appeared in 1922, and gives several references to earlier work directly dealing with Pickerill's results. The fact that the author does not take into account the work of Chillingworth and others rather lessens the value of his conclusions from the point of view that they still hold good without modification 13 years after their first publication. The section on the bacteriology of the mouth does not seem to go beyond the work of K. Goadby. In 1911 this was inevitable, but to-day we are in possession of the work done by P. Howe in 1917, and the still more important investigation of McIntosh, James, and Barlow in 1922, both of which make Pickerill's conclusions on this subject of less account. But many of the researches have been generally accepted and confirmed by other workers, that on enamel, for instance, has added another chapter to our knowledge of this complicated tissue. It would have been difficult perhaps to have added anything to this section of the book, so sound in plan and execution.

It is an encouraging sign that a book like this, which is not an ordinary text-book, but is crammed full of original work requiring close reading, should reach a third edition. Even if it has lost its first youth, it still remains a stimulating and suggestive piece of work. Its influence on dental thought, both in this country and abroad, has been considerable, and dental science is a debtor to Prof. Pickerill.

COLLOIDS.

Manuel de techniques de physico-chimie et spécialement de chimie des colloïdes; à l'usage des médecins et des biologistes. By LEONOR MICHAELIS. French translation by H. CHABANIER et C. LOBO-ONELL. Paris: Masson et Cie. 1923. Pp. 204. Fr.12.

WE have reviewed the second German edition of this work, of which this is an excellent translation into French. All that we said of the German original was to its credit, and applies equally well to the present translation, which will be welcomed by those who are less familiar with German than with French. A large sale for this volume can be predicted.

A MANUAL OF PSYCHOTHERAPY.

By HENRY YELLOWLEES, M.D., F.R.F.P.S. Glasg., M.R.C.P. Edin., Medical Superintendent, The Retreat, York. London: A. and C. Black. 1923. Pp. 247.

DR. YELLOWLEES belongs to no particular school and gives an impartial account of current psycho-pathological theories. He accepts the psycho-analytical ætiology, but regards persuasion and suggestion, in which he includes the formal use of hypnotism, as of more immediate value than analysis. Hypnotism, however, he prefers to use as a means of aiding the return of lost memories, the process of integration thus carried out accomplishing more than the mere removal of symptoms by suggestion under hypnosis. The chapters on dream analysis and psycho-analysis briefly outline the subject, but are not intended as sufficient guides to their practice. Those on psycho-therapy in general practice point out the need for an

understanding of the unconscious processes described in previous chapters and contain sound advice on elementary and important points.

Concerning "nervousness" Dr. Yellowlees writes as follows: "With a little understanding and assistance, most patients who use this word will reveal themselves as cases of obsessional neurosis, or of some anxiety state, although it may be hard to put a diagnostic label upon such a case until after the patient's confidence has been fully gained in several interviews." The application of this teaching, simple as it appears, will reveal a wealth of clinical material that should tempt the practitioner into further study. As a guide to the objects of this study Dr. Yellowlees's admirable book affords a useful and practical introduction.

ZOOLOGY.

Outlines of Medical Zoology. By R. W. HEGNER, W. W. CORT, and F. M. ROOT. London and New York: Macmillan Company. 1923. Pp. 175.

THIS rather slender handbook of Medical Zoology has grown out of a publication which appeared in 1921, entitled "Diagnosis of Worms Parasitic in Man." It is naturally fuller than its progenitor and therefore to that extent more useful. But it is not a treatise upon the general zoology of parasites; it is a list of those known in man with sufficient diagnoses to aid public health officers, students, and physicians. For such readers it should prove a convenient epitome of much that it is necessary to determine in identifying a parasite. Identification is also rendered much more easy by a few plates illustrative of protozoan parasites, such as malaria, and of salient anatomical characters of eggs of worms and various parts of insects and mites. In connexion with their association with or merely as carriers of certain diseases the authors explain many of the methods in use for collection or preparation of protozoa, worms, and arthropods, which form the parasitic groups dealt with. All this information is undoubtedly strengthened by a reasonable list of books by different authorities, and a selection of journals which deal with parasitological matters. The usefulness of this handbook is enhanced by a fairly full index, in which references to pages on which a figure occurs are printed in heavy type, and names of investigators as well as animals are to be found.

A Manual of Elementary Zoology. Fourth edition. By L. A. BORRADAILE, Sc.D., Fellow and Tutor of Selwyn College, Cambridge. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 671. 18*s*.

Elementary Zoology for Medical Students. By L. A. BORRADAILE, Sc.D. Same publishers. 1923. Pp. 378. 10*s*. 6*d*.

THESE two volumes are hardly two separate works; for the smaller, which is intended only for the student of medicine, is practically an abbreviation of the larger volume from which the bulk of its pages are drawn. It has, however, a new introductory chapter. The Manual has now reached its fourth edition, having been originally published in 1912, and the author is to be congratulated upon its long life. The addition of two new chapters upon the sponges and echinoderms respectively may be noted, and a revision of statements and slight alterations in respect of mammalian embryology and the physical properties of protoplasm are to be found. A statement of this kind is made in the author's preface, and shows how fixed and almost axiomatic the general body of facts dealt with in an elementary text-book tends to become. The types of animals selected for detailed study are so well-known that it is almost difficult to fall into error. Furthermore, the continued and widely spread study of zoology throughout the world has brought before us a vast amount of facts relating to other animals than those commonly selected as types, and this has been confirmed again and again, and now constitutes a reliable collection of information. To such accumulations or conversant authorities any writer of a text-book to-day should apply for assistance or confirmation. Thus, the author, himself best known as a student of certain crustaceans, quotes the names of others who are well known in other regions of zoology.

AIDS TO PHYSIOLOGY.

Second edition. By JOHN TAIT, M.D., D.Sc., late Lecturer in Experimental Physiology, Edinburgh University; and R. A. KRAUSE, M.D., D.Sc., late Lecturer in Hygiene and Physiology, College of Hygiene and Physical Education, Dunfermline. London: Baillière, Tindall and Cox. 1924. Pp. 255. 3*s*. 6*d*.

IT must not for a moment be supposed that the authors intend this small work to be used by students as a text-book of physiology; it is not a text-book, and can never be regarded as one. Whether such small and compressed books are of any real value is a thing best decided by students themselves. Judging from their sale, it would seem that they have a certain field of usefulness, and in so far as small books of this description are used by students for purposes of revision only, there is nothing to be said against them. This present volume is excellent in its way, is accurate and up to date, and puts the subjects in the smallest possible space. We should only object to it, and then most violently, if students were to attempt to learn all their physiology from it, for such efforts would be attended with certain failure. This little volume, like its similars, should prove valuable in those trying weeks which immediately precede an examination.

JOURNALS.

QUARTERLY JOURNAL OF MEDICINE.—The January number contains the following articles: Acute Myelocythæmia and Chloroma, by Alexander Goodall and W. A. Alexander. Four cases of acute myelocythæmia are recorded, the first being a typical example of the disease and the last of chloroma, whereas the third shows features which are intermediate between the two conditions. Less than 100 cases of chloroma have been published to date, and the third of the series here recorded, representing the intermediary stage, is regarded as unique. The disease had a rapid course in every instance, varying from two weeks to three and a half months. The total white cell count was relatively low, and the spleen was not greatly enlarged. The opinion is expressed that leukæmia is the result of infection, and that the process is of the nature of a tumour growth. The article is illustrated by two plates, showing the macroscopical and microscopical appearances.—An Investigation into the Pathogenesis of Disseminated Sclerosis, by D. K. Adams, J. W. S. Blacklock, E. M. Dunlop, and W. H. Scott. A clinical description of the early symptoms is first given. Examination of the cerebro-spinal fluid shows that whereas the Wassermann reaction is negative in disseminated sclerosis the colloidal gold test gives a positive reaction. It has been disputed whether it is possible to produce nervous disease in rabbits by the injection of the cerebro-spinal fluid obtained from patients suffering from disseminated sclerosis. The authors inoculated 16 rabbits with cerebro-spinal fluid obtained from nine patients, and produced nervous symptoms in five of the rabbits, with fluid from five of the nine patients. Injection of citrated blood from eight patients produced nervous symptoms in three instances. Emulsions of the central nervous systems of rabbits showing nervous symptoms produced, on inoculation into other rabbits, nervous symptoms in two of the 11 tested. In all over one-third of the rabbits inoculated developed nervous symptoms, whereas control rabbits inoculated with blood and cerebro-spinal fluid from normal individuals and those

suffering from other diseases showed no effect. Spirochætes were found in some of the inoculated animals. Early diagnosis and treatment with the salvarsan group of drugs is recommended. Two plates are included, illustrating the nervous symptoms produced in the rabbits, and the microscopical appearances of the organs of the infected animals.—Diastase Determination in Urine and Blood as a Method for the Measurement of the Functional Capacity of the Kidney, by D. D. Stafford and T. Addis. The authors first describe their methods for estimating the amount of diastase in the blood and urine. An investigation was carried out on a series of cases of Bright's disease. It was found that the concentration of diastase in the plasma and the urine, and the rate of diastase excretion did not afford any indication of the extent of the renal lesion, as judged by the rate of urea excretion and the urea concentration in the blood.—The Adenoid Child: A Histological and Clinical Study, by Lucy Wills and Joan Warwick. As the result of a clinical and histological study of adenoid children, the authors conclude that a relationship exists between the type of adenoid enlargement and the configuration of the child. In inflammatory adenoid lesions the figure and bodily posture is normal, whereas in adenoid hypertrophy there is muscular hypotonus with marked lordosis and a pendulous abdomen. Chest deformities are found in both groups, they are probably due to rickets. A correct diagnosis of the histological character of the adenoid enlargement was made on postural grounds in between 83 and 88 per cent. of cases. Plates illustrating the configuration of the children and the histological appearances of the adenoids are included.—Arthropathia Psoriatica, by Archibald Garrod and Geoffrey Evans. The association of joint lesions with psoriasis has been described by many authors. Three cases are here recorded, in two of which a peculiar condition of intermittent hydrarthrosis occurred. Menstrual irregularity was also a prominent feature.—The Operation of Cardiolysis, with a Description of Two Fresh Cases and an Analysis of the Literature, by Geoffrey Bourne. This article opens with an account of the physical signs and mechanics of adherent pericardium. The indications for cardiolysis are then described, the chief of which is heart failure with pericardial adhesions, the contraindication being a severe progressive rheumatic lesion. Two cases operated upon by Mr. Joseph Adams are described, in both of which there ensued a considerable degree of amelioration of symptoms. The article concludes with an abstract of 23 cases from the literature.—Experiments on the Ætiology of Chronic Infection of the Spleen, by Alexander George Gibson. In a previous communication to the *Quarterly Journal* (1914, vii., 153) the author detailed some observations on cases of splenomegaly of obscure origin, in which it was suggested that infection with a streptothrix might be the ætiological factor. Further experiments have now been performed with a streptothrix isolated from the spleen of a patient who had suffered from recurrent acholuric jaundice. Ten monkeys were inoculated, and all showed symptoms of disease. From three of the animals the streptothrix was recovered and grown in pure culture. It is therefore claimed that Koch's postulates have been complied with, although it does not appear clear that the inoculated monkeys suffered from the same disease, as the patient from whose spleen the streptothrix was isolated, for in only one monkey was the spleen enlarged, and in none was the fragility of the red cells increased.—Critical Review: Sepsis as a Cause of Lymphocytosis, by H. Letheby Tidy. Sixteen cases of lymphocytosis possibly associated with sepsis have been collected from the literature published from 1907 onwards. An analysis of these is given, as a result of which the author concludes that there is no evidence that sepsis produces lymphocytosis.—The journal concludes with an account of the proceedings of the annual general meeting of the Association of Physicians of Great Britain and Ireland held at Edinburgh in 1923.

JOURNAL OF INDUSTRIAL HYGIENE. November, 1923.—The effect upon output of alternating occupations is discussed by J. M. Baumberger. He presents a study of output hour by hour in the processes of glass gathering, the spin-top lathe operation, and recessing gears. In the first, work is only carried on for a short time and then is alternated for another process, in the last two the operation is continuous through the shift. The author finds that a closer approach to maximum working capacity occurs when occupation is alternated, and suggests that in this way increased output might be obtained in many industries.—C. K. Drinker contributes an article on the present status of resuscitation in cases of electric shock and of carbon monoxide poisoning. He finally concludes that the Schäfer method of resuscitation is at once the simplest and most effective method, and decides against any specially constructed apparatus, except in unusual circumstances. For this reason he does not favour the oxygen-carbon-dioxide method.—E. L. Collis writes a statistical article dealing with the general and occupational prevalence of bronchitis, in which he discusses its relation to phthisis and to pneumonia. He finds that the mortality from bronchitis has been falling even more rapidly than that from phthisis, while in contra-distinction the mortality of pneumonia has been rising. Climatic conditions and atmospheric pollution are considered to be the main causative influences affecting bronchitis, while no evidence is found that it spreads as does phthisis through infection. Bronchitis is held to be a disease of chronic traumatic origin associated with irritating atmospheric conditions.——The number dated December, 1923, contains an address by C. E. Ford, President of the American Association of Physicians and Surgeons, which contains matter of some interest. He points to the strategic position occupied by the industrial physician with regard to many public health problems, and places within his purview such things as infant welfare and pre-natal care as being subjects inextricably bound to the industrial future of the nation. He holds that merely by applying present knowledge the average length of life could be readily extended to 65 years, and shows how low wages result in high rates through increased sickness. The author gives definite statistics to support his case.—J. N. Basin deals with the prevalence of medico-legal aspects of sprained back, a common condition seldom treated scientifically. The author holds that in each case there is a solution of tissue continuity by tearing soft tissues, joint luxation, and occasional sprain fracture in the lower spinal region. He strongly advocates a pelvic girdle support to prevent "labour back" for all manual workers. Accurate diagnosis and early treatment are held to be necessary to economic recovery.—L. R. Thompson and D. R. Brundage discuss the way in which sick benefit associations may profitably engage in the work of preventing disease. These associations possess information as to the extent and locality of sickness, which may vary from 151 cases per 1000 in one industrial plant to 62 cases in another. Only by following up such statistical information can the cause of undue sickness be accurately diagnosed. The authors put forward an unanswerable case for the need for morbidity statistics.

LEAGUE OF NATIONS HEALTH ORGANISATION.—We have received four pamphlets, prepared for the Society of Medical Officers of Health in connexion with the visits of foreign public health officers arranged by the Health Organisation of the League as part of a scheme for interchange of public health personnel, financed by the Rockefeller Foundation. The first pamphlet contains Notes on Public Health Organisation in England, by Dr. Charles Porter. The other three, by senior officers of the Ministry of Health, are entitled "English Port Sanitary Administration," by Dr. R. J. Reece; "Administrative Control of the Purity of Food in England," by Dr. A. W. J. MacFadden; and "Anti-Tuberculosis Measures in England," by Dr. F. J. H. Coutts. These pamphlets illustrate medical intelligence and propaganda which is very appropriate to a Government office, and represent the sort of handy up-to-date information which the Ministry of Health itself might usefully publish for home consumption.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

VI.—ACTIONS FOR DAMAGES: ERRORS OF DIAGNOSIS.

BY HUGH WOODS, M.D., D.P.H.,
GENERAL SECRETARY, LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

Beware
Of entrance to a quarrel; but ....
—*Hamlet*, Act I. Sc. 3.

ACTIONS for damages are rarely brought against medical practitioners in respect of alleged deliberate wrongdoing. Damages are claimed in the great majority of cases on the ground of negligence, or want of skill, or both. Want of skill is not often put forward as the main ground for claiming damages. To substantiate such a claim it must be proved that the skill exhibited was below that which any ordinary individual of the practitioner's standing in his profession would be reasonably expected to possess. A jury is not readily inclined to believe that a properly qualified doctor has not the average skill that all doctors are assumed to possess. If he has caused damage to his patient they are much more ready to believe that, while he had skill enough to avoid it, he did not take the trouble requisite for this purpose. The defence against a claim for damages consequently depends almost always on the evidence available in disproof of charges of negligence on the part of the doctor. Treatment, whether medical or surgical, is often unsuccessful. Patients die, or get worse instead of better, and the medical attendant may be blamed. In fact, with some people, it seems to afford them relief if they throw the blame for their misfortunes on someone else, and recent legislation, such as the Workmen's Compensation Act, appears to have created an impression that misfortunes or accidents should be alleviated by compensation at the expense of someone other than the sufferer under almost any circumstances.

Precautions Against Accusation of Negligence.

To obtain compensation from the medical attendant charges of negligence are readily trumped up, and they are often difficult to rebut. It is easy enough after the event to find fault with what has been done, and to contend that things which were left undone would have had far better results. Almost any line of treatment is open to criticism, and medical evidence is too often available in support of criticism more or less captious or unfair. Hence it becomes a matter of ordinary prudence for doctors to adopt precautions against accusations of negligence in their treatment of patients. Preventive precautions are, of course, best, but these will frequently fail, and it is therefore necessary to be prepared to defend oneself successfully when attacked. It is a mistake to suppose that the most careful practitioner will be immune to attacks founded on allegations of negligence. Claims for alleged negligence, put forward without any just foundation by dishonest or foolish claimants, may nevertheless be very difficult to meet satisfactorily. Conscientious care in all cases is a matter of duty as well as of prudence; but it is also advisable to avoid all appearance of carelessness and to remember that the adoption of routine precautions, the making of detailed examination, the employment of tests, and in general the outward indications of care, assume an importance quite beyond their due when a case goes into court. Especially important is the evidence of little details of the procedure adopted in arriving at a diagnosis when an error has been made, as will happen with the best of physicians or surgeons. A stupid mistake made in diagnosis after a punctilious observance of all the appropriate rules for arriving at an accurate diagnosis is much less likely to lead to legal disaster than the making of a mistake which could hardly or at all have been avoided, if any procedure recognised as advisable has been omitted, even though the practitioner has quite reasonably considered it unnecessary or useless.

X Ray and Bacteriological Examinations.

Consequently, in the case of injury of bones or joints, it will be a great advantage to the surgeon if an X ray examination has been made; and if such examination has been omitted and the exact nature of a fracture or dislocation has not been detected the omission will be described by plaintiff's counsel as gross neglect, and to it he will attribute any failure to attain a perfect result, even though it be a case in which permanent deformity was highly probable. Again, if a medical attendant has failed to detect a disease such as tuberculosis or diphtheria, it will be unhesitatingly assumed by plaintiff's counsel, and quite likely believed by the jury, that a bacteriological examination would have ensured an accurate diagnosis. It will be difficult, on the other hand, to prove that such an examination would not have been desirable or conclusive. A verdict of negligence, and an award of damages, is only too likely to result even though there be no reasonable grounds for the belief that a more precisely accurate knowledge of the conditions would have meant better treatment or a more satisfactory result.

Sharing the Responsibility.

It may seem, then, that it should be an absolute rule that such examinations should without exception be insisted on in the interests of the medical attendant quite apart from those of the patients. There are, however, in many cases serious difficulties in the way of adopting this as a fixed rule. Patients and their relatives often object to the cost, and ask if the doctor thinks such examination really necessary. Unfortunately, the fact that the doctor feels quite sure of his diagnosis, without special methods of examination, does not preclude the possibility of error, and the fact that any examination at all likely to be made will not alter the treatment does not make the doctor's position safe if an error is subsequently detected. In remote country places the difficulty in the way of an X ray examination is sometimes very serious, and it may be impossible to arrange for it without prohibitive expense or the risk of ill consequences from the conveyance of the patient to a place where such examination is practicable. In these instances the responsibility should be laid as far as possible on the patient or the responsible relatives. The desirability of the examination should be clearly explained and any danger or expense that will be involved should also be pointed out. This should be done either in writing or in the presence of trustworthy witnesses, so that in the event of a claim for damages it can be incontestably proved that the patient was fully informed and accepted responsibility. Otherwise, the medical attendant may find his truthful assertions positively denied, and it may be supposed that he is only inventing excuses to justify his own negligence.

In some cases, when the doctor is convinced that unnecessary risk of a bad result will be run if the examination he recommends is not carried out, it may be advisable to refuse to continue in charge if his advice is not followed, but, of course, if the extreme step of withdrawing from a case is decided upon, proper care should be taken that the patient shall not be exposed to any risks thereby.

ARUNDEL AND DISTRICT COTTAGE HOSPITAL.—A satisfactory financial situation was reported at the annual meeting of the governors on Jan. 31st. The receipts for 1923 totalled £1422, including £613 from subscriptions £292 from hospital fees, and £300 from the pageant committee. The latter had been invested, and the balance at the bank increased from £210 to £283. The net expenditure was £1033, and the net revenue, £1121 18*s.* 8*d.* It will be remembered that in 1917 the town took over the hospital from the Duchess of Norfolk, and the executive committee assumed financial control, with Sir William Bird as President.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 9, 1924.

HOUSING AND HEALTH.

THE first Minister of Health, Dr. ADDISON, was a medical man, and it was, we believe, with the approval of the Administration with which he was associated that he embarked upon a campaign for setting right our lamentable housing conditions, making it the reason and basis of his official life, and considering that such action was fundamental to the duties of his office. The fact is well-known, though its reasons are not correspondingly clear, that the great activities thus set in motion had to be suspended; Dr. ADDISON failed to obtain the support of his colleagues for his objectives, and thereafter housing questions have not taken so prominent a position in the programmes of succeeding Ministers of Health. Yet all medical men know that whoever presided over the Ministry must have been aware of the vital importance to the health of the nation which is implied in housing reform.

The new Minister of Health, Mr. JOHN WHEATLEY, has done well, therefore, in selecting the housing question as the subject for his first speech to his constituency upon his appointment, when he took the bold course of confessing that he was not in a position to say what the Government's policy is or would be. We say bold, for it is possible to be discreet and valorous simultaneously, and to require more courage to confess to the discretion than the valour. For medical men Mr. WHEATLEY'S acknowledgment that he was taking thought of the undoubted difficulties in his path before deciding how to meet them, implies a promise that he will face those difficulties by ascertaining their sources and estimating their importance. We hope that such is his intention, for then he may arrive at a course of therapeutics founded upon the origins of the evils rather than upon their symptomatology. He will, it seems to us, lay truly the foundations of an enormous task, if he can clear away from the public mind the many misunderstandings which impede all in whose hands the actual provision of adequate housing must lie, among whom the whole of the medical profession, and not only the branch of that profession officially attached to his bureau, must be included. Medical men, finding in bad housing conditions the origin or the fomenter of disease, feel helpless in their attempts towards remedy as long as it is idle for them to make representations for housing reform; and yet it is no reproach upon any public authority to confess itself unable to carry out such recommendations as are made. And these conditions will remain so long as political animus leads one school of thinkers to attribute the present inertia entirely to the intention of a certain class to exploit the interests of the nation for private profit, or another school of thinkers to see an alleged insistence by trade-unions upon monopolies as the sole source of the evil. The health of the people is not a political question but a national one, and, where the right course to be taken cuts across the political views of the Government or of any opposing party, the party views should not be maintained, and no party capital should be made out of the acquiescence of any section of Parliament to a conjoint scheme containing certain elements of which, as a party, they must disapprove.

While the policy of the new Minister of Health is to commit himself for the present to no particular policy, the inertia of the past is not to continue. For we understand that there is a programme to provide for 120,000 houses in the first year, the work to develop in proportion as labour and material are obtained; the former will have to be guaranteed as continuous, and the latter subjected to equitable rates of purchase. It will be as natural for a Minister of Health to turn to the medical profession of the country for assistance as it is natural for us to point out the prudence of the course. It should be and would be possible to obtain an expression of sound medical opinion upon the meaning of overcrowding, and upon the circumstances which would affect any statistics of population in this regard. Similarly medical opinion, if collected from widely separated sources and properly tabulated, would be of the highest practical use not so much in advising upon new construction as in suggesting how to transform wisely the large number of existing buildings where their condemnation would be wasteful while their application to their old purposes is lost. Another advantage of medical coöperation would be the revivifying of the powers possessed by sanitary authorities of inspecting premises with a view to their fitness for habitation: these powers are possessed but under war conditions they fell into abeyance. If buildings were transformed in consonance with medical ideas it would be an obvious responsibility upon the medical profession to see that the work was not only well done but continued to provide decent and suitable accommodation. We are not suggesting that the Minister should begin the campaign by summoning medicine to his assistance, but sooner or later he must ask medicine to stand by him in his task, and we trust it is not merely prejudice which makes us think that the sooner the invitation were given the better. In the medical profession the Minister of Health has a body of highly trained men distributed, even though unevenly, throughout the country, a large majority of whose members are personally acquainted with the results of foul or scanty housing in various environments, and a distinguished fraction of this profession are officials in his own department while members of the great medical constituency. When schemes are set in hand, as the labour and material are found, medical men should be made familiar with those schemes, when various experiences at different centres would almost automatically become common property through the medium of the medical officers of health.

SURGERY OF THE SPLEEN.

A RECENT discussion at the Royal Academy of Medicine in Ireland raised the questions when and how the spleen should be removed. Operative methods in the treatment of splenic diseases do not bulk largely in the practice of the average surgeon. There are several reasons for this. The physiology of the spleen is but imperfectly known, though it would appear to be important judged by the very profuse blood-flow through it, which is assisted by rhythmical contraction of the organ itself. This ignorance of true function has prevented the development of

surgical measures devised to influence its normal activities. It is to be noted that such surgical operations would not necessarily be performed upon the spleen itself, though should they be, the possible field of intervention is very strictly limited by anatomical conditions. Surgical therapy of the spleen resolves itself almost exclusively into removal of the organ. There are a few exceptions: occasionally a suppurating cyst or abscess requires a simple incision, whilst now and then it has seemed advantageous to perform splenopexy when the viscus has become abnormally mobile. Even here, however, in the general consensus of surgical opinion removal is preferable to fixation. A discussion of the surgery of the spleen, then, concerns itself chiefly with the consideration of the advisability of excision in certain conditions of injury and disease. Splenectomy has been performed more often for traumatic rupture than for any other affection, rupture being the commonest cause of severe intra-abdominal hæmorrhage after injury. There may be, as an associated thoracic lesion, a fractured rib, itself the actual lacerating agent, or the rib may have torn the lung and so confuse the clinical picture. It is important to remember that the intra-abdominal hæmorrhage is sometimes delayed. An interval of as long as nine days has been recorded between the time of the injury and the onset of clinical signs of internal hæmorrhage. In such cases it is supposed that either a laceration has been plugged with clot or the primary hæmorrhage has been subcapsular. A cough or other sudden movement of the patient dislodges the clot or ruptures the thin, distended splenic capsule when the catastrophe occurs. After removal of the spleen, it has been suggested recently that the blood effused into the peritoneal cavity should be returned to the circulation of the patient. Spontaneous rupture occurs in malaria and during the course of some infective diseases, as typhoid and even puerperal fever. Surgical treatment is then urgently needed, but fraught with great risk.

There are a number of diseases in which splenomegaly occurs and in which splenectomy has been tried, but until recent years with only very indifferent success. Particularly as a result of careful work in the Mayo Clinic, the indications for splenectomy in these diseases have been formulated on a statistical basis, the only possible basis in the pathological obscurity which at present enshrouds them. In that vaguely defined disease, splenic anæmia, some have claimed that removal of the spleen has brought about complete cure. Whether this can be substantiated is open to doubt, but certainly after splenectomy improvement nearly always takes place, and the measure should be recommended in view of the hopeless outlook with medical treatment alone. At the Mayo Clinic the operative mortality in 71 cases was 12·6 per cent. In pernicious anæmia the ultimate results are not so good, but the mortality was brought down to less than 6 per cent. (in 54 cases) and the patients live, on an average, two and a half times as long as non-splenectomised patients. In this disease the removal of suspected foci of infection is essential, and in all these cases blood transfusions are almost indispensable if we are to obtain the above happy outcome in a high percentage of operations. In the different forms of leukæmia splenectomy has always been regarded as exceedingly fatal. Adhesions are usually present and abundant; their separation leads to hæmorrhage, which is not easily controlled. At the Mayo Clinic this difficulty has been overcome by a preliminary treatment with radium, by which the spleen is made to diminish in size temporarily. In this way 29 splenectomies were performed for myeloid leukæmia, with only one death; the lives of these patients were certainly prolonged by the operation. In hæmolytic icterus of the acquired type complete cure results from splenectomy, and the operation should be advised; it should never be done in the familial type, as such patients may live to an advanced age and suffer no inconvenience from the condition. Finally, in Gaucher's disease splenectomy has not been found to be very effective.

To sum up, it will be seen that a degree of alleviation, in some cases quite great, can be brought about in certain grave diseases associated with enlargement of the spleen by its removal. The operation, however, is always hazardous, and should not be undertaken except in favourable surroundings and after careful preparation of the patient, by blood transfusion as a rule, by the therapeutic application of radium sometimes.

THE FAT-STANDARD OF COWS' MILK.

EVER since the passing of the Sale of Food and Drugs Act of 1875, there has been discussion as to what composition should entitle cows' milk to be regarded as genuine. Twenty-five years ago a presumptive standard was set up, to the effect that, unless the milk contains 3 per cent. of fat and 8·5 per cent. of non-fatty solids it is not genuine, fat having been abstracted or water added—unless the contrary is proved. Reports on samples taken all over the country under the above-mentioned Act show that the average fat-content of all samples, including those obviously adulterated, exceeds 3·5 per cent., and is usually about 3·6 per cent. The standard of 3 per cent. is therefore a low one, and for this reason the Regulations of 1923 prescribed that the equivalent of fat in condensed or dried milk must be calculated on a 3·6 per cent. basis. For the moment, therefore, there is a legal standard of 3·6 per cent. of fat for condensed and dried milk, and a presumptive standard of 3 per cent. for ordinary milk. The Scottish Inter-Departmental Committee has recently expressed its dissatisfaction with this presumptive standard, and has recommended the substitution of a legal standard of 3 per cent. fat and 8·5 per cent. of non-fatty solids, evidently in hope of raising this standard later. The presumptive standard has certainly not worked well. Many conflicting decisions have been given. It has been held on the one hand that any fluid which comes from a cow's udder is milk, and on the other that a farmer may so treat his cows, by poor feeding and unequal inter-milking intervals, that the fluid coming from the udder may be regarded as not being milk. In some parts of the country, especially where the inter-milking intervals are very unequal, it has always been possible to procure expert evidence that the morning milk of a single cow frequently, and the morning milk of a herd occasionally, contains less than 3 per cent. of fat. Prosecutions are not undertaken when the fat is only 5 or 10 per cent. below the standard, and frequently fail when the deficiency is much greater. The presumptive standard of 3 per cent. is virtually only one of 2·7 per cent. The quality of milk as now supplied depends chiefly upon the honesty of the vendor and the complacency or otherwise of the buyer; during the period since 1875 we have got back to the principle of *caveat emptor*.

Among agriculturists it is recognised that, provided a cow enjoys a good ration, the fat-content of its milk is little affected by changes in its dietary. The late Mr. JOHN SPEIR, a member of the second Royal

Commission on Tuberculosis, produced much evidence in support of this view. Morning milk contains appreciably less fat than afternoon milk, and doubt may arise as to whether this difference is accounted for entirely by the difference in the inter-milking intervals. The publication by Mr. WILFRID BUCKLEY in pamphlet form of the result of experiments carried out at his Basingstoke farm, comes opportunely. The pamphlet is entitled "Some Observations on the Butter-Fat in Cows' Milk," and describes two investigations carried out in 1915 and 1922 respectively.

The first investigation dealt with the morning and evening milk of 65 shorthorn cows for 39 days (from April 18th to May 26th, 1915). From April 18th to May 5th the cows were stall-fed on a ration controlled by Mr. JAMES MACKINTOSH, a well-known authority on the feeding of dairy cattle. After May 5th the cows were turned out to grass, and had no other food. The analyses were made on behalf of the medical officer of health of Hampshire by Mr. SLIM, who resided at the Basingstoke farm during the investigation. At first all the cows were milked after intervals of 15 and 9 hours respectively, but later the intervals of two sections were changed to 13 and 11 hours and 17 and 7 hours respectively, while the third section kept to the intervals of 15 and 9. On nine mornings out of the 39 the mixed milk of the 65 cows fell below 3 per cent. of fat, the lowest record being 2·7 per cent. On the other hand, on only nine evenings did the mixed milk of the 65 fall below 3·9. On May 4th the morning mixed milk of the herd gave 3·17 per cent. of fat, and the evening milk 4·14 per cent. During this day 17 out of 63 cows gave milk containing below 3 per cent. at the morning milking, while 2 out of the 63 gave milk containing under 3 per cent. of fat at the evening milking. The morning and evening milk of a single cow (No. 195) for the whole period is given as an extreme example of variability. The morning milk of this cow varied in fat from 1·7 per cent. to 5·9 per cent., while her evening milk varied from 2·5 per cent. to 7 per cent. On the evening of May 1st this cow gave 9 pints of milk containing 6·3 per cent. of fat, on the following evening 9 pints containing 3·2 per cent. of fat, and on the morning between 11 pints containing 1·8 per cent. of fat. This cow appeared to be in excellent health throughout. The figures given show that, as a rule, the percentage of butter fat increases with the progress of lactation. The change from stall-feeding to grass was accompanied by a reduction in the percentage of fat for the whole herd from 3·71 to 3·61.

The second investigation was conducted by Mr. J. R. FRASER, of the Government Laboratory, on behalf of a committee of the Medical Research Council, several of whose members were present throughout.

The second investigation lasted five days, from April 24th to April 28th, 1922, and confirmed the results of the first with respect to the daily variation in the fat percentage of the milk. One cow in this investigation gave about 6 gallons of milk daily, and an average of 2 per cent. of fat in the morning and 4 per cent. in the evening. Her subsequent record was kept, and although for the next few months she seldom gave 3 per cent. of fat in the morning, her annual yields of fat and non-fatty solids were 2·14 and 2·25 times those of the average milch cow in Great Britain.

The experiments with regard to altering the inter-milking intervals gave somewhat discrepant results. We venture to suggest, however, that for several months the cows experimented on had been milked at intervals of 15 and 9 hours, and that udders probably acquire habits, and can hardly be expected to make a machine-like response to a change of this kind.

We have discussed Mr. BUCKLEY's investigations at some length, because we hope they may lead up to others. We can hardly have one legal standard for morning and another for evening milk, even should equal inter-milking intervals prove impossible to achieve. Nor do we want a legal standard of 3 per cent. of fat, when we know that the average of the milk supplied to the public at present contains nearer 3·6 per cent. For condensed and dried milk we have already adopted the standard of 3·6 per cent. Both these concentrated milks are produced in this country, and we are up against the anomaly that the morning milk of dairy-herds cannot be used alone for the making of condensed or desiccated milk without infringing the law. The problem is a difficult one, and there is no case for hurried legislation.

ANTI-LEPROSY MEASURES.

THE object of the British Empire Leprosy Relief Association is to stamp out leprosy in the British Empire, and the Viceroy of India, in his message to the Mansion House meeting last week, was no doubt perfectly justified in saying that the time is auspicious for an earnest campaign to combat this terrible scourge. Time was when nothing but the certainty of a specific cure would have obtained from a benevolent public the means to carry out effectively such a campaign. Fortunately the Association is not lending itself to propaganda which cannot be fully substantiated, and a larger public is likely to enter with zest into the game of attacking a disease in which resource and ingenuity are essential and in which finesse is not out of place. Leprosy when acquired is not the inevitable and incurable horror which it is held to be; it is a self-healing disease, in typical cases of which immunity is gradually produced. We are happy to set out and emphasise this statement of Dr. ERNEST MUIR, research worker in leprosy under the Indian Research Fund Association and successor to Sir LEONARD ROGERS in his work at the Calcutta School of Tropical Medicine and Hygiene. From new knowledge of the natural history of the disease will follow logically the methods by which its recovery can be helped or accelerated. During the first two stages the chief object of treatment is to restore the lowered tissue resistance and prevent the disease from passing on into the third stage. When, in spite of these attempts, the third stage has been reached, the aim of treatment is then to bring about moderate reactions so as to hasten the resolution of the lesions before deformity and disablement occur. Finally, in cases which have passed through the third stage, cure may be hoped for in so far as active disease is concerned. These are the immunological principles upon which the campaign will be based, and as Prof. ROGERS was at pains to set out, the Association will make a threefold effort (1) to bring known improvements in treatment within the reach of existing lepers, (2) to support existing efforts at segregation so far as the schemes are sound, and (3) to inaugurate research into the spread of the disease and further possible improvement in the methods of local treatment. For it is surely unjustifiable, as indeed the International Leprosy Congress agreed last year, to segregate lepers for the benefit of others without supplying the best possible treatment for the victims. This is a reasonable campaign to which the best powers and abilities of many varieties of workers can be unhesitatingly given. It is worthy of support by a thinking public.

Annotations.

"Ne quid nimis."

EASTER MEDICAL TOURS IN FRANCE.

THE eighteenth Voyage d'Études Médicales will take place at the Easter season of this year. These tours are organised by a central bureau in Paris, and are under the scientific direction of Dr. Paul Carnot, professor of therapeutics in the University of Paris, assisted by his professeur agrégé, Dr. Rathéry. For 14 years before the war the V.E.M., as the organisation is known to French medical men, conducted tours designed to make better known to French and foreign doctors the various spas of France. After an interruption of six years the tours were resumed in 1921, and have grown increasingly popular in this country. Each year a different district is chosen for study; in 1922 a visit was paid to the sulphur springs of the Western Pyrenees, of which a full and illustrated account appeared in THE LANCET.[1] In the autumn of 1923 a delightful journey was taken through Savoy, the Dauphiné, and the Jura, where the claims of several well-known spas were studied. This year the projected tour embraces the spas of the Mediterranean, and in consequence the usual date has been altered, for late summer does not offer the ideal climatic conditions from the therapeutic point of view. Easter has therefore been selected as the most advantageous season, but as the holiday time at the disposal of doctors at this period of the year is generally limited, the eighteenth V.E.M. will consist of three independent tours. The principal tour will include the resorts in Provence and on the Côte d'Azur, and will extend from April 17th to 23rd. The starting-point is Aix-en-Provence, and members will disband at Nice. The number of participants is limited to 180 and the cost of the tour is 450 francs.

A preliminary tour of the resorts of Cerdagne and the Pyrénées orientales is under consideration. Members are due to arrive at Carcassonne individually on April 13th, and after visiting the town will leave on the following day by motor cars for the Valley of the Aude, Usson-les-Bains, Mont-Louis, Font Romeu, les Escaldes, Thués-les-Bains, Vernet-les-Bains, Le Boulou, Amélie-les-Bains, Banyuls, and Montpellier; joining the principal tour at Aix-en-Provence on the morning of the 17th. The maximum number of participants is 60, and the approximate cost 350 francs. Lastly, a tour is contemplated in Corsica for the period from April 23rd to 27th, crossing from Nice to Bastia, and proceeding to Orezza, Corté, Vizzavona, Piana, and Ajaccio. The return journey to Nice, or, if possible, Marseilles, will probably be made on the evening of the 27th. This tour is also confined to the maximum number of 60 members and will cost 400 francs. As in former years, a reduction of 50 per cent. will be granted by the French railways to doctors and medical students (from place of residence or from the frontier station to the place of concentration and vice versa). It must be noted, however, that the committee of the principal railways have decided to cease the extension of this facility to the wives or daughters of doctors.

Any members of the medical profession desirous of participating in the eighteenth V.E.M. are asked to communicate as soon as possible with Madame M. C. Juppé-Blaise, representative of the French Spas, at the Office Français du Tourisme, 56, Haymarket, S.W. 1. They are requested to state whether, in addition to the principal tour of the Côte d'Azur, they wish to take part also in the tour of either Cerdagne or Corsica, or both. Participants who wish to be accompanied by their wives or daughters, should circumstances permit of suitable arrangements being made, are asked to state whether they would be prepared to go alone in case such arrangements could not be carried out.

MUSCULAR ABNORMALITIES.

IN a paper on this subject in our present issue Prof. Gordon Harrower mentions four or five interesting abnormalities which have come under his notice in the dissecting room at Singapore. Two of these muscular anomalies, at least, have the added interest that they might conceivably possess a clinical bearing. The rectus sternalis is a well-known variant. Prof. Harrower figures a very well-developed bilateral specimen. It must be recognised, however, that the muscle is usually unilateral, but when it is double it may have different shapes and directions of its fibres, and during life, if contracting, may produce very curious effects, quite inexplicable to those that are ignorant of the structure. The careful studies of nerve supply mentioned by Prof. Harrower are of great interest to the morphologist in view of the present tendency in viewing the muscle. His division of the specimens into two classes appears to be acceptable, but this does not exclude a mixed class more or less analogous with the fibres of the "achselbogen." The abnormal additional origin of the gastrocnemius is one which might cause confusion in operative measures undertaken in this region. Such slips, arising like this one or from some adjacent part, are not excessively rare, and on that account perhaps deserve notice. Without definitely adopting the views of Testut and others, that these structures are always atavistic, it might perhaps be conceded that such extra-popliteal origins of the gastrocnemius are remnants of a more extensive or conjoined area of origin, pierced by the enlarging anastomosis which forms the popliteal artery.

CLINICAL RONTGENOLOGY.

THE phrase is ungainly, but it describes accurately enough the subject-matter of a much needed work from the Mount Sinai Hospital, New York, on all aspects of the radiology of the chest.[1] Drs. Wessler and Jackes make no extravagant claims and have not hesitated to point out the limitations of X rays in respect of diagnosis. The reader is warned against making a hasty diagnosis from the plate, for the blood-vessels and bronchi throw shadows which vary in different normal lungs and which should not be confused with shadows resulting from disease. Especially difficult to interpret are the shadows of the lung roots, and we agree with the authors that it is "particularly unfortunate that the shadows at the roots of the lungs have so often been made the basis for the diagnosis of pulmonary tuberculosis by roentgenologists." The authors are of the opinion that the earliest lesions in pulmonary tuberculosis appear in the infraclavicular region near the apex of the lung, and are nearly always unilateral. Hilum tuberculosis they believe to be very rare, and the so-called peribronchial phthisis to be the result of shadows of dilated blood-vessels and lymphatics. For the early diagnosis of pulmonary tuberculosis fluoroscopy is important as it will show deficiency of aeration at an apex and also abnormalities in the movement of the diaphragm, but shadows due to areas of disease are more easily seen on the plate. The authors state that an area of infiltration situated near the surface of the lung must be at least 4 mm. in diameter to cast a shadow, and the deeper the disease is situated the less clearly will it be seen. There are numerous plates showing pulmonary tuberculosis in all its stages, and of special interest are the three plates illustrating a case of acute pulmonary tuberculosis in its early, middle, and late stage. Undoubtedly X rays are of great value in the early diagnosis of pulmonary tuberculosis, but the history and condition of the patient must be taken into account, for similar shadows may be cast by non-tuberculous conditions. The question as to whether a lesion is active or arrested should, we are told, be

[1] Clinical Roentgenology of Diseases of the Chest. By H. Wessler, M.D., Adjunct Physician and Associate Roentgenologist, Mt. Sinai Hospital, New York; and Leopold Jackes, M.D., Roentgenologist to the hospital. Troy, N.Y.: The Southworth Company. 1923. With 430 plates. Pp. 560.

wisely left to the clinician. In discussing advanced tuberculosis it is shown how sometimes blood-vessels or pleural adhesions may cast shadows closely resembling cavities, and these shadows are accentuated by pneumothorax. It is unfortunate that X ray findings are not more frequently compared with post-mortem results, or by this means alone could the real meaning of the various shadows be put beyond doubt. Dr. Homer L. Sampson in a recent article [2] describes an experiment in which ten guinea-pigs were inoculated with tubercle bacilli by inhalation and killed at three-day intervals after the tenth day. X rays showed small shadows after the sixteenth day which proved to be tubercles. He does not think the shadows of tuberculosis absolutely typical of the disease, but they usually form a characteristic picture. The article is well illustrated by a series of 16 radiograms. Such works as these are welcome because, although the X rays are of importance in chest work, the clinician is as apt to underrate their value as the radiologist is to exaggerate it.

FOOT-AND-MOUTH VIRUS AND MONKEYS.

ATTENTION was called last week to the probable susceptibility of rodents to the virus of foot-and-mouth disease. A short paper in the most recent number (December, 1923) of the *Annales de l'Institut Pasteur* relates certain preliminary attempts by MM. Menzinescu, Baroni, and Calinescu, carried out between December, 1913, and June, 1914, to transmit the disease to other animals. All experiments upon cultivation, using most of the media and special techniques which have from time to time been devised for the culture of delicately growing organisms, then gave entirely negative results. In a further series of experiments attempts were made to grow the virus in collodion sacs within the peritoneal cavity of various animals, a procedure which has proved successful in the case of certain other filtrable viruses. In no case was success achieved, but, on the contrary, the virus rapidly became ineffective under these conditions and was presumed to have died. In other experiments Chamberland bougies were filled with virus-containing fluid and introduced into the peritoneal cavity of susceptible animals. In these cases the animals speedily contracted the disease, presumably by penetration of the virus through the porous walls of the filter. The fluid contained within the filter candle was found to retain its infectivity after a sojourn of eight days in the peritoneal cavity. Attempts to transmit the disease to rabbits, by various routes successful in other diseases, altogether failed, but in seven cases in which the virus was injected into monkeys there appeared, after an incubation period of three to five days, a vesicular eruption affecting the skin and mucous membranes, accompanied by a brief access of raised temperature. It would seem, therefore, that such animals are definitely susceptible, and if this is found to be the case at the hands of other workers it should prove a valuable step forwards in the investigation of a baffling malady.

TUBERCULOSIS IN INFANCY.

Dr. Norman B. Capon,[3] hon. pædiatric physician to the Liverpool Maternity Hospital, who records a remarkable case of tuberculosis in infancy, remarks that in most examples of tuberculosis at this age the disease has been acquired after birth either by inhalation or ingestion of tubercle bacilli. The present case, in which death occurred on the forty-first day after delivery, illustrates the difficulty in deciding by what route infection had taken place. The mother, aged 29, was admitted to hospital to undergo Cæsarean section for pelvic deformity. Her previous five labours had been instrumental and had resulted in stillbirths. Cæsarean section was performed and a full-term and apparently normal infant, weighing 8 lb. 12 oz., and measuring 20 in. in length, was delivered. The placenta, umbilical cord, and membranes were macroscopically normal and were not saved for microscopical examination. The mother's temperature rose to 101·6° F. on the day after the child's birth, and ran a remittent course until death, which occurred 44 days after delivery. The autopsy showed that death was due to acute miliary tuberculosis, tubercle bacilli being found in the lungs, brain, spleen, kidneys, and uterus. The baby was breast-fed for a few days after birth, but as the mother's temperature did not fall, artificial feeding was substituted. The child, however, remained in contact with her mother for the first 25 days of life. When first seen by Dr. Capon 33 days after birth the child was marasmic and of a bluish colour. There were no physical signs of lung disease, but the abdomen was distended and the liver and spleen were enlarged. Wasting became more pronounced, pyrexia developed and continued until death. At the autopsy the principal morbid changes were found in the lungs, spleen, and liver, which showed scattered throughout their substance tuberculous masses of various sizes, most of which had undergone necrosis and caseation, except in the lungs, where no caseation was found. The mesenteric glands showed almost complete necrosis and caseation at their centres. Small areas of caseation were also found in the thymus. Dr. Capon discusses the possible channels of infection by which an infant may become tuberculous—viz., germinal infection, intra-uterine infection, intra-partum infection, and neo-natal infection—and while maintaining that it is impossible to state definitely the route by which infection occurred, especially in view of the fact that the placenta was not examined histologically, points out that the advanced stage of the lesions found in the child's viscera supports the possibility of intra-uterine infection. There is no satisfactory treatment for tuberculosis in the newborn, but prophylaxis demands that a baby born to a mother with active pulmonary tuberculosis should be removed from her as soon as possible and isolated from other babies.

MALTA FEVER AND EPIZOÖTIC ABORTION.

THE organisms responsible for Malta fever in man and epizoötic abortion in cattle are hardly distinguishable from one another by laboratory tests, and there is evidence that vaccination with one may protect against the other. Epidemiologically the distinction is quite clear: the one causes Malta fever in goats and men, while the other is still more widely prevalent in cattle and to some extent in pigs. But there is no evidence that Malta fever ever gives rise to epizoötic abortion or vice versa; the diseases breed true, though the organisms are nearly identical by other criteria. It has been suggested that the old agricultural custom of running a goat with cattle in the fields as a preventive against abortion may represent a realisation of a close relationship and the possibility of prophylactic inoculation; some notes on the practice in different parts of England and Scotland have appeared in our columns.[1] Careful work[2] by Miss Alice Evans on a large number of strains from various sources has shown that the organisms can, by agglutination and absorption tests, be divided into two main groups: *Brucella melitensis melitensis* from goats and man, and *B. melitensis abortus* from cattle and pigs; the differences are quantitative rather than qualitative, and are not great. In the *Johns Hopkins Hospital Bulletin* (1924, xxxv., 6) Dr. C. S. Keefer gives a very full account of one of the few cases of Malta fever which have been identified in America. The clinical course was typical, and the organism was repeatedly isolated by blood culture. The patient had never been abroad, nor for a long time outside the city of Baltimore, and had had no contact with goats. What is of particular interest is that Miss Evans found the strain isolated from

[1] THE LANCET, 1922, ii., 546, 743.
[2] Ibid., 1922, ii., 979.

him to belong to the *abortus* subspecies. Epizoötic abortion is common enough in the Eastern States, and almost everybody is apt to come into contact with it through milk. We have here, then, apparently for the first time, an example of variation in the pathogenic relations of this organism. Cases cannot be common. But they may be less rare than is supposed, for the symptoms of human infection are sometimes equivocal, especially if the possibility of Malta fever is not in mind. A certain number of the obscure pyrexias may turn out on fuller and specific examination to be *abortus* infections, the possibility of which is almost universally present.

The other familiar example of the pathogenic distinction of almost identical organisms is found in plague and pseudo-tubercle. The organisms are indistinguishable and to a certain extent cross-vaccination succeeds. But plague is a disease of rats, and pseudo-tubercle a disease of guinea-pigs, and there is no direct evidence that one may become the other. It is, however, obviously possible that some of the obscure outbreaks of plague, such as that in Suffolk a few years ago, may have been due to a variation of the pseudo-tubercle bacillus in that direction—a possibility not much more difficult to believe than the well-known facts of variation in cultural characters.

READING IN BED.

READING in bed, as Becky Sharp might have said, "may be wicked, but it's natural," and many people confess to being incurably addicted to the practice. Books to be read in bed naturally divide themselves into two classes, those which do not keep the reader awake and those which provoke an exposition of sleep. Mr. Osborn's lists of books,[1] including those from which excerpts are given, all fall into the former class, except, somewhat oddly to our thinking, Malory. Of the latter class we can quote two, of which we feel certain Mr. Osborn will be glad to know—namely, the Rev. Robert Montgomery's poem "Woman: The Angel of Life," and a book of surpassing excellence in its way—namely, "Mogg's 10,000 Cab Fares." The former work, as Thackeray discovered long ago, has the great advantage that it makes just as good sense read from the end to the beginning, as from the beginning to the end, while the latter not only is the sole work of literature which appealed to Mr. Soapy Sponge, but in addition can transport the reader to realms of dreams in which, as is the way of dreams, he may traverse London in several directions at once. Let the sleepless reader once begin "Acton five, from the end of Oxford Street and the Edgware Road—see Ealing; Edmonton seven, from Shoreditch Church—'Green Man and Still,' Oxford Street, Shepherd's Bush and Starch Green, Bank and Whitechapel . . ." and sleep will come. Mr. Osborn's introductory essay is delightful reading, especially his précis of the Russian novel, but all the same we do not think he can have read Chekhov. The authors from whose works he gives selections are mostly not later than the eighteenth century and include such masters as Thomas à Kempis, Robert Burton, Apuleius, Froissart, and Sir Thomas Browne, while of the two moderns Mrs. Gaskell is represented by the till recently unpublished record of the childhood of her daughter and a very charming record it is. The latter half of the book is made up of a fragment from Anatole France's "Clio," a paper on "Dreams" by Lady Grey of Fallodon, an admirable antidote, as Mr. Osborn says, to the Freudian theory on the subject, and sundry papers by Mr. Osborn himself, all of which are restful and pleasant reading. One of these deals with Christmas carols, again delightful to read in bed or anywhere else, but which cannot be written now, and another with epigrams of which Mr. Osborn quotes a few, both ancient and modern. We will add one, known to few, but all the same singularly happy. All Eton men whose memory of masters goes back to the "seventies" of the last century will remember Russell Day, a great mind in a small body. One of his relatives married a Miss Week, and Day handed in the following at the wedding:—

> "A Day the More a Week the Less,
> Yet Time must not complain,
> There'll soon be little days enough
> To make a week again."

Another paper discourses pleasantly on diaries, in which Mr. Osborn naturally gives the palm to Pepys. But we recently came across another diary or excerpts from it, rescued from oblivion by Mr. R. L. Hine in his book (a bedside book of the best class) called "The Cream of Curiosity." The diary in question was kept by Justinian Paget, born in 1610, in which we find such entries as the following: "I lay in bed musing till 9 o'clock which caused a dulness in my head with losse of so much time. *Resolve* that wakening at 5 o'clock I will knock with my bedstaff to waken Elias, who shall presently rise and make a fire whilst I rubb my body and then I will presently skip out of bed." A marginal note adds, "I must have ye tinder box with me."

Sleeplessness is a sore trial to many, and even though we are indebted to the condition for some masterpieces of literature such as Statius's poem to Sleep, it is a condition to be combated. Mr. Osborn's book will certainly be a boon to the sleepless.

ULTRA-VIOLET IRRADIATION OF THE MOUTH.

AT a meeting of the Odontological Section of the Royal Society of Medicine on Jan. 28th Mr. P. S. Campkin showed an apparatus for applying ultra-violet rays in the mouth, invented by Mr. R. B. C. Sheridan, Barrister-at-Law. The device[1] consists of a mirror and two quartz lenses of different powers, all of 41 mm. diameter, and mounted on short handles connected by a pivoted hinge. The mirror is adjusted so that the patient can see the interior of his own mouth when the lenses, which are permeable to ultra-violet rays, are arranged to focus the sun's rays on an area of about the size of a threepenny-piece. For irradiating areas in the front of the mouth the two lenses are superimposed; if a longer focal length is desired—e.g., for the back of the mouth—one lens may be pushed aside. Should sunlight not be available the light from a mercury-vapour or an arc lamp can be substituted. The device is intended to be used by the patient at home. Mr. Campkin stated that he had found ultra-violet radiation thus applied useful in promoting the healing of raw surfaces following extraction of teeth or the removal of cysts, as well as in marginal gingivitis and after excision of hypertrophied gums. Radiation is applied for a period of five to ten minutes two or three times a day. Mr. Campkin went on to suggest that the device might be useful as a prophylactic measure against pyorrhœa; adding that the exposure was so short as to eliminate any danger of burning. The device had received favourable comment from Dr. Murray Levick, who thought it should prove useful for the treatment of oral lesions. On the analogy of the use of ultra-violet rays for other conditions, it seems reasonable to assume that the healing of the oral tissues may be hastened by the use of these rays in the mouth. Personal equation comes much into play in estimating the value of such treatment, especially when it is ancillary to dental treatment of other kinds, and until a large number of cases have been treated by different observers, the actual therapeutic value must remain uncertain. Mr. Campkin alluded to the risk of burning, and we should like to have assurance from physicists and those versed in heliotherapy that burning is optically impossible. There is a wide difference between the use of an instrument under careful supervision in hospital and as a form of home treatment.

[1] The apparatus has been protected under the name "Oralight" lens, and can be obtained from Messrs. Pankhurst and Barritt, 56, New Cavendish-st., London, W., at a cost of 30*s.*

MANGANESE IN HARROGATE WATERS.

THE pharmacology of manganese as a constituent of many medicinal waters has not been the subject of extensive research. Though the amounts present are usually small, they are amenable to accurate measurement, and the chemical importance of the element is sufficient to warrant some discussion. Potassium permanganate is the only salt compound of manganese in the official pharmacopœia, and in this case it is not the manganese but the high oxygen potential of the acidic ion which is required in the prescription. Recent developments of colloid therapy have focused attention on manganese in the colloidal condition. Years ago it was more freely prescribed. As a cathartic the salts were given in combination with other purgatives such as senna, and in doses of 5 to 10 gr. it was prescribed as a tonic, sometimes in place of iron. It was also supposed to have an action on hepatic function, increasing the secretion of bile. Dr. David Brown has shown the action of sulphur water to be one of increased oxidation. "The evidence brought forward," he wrote,[1] "as to the stimulation of a ferment like the xanthin oxidase of the liver suggests that its principal effect may be brought about by a peroxidase." Mr. A. Woodmansey, M.Sc., analyst at the Harrogate Royal Baths, calls our attention to the fact that the Old Sulphur Water of the spa contains small amounts of manganese which may be responsible for the observed effects. The amount of manganese in the other waters is as follows:—

	Manganese (parts per 100,000).
Old Sulphur Water	0·03
Strong Montpellier	0·04
Mild Sulphur	0·025
Chloride of Iron	0·04
Crescent Saline	0·12
Tewit (Tuewhit)	0·044

The outstanding property of manganese, its activity as a catalyst in the promotion of oxidation, explains its effect on plant and mould growth. The oxidising enzyme of the lac tree has been found to contain much of the element, and it is highly probable that manganese may function as a peroxidase under certain conditions. The manganese content of the Harrogate waters is sufficient in quantity to merit an investigation of its catalytic possibilities. Work is now being done in order to find whether the manganese of imbibed waters is immediately excreted or retained by the body.

ON ŒDEMA.

IT was for a long time customary to consider œdema as a chapter in the pathology of lymph formation, and it was in this country sadly mixed up with the Starling-Heidenhain controversy about lymph flow; it was overlooked that the mystery of œdema is not why more fluid leaves the vessels for the tissue spaces, but why it stops there instead of draining away into the veins and lymphatics. During the last fifteen years or so—starting perhaps with the splendid chapter in Lazarus-Barlow's "General Pathology"—one has come to look on œdema as due to interference with the mechanism which regulates the distribution of water in the body between the blood, the lymph, and the tissue fluid. The main factors as far as we know which determine this distribution are the permeability of the capillary wall (as in histamine wheals) and the concentration of dissolved substances (as in salt œdema). Prof. L. Loeb has put together[2] an admirable conspectus of the subject from this point of view, discussing systematically the considerable volume of germane investigations made in recent years, and dealing fairly with the pros and cons of the various ideas which have been put forward to explain the common, and still the most complicated, cases of œdema in cardiac and renal disease. In the former class, for example, the meaning of Bolton's classical work in making the traditional mechanical explanation quite impossible is fully appreciated; in the latter, the possibility is raised at some length that the immediate cause of the accumulation of fluid in the tissues is not the failure of the kidney to excrete but the production by the kidney of something, possibly the soluble products of autolysed cells, which alters the permeability of the capillary walls throughout the body—a suggestion made by Chisolm ten years ago. The book is a solid piece of work, not very lively reading for the style is rather dull, but it not only sets out the state of present knowledge on the subject, but suggests many new lines of inquiry.

THE LATE PROF. MARCUS HARTOG.

MANY members of the medical profession will have learnt with regret the recent death in Paris of Prof. Marcus Hartog, who for 41 years was associated as a teacher of biology with the medical schools of Manchester and Cork. He had retired from work for several years and had reached the age of 75. A versatile and learned writer, we were on many occasions the recipient from him of notes, generally in amusing vein, illustrative of quasi-medical points, his justification for appearing anonymously in a professional newspaper being that his long connexion with medical education had made of him "a perpetual student." The last such note, written in refutation of the public belief that the rocking cradle was bad for the infant is a good example of his shrewdness to detect the fallacies of popular theories:

"One great objection has been that rocking stirs up the pulpy brains. Now the brain and other liquids completely fill up the cavity of the skull, and, moreover, it is traversed by intersecting membranes. You can't agitate even water in a completely full vessel, and the brain is very much less fluid than water, or even gum-water; try the experiment and you will see the absolute futility of the theory. In the next place consider the zoological argument. The infant ape is carried about either clinging to the fur of its mother, or held in its arms, but despite the constant rocking it must get, its health doesn't suffer. The habits, and I may say the instincts, of women are all in favour of rocking. When a woman takes a child in her arms she at once begins swaying to and fro, if standing; when she walks, of course the child she carries is rocked. The Indian and Ceylonese mothers extemporise a hammock of a sheet suspended from a tree for the infant to sleep in, and from time to time give it a swing with the hand or foot. I think it very unfair that after the nursling has enjoyed some months of rocking with every movement of its mother, it should be suddenly deprived of its wonted passive exercise."

Prof. Hartog's equipment was remarkable. To an intimate acquaintance with zoology, botany, and even geology, he added the ability to read and correspond in five languages and was a keen and critical appreciator of music. Although his academic work was mainly in biology, he started his scientific career as assistant-director of the Ceylon Botanical Gardens.

AFTER-CARE OF TUBERCULOUS EX-SERVICE MEN.—The Minister of Pensions announces that arrangements have now been made to secure the coöperation of the local agencies of the Ministries of Labour and Pensions with the local health authorities in the after-care of ex-Service men suffering from tuberculosis. Six weeks (or as long as possible) before the tuberculous man's discharge from an institution, the notification of the pending discharge will be sent to the tuberculosis officer of the man's place of residence. Thereupon, special steps will be taken, on the one hand, so that, as far as possible, the patient shall not return to home conditions which are likely to prevent the satisfactory progress of the case or to cause a relapse; and at the same time, on the other hand, to do all that is possible to assist the man to obtain employment in a suitable occupation. So far as the man's home conditions are concerned, the tuberculosis officer and his staff, or the Tuberculosis Care Committee, if one has been established in the area, will, if these conditions are unsatisfactory, take such action as may be practicable to improve them. As regards the man's employment, if the tuberculosis officer considers that the man's occupation is unsuitable, he will furnish the Employment Exchange with a list of occupations which he considers not definitely unsuitable for the case. The Employment Exchanges will render all possible assistance in this matter, and special efforts will be made by the King's Roll Committee and by the Chief Area Officer and the members of the War Pensions Committee.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LVII.—THE TREATMENT OF ACUTE SEPTIC INFECTION: SEPTICÆMIA.

FOLLOWING infection of certain tissues by certain micro-organisms, the disease process is apt to spread rapidly, and sooner or later microbes extend beyond the site of primary infection and entering the blood-stream multiply therein, giving rise to septicæmia.

The tissues infection of which is specially prone to be followed by symptoms of general infection are bone (osteomyelitis); the uterus—e.g., puerperal sepsis; the skin and subcutaneous tissues—e.g., erysipelas, cellulitis, an infected wound; the middle ear and upper respiratory tract. In osteomyelitis the infecting agent is usually *Staphylococcus pyogenes;* of the remainder *Streptococcus pyogenes* accounts for the large majority.

The diagnosis of a generalised infection is often difficult on clinical grounds alone; the general condition of the patient is apt to be deceptive, particularly in the more acute cases. The diagnosis will be based on (1) a sudden rise of temperature and in pulse-frequency, both sustained, and perhaps (2) the occurrence of chills or rigors, and (3) the development of secondary foci—e.g., pulmonary infarct, pleurisy, or arthritis. The certain sign is the presence of micro-organisms in the blood-stream, but many cases are undoubtedly septicæmic in which blood culture is negative during life; further, it may be three or four days before a report can be received—time that cannot be spared in instituting treatment. The great value of blood culture is that when positive it yields the infecting organism in pure culture. Treatment in such cases is often of little avail, but in order that the patient may have the best possible chance it is essential that it should be started early, and for this reason it is far safer to treat any doubtful case as though it were septicæmia instead of waiting for the diagnosis on the result of blood culture.

Treatment may be considered under four headings:

1. *Local.*

Efficient surgical measures for drainage and elimination, as far as is possible, of the primary focus. The importance of this first step in the treatment of infective processes cannot be too strongly emphasised; the frequency with which it is overlooked is the justification for the italic type in which it is expressed.

The same remarks apply to secondary foci which may arise in the course of the disease, but in streptococcal cases an effusion into a pleural or joint cavity may usually be aspirated, unless the liquid be thick pus, on one or more occasions before drainage is advisable. Constant watch must be kept over the pressure points—gluteal, heels, elbows, &c.—for the development of subcutaneous abscesses which require immediate incision.

2. *General.*

(*a*) *Food and Hygiene.*—Good nursing is essential. An efficient nurse will get her adult patient to take at least 4 pints of assorted fluids in the 24 hours, and the patient may be allowed anything fancied in the way of solids, regardless of temperature; it is a mistake to limit the dietary entirely to slops. Meat, fish, chicken, vegetables, and plenty of fruit and eggs should be pressed. In those rare instances in which it is impossible to get solids down, four or five eggs beaten, during the 24 hours with Benger's, ovaltine, plasmon, jellies, and meat essence must be reluctantly substituted, a return to solids being made at the earliest opportunity. The mouth must be cleaned before and after every feed, and a little simple ointment applied to the lips will help to keep them moist. The bowels should be kept on the free side. Abundance of fresh air is essential, bed on a balcony continuously is the ideal, though but rarely attainable. Great care is necessary to avoid bed-sores; the back should be washed, dried, rubbed with hazeline solution or spirit, and powdered at least every six hours. Urinary output should be measured. When the temperature exceeds 103° F. the patient should be cradled; if it rises to 104° sponging with hot water (110°) will bring it down without causing the discomfort often associated with tepid sponging.

(*b*) *Rest.*—A detail often necessary to enforce. The patient, usually mentally alert and free from headache, must be kept quiet, visitors cut down to the minimum, and all movement in bed restricted as far as possible. Sleep is of the utmost importance and must be secured at all costs, and the patient should never be awakened for feeding or treatment. Insomnia, due more often to toxæmia than pain, may yield to ammonium bromide and chloral, or medinal, if simple nursing methods fail; the constipating effects of opiates can be overcome by salines and enemata.

(*c*) *Drugs.*—The administration of medicine, stimulant, and hypodermic is to be so arranged that they do not clash. The indication for drugs as a routine in the early stage is—

(i) to aid elimination,
(ii) to prevent heart failure,
(iii) to prevent abdominal distension and diarrhœa.

To this end sodium bicarbonate may be added to barley-water, and sodium citrate to fresh lemonade; half a drachm of the tincture of digitalis should be given in the 24 hours, and will save time should the necessity for sudden digitalisation arise as an aid to pituitrin and strychnine at a later stage. A small dose of hyd. c. cret. and salol or other so-called intestinal disinfectant may be given with advantage twice or thrice daily. Brandy should be started early, but never added to a feed—say 2 oz. in the 24 hours, half of which may be given at 9 P.M. in the hope of inducing sleep.

3. *Special Treatment.*

When the above items have been thoroughly attended to, but not before, the question of specific treatment must be considered. In the case of staphylococcal infection but little is to be hoped for on specific lines, but fortunately in streptococcal infections specific therapy is often of great value.

(*a*) *Sensitised Vaccine.*—Mervyn Gordon has shown by the absorption of agglutinin test that hæmolytic streptococci can be differentiated into three distinct types. The vast majority of pyogenic streptococci causing localised or general streptococcal infections, other than scarlet fever, belong to one and the same serological type. Hence a stock sensitised streptococcus pyogenes vaccine may be used with confidence in the majority of cases, and should certainly be employed in all until an autogenous one can be prepared. For an adult the dose of sensitised streptococcus pyogenes vaccine may well be 100, 250, and 500 million given subcutaneously on three successive days; after an interval of a few days, 250, 500, and 1000 million may be given in like fashion, or perhaps 100 million daily or every other day. Alternatively to the subcutaneous route 100 to 500 million sensitised vaccine may be injected intravenously combined with antistreptococcus pyogenes serum intramuscularly. Such tactics may induce a rigor; an "extraneous rigor" in such conditions is always of good prognostic import.

(*b*) *Antiserum.*—Provided the patient has not had serum administered before and is not subject to asthma, hay fever, or urticaria, antistreptococcus pyogenes serum should be given at once; polyvalent serum under such conditions is of comparatively little value. At least 50 c.cm. are injected intramuscularly into the thigh or flank and the dose repeated in 24 hours; in urgent cases serum may be diluted with an equal volume of sterile Ringer's solution or normal saline and given intravenously. Should the patient have

ad serum previously or be an asthmatic, an intra-ermal test must first be done with the serum as a recautionary measure, and if hypersensitive, desensi-isation with small doses must be carried out before he full dose is given.

(*c*) *Peptone.*—Nolf, of Liége, first recommended the ntravenous injection of Witte peptone in septicæmia nd severe septic infection in 1917, and it is undoubtedly useful accessory to other forms of treatment. Judged olely by its immediate effect on the temperature hart, peptone in streptococcal infections would most imes be regarded as of small account, but if the eneral condition of the patient is considered one arely fails to be impressed by its worth, except in the ery acute fulminating cases. It is the general con-ition and not the chart which must be taken as the uide to the size of the dose of peptone and the requency of its administration; if it is of benefit a hange will be manifest within 12 hours of the first njection though three or four may be required before he temperature shows signs of abating. Witte eptone is given as a 10 per cent. solution in distilled ater and the initial dose for an adult is from to 8 c.cm. It should not be given to asthmatics. he requisite dose of peptone solution is drawn into record syringe fitted with a needle not larger than o. 26, to avoid the risk attendant upon a too rapid ntroduction of peptone into the blood-stream. The ntravenous injection of 8 c.cm. should occupy at least wo minutes, and during the operation the nurse keeps onstant observation on the pulse-frequency, calling ut the number of beats in each quarter of a minute; this exceeds 35, or should there be any complaint f pain or discomfort by the patient, the injection is emporarily suspended, to be resumed, even more lowly than before, when such signs have moderated. n the majority of cases of acute infection in which good result appeared to follow the intravenous njection of peptone, a rigor occurred within an hour r so of the first administration; in others the desired eaction was delayed until after the second or third ose. A rigor under such conditions is to be regarded s a favourable sign, and failure to react is of grave rognostic import.

The condition of the patient during the reaction ay be alarming to the uninitiated; for a short time he may be cyanosed, restless, dyspnœic, and the ulse impalpable at the wrist; but these signs are f short duration and relieved by brandy, hot bottles, nd a hypodermic injection of adrenalin or atropine ulphate.

The injection of peptone may be repeated in 48 ours, the dose being increased by 1 or 2 c.cm. ntravenous injection, whether of peptone, serum, or accine, should not be made directly after food has een taken.

Every case of streptococcal infection has to be udged on its merits, but for a case of, say, puerperal epsis coming early under treatment the initial easures under this heading might be—

(*a*) 100 million sensitised streptococcus pyogenes vaccine subcutaneously;

(*b*) 50 c.cm. antistreptococcus pyogenes serum intramuscularly;

(*c*) 6 c.cm. 10 per cent. Witte peptone intravenously.

4. *Supplementary.*

(*a*) *Infusion.*—In those rare instances where omiting and diarrhœa render the absorption of an dequate quantity of fluid impossible, and in which the oxæmia is overwhelming, infusion of Ringer's, or ormal saline solution, to which 5 per cent. of glucose s added, may be of benefit.

(*b*) *Transfusion of Blood* is of undoubted value, specially in subacute cases. It should be employed articularly in those associated with severe anæmia, n which it enables the patient to obtain greater enefit from other lines of treatment.

A. E. GOW, M.D., F.R.C.P. Lond.,
Assistant Physician, St. Bartholomew's Hospital, London.

Special Articles.

SMALL-POX AND VACCINATION.

BY C. KILLICK MILLARD, M.D., D.SC. EDIN.,
MEDICAL OFFICER OF HEALTH, LEICESTER.

Dr. J. C. McVail's Address to Members of Parliament.

ON July 25th, 1923, at the special request of the Minister of Health, an address was given to Members of Parliament by Dr. J. C. McVail on the subject of small-pox and vaccination. From the orthodox point of view it must be admitted that few men could have been better qualified for the task than Dr. McVail, who has made such a life-long study of the subject. The address has since been published as a propaganda pamphlet by the Research Defence Society, and in view of the importance of the occasion and the publicity given to it, it is desirable that it should be scrutinised somewhat closely to see how far the statements made and the arguments used represent the whole truth on this highly complex and debatable question.

Dr. McVail divided his address into four sections, each introducing a definite proposition: (1) Small-pox is worth preventing; (2) small-pox can be prevented by vaccination; (3) small-pox cannot be prevented without vaccination; and (4) properly conducted vaccination is very safe.

1. *Small-pox is Worth Preventing.*

Dr. McVail begins by pointing out that there are two very different types of small-pox—one mild, the American type; the other severe, the Asiatic type. As an example of the former he instances the recent epidemic at Gloucester with only two fatalities; whilst as an example of the severe type he instances the outbreak in the Poplar Workhouse in 1922. This outbreak, he observes, was exterminated by "vaccination and isolation."

This brings me to my first criticism. Dr. McVail was addressing Members of Parliament. The question, and really the only question which concerns them, is the necessity or otherwise of *compulsory infant vaccination.* To tell them, without qualification or explanation, that it was "vaccination" which, with isolation, exterminated the Poplar outbreak was, I suggest, distinctly misleading, though I do not suggest that Dr. McVail intended to mislead. I suggest that many of his hearers would probably think that by "vaccination" he meant infant vaccination. Yet, as Dr. McVail must admit, such vaccination had really nothing to do with stamping out the outbreak. The initial case, the inmate, H. W., who caused the whole trouble, had been vaccinated in infancy, and so had the great majority of the cases (at least 46 out of 65) which contracted the disease—directly or indirectly—from him. Of course, what Dr. McVail meant by "vaccination" was *emergency vaccination of contacts*—a very different matter—and he might have told his hearers that the very success of this kind of vaccination constitutes a strong argument against the need for infant vaccination. He might have pointed out how extraordinarily successful the emergency measures taken in the Poplar outbreak—prompt isolation of cases with vaccination and surveillance of contacts—proved; with the result that in spite of the very alarming nature of the outbreak—the congested locality right in the heart of the East End, the fatal strain of the disease, the exceptionally large number of contacts, and the great extent to which infant vaccination had been neglected in the district—it was got under complete control almost at once. He might also have pointed out that if the initial case (the man, H. W., who worked in the laundry of the workhouse) had *not* been vaccinated in infancy it is almost certain that the man would not have had such a mild and

modified attack, in which event it is very unlikely that the nature of his illness would have escaped recognition. Had it been recognised he would at once have been isolated, instead of being allowed to continue working and moving about the institution; the other inmates and staff would have been vaccinated at once, and the whole outbreak would have been nipped in the bud. In fact, Dr. McVail might truthfully have said that so far from the practice of infant vaccination helping to stamp out the Poplar outbreak, it may reasonably be regarded as the indirect cause of the whole trouble.

Dr. McVail goes on to refer to the ravages of small-pox in pre-vaccination days and draws a harrowing picture of what took place in Kilmarnock in the period 1728–64. He tells us that 16 per cent. of the total deaths were due to small-pox, as were nearly all the deaths of young children. Not content with stating cold facts, he proceeds to paint an eloquent and pathetic picture. Here is a sample :—

"In respect of small-pox there were indeed three Kilmarnocks. One consisted of the population living over 4 or 5 years of age. These were now protected against small-pox; they had already battled with and overcome the disease fiend. Many would be disfigured; some would have suffered from injury or loss of sight; some would be afflicted in various ways by the sequelæ of the disease, but they were practically safe from future attack. The second Kilmarnock lay under the greensward of the kirkyard. These had been in the same battle with small-pox, but had lost their lives and were at rest. The third Kilmarnock was that community of little children who had been born since the last visit of the pestilence. Within four or five years of birth they had to meet and fight the most terrible physical foe they would ever encounter. Human affection was as keen then as now, and I ask you to imagine what would be the feelings of a mother when she was told that the truce of God had ended, and that the town was again invaded by small-pox."

I feel bound to point out that such eloquence is really quite irrelevant and is nothing more nor less than an attempt to create prejudice (of course, this is not intended in an offensive sense). We expect this sort of thing from a clever barrister, paid to plead a cause, but it is hardly what we expect from a man of science like Dr. McVail. Dr. McVail knows quite well that the conditions in this country at the present day, as regards such a disease as small-pox, are so totally different from what they were two centuries ago that to imply, as he seems to do, that but for vaccination we should to-day be exposed to the same danger really amounts to special pleading. He might at least have pointed out that, coinciding with the perfection of modern methods of prevention, and in spite of the steadily increasing neglect of infant vaccination throughout the country, small-pox has become, during the past two decades, one of the rarest of the zymotic diseases, and the mortality caused by it has been negligible. He might further have pointed out that the American type of small-pox, which has now appeared in this country, and about which so much alarm has been raised in the press and elsewhere—which, indeed, was presumably the cause which had led the Minister of Health to invite him to give the address—had none of the terrible characteristics which he had been describing so graphically. There is practically no loss of life, no disfigurement, no injury to sight, &c.; and as for the feelings of the poor mothers, he might have said that instead of terror the disease is now apt to inspire only contempt, so much so that it is difficult to get people to treat it seriously.

2. *Small-pox Can be Prevented by Vaccination.*

This is Dr. McVail's second proposition. What exactly does he mean by it, or, rather, what would his hearers be likely to think that he meant by it? If he meant that small-pox can be prevented *in the individual* by vaccination and revaccination as often as necessary to keep the individual immune, then I quite agree with him. But if he meant, or if his hearers thought that he meant (as most of them no doubt would think), that small-pox can be prevented —i.e., effectually controlled—*in the community* by a State system of infant vaccination then I submit the proposition cannot be substantiated. Dr. McVail says that time will not allow him to submit all the world-wide statistics and experience, the accumulation of 120 years, on which *faith in vaccination* is based, but he will tell, as briefly as possible, the nature of the evidence on which medical confidence rests. "In whatever way the data are questioned, from whatever angle the problem is viewed, the conclusion is the same." Incidentally, I may remark that "faith in vaccination" is one thing; up to a point I have as strong a "faith in vaccination" as Dr. McVail himself. But faith that any system of infant vaccination will effectually control small-pox is quite another thing.

The points he adduces to support his proposition are as follows:—

(1) The mortality from small-pox has been much less since vaccination was introduced. He admits that this in itself proves nothing. The mortality of plague, cholera, and various other diseases has also greatly diminished. But he suggests that "a comparison of places and times of small-pox diminution side by side with vaccination affords strong proof of causal relationship."

(2) The altered age-incidence of small-pox. This, of course, is a perfectly sound argument for proving that vaccination confers temporary immunity against small-pox on the individual. I submit that it is no evidence whatever that infant vaccination protects the community against small-pox. It may simply shift the incidence of small-pox from one age to another.

(3) In countries which are well vaccinated and revaccinated there has been much less small-pox than where vaccination has been neglected. Dr. McVail cites as the "outstanding example" the case of Germany. He has to admit, however, that the recent position of that country is "interesting": I suggest that "disconcerting" would have been a more appropriate word. He then proceeds to explain why it is that Germany (which for years has been held up by provaccinists as the shining example of what can be done by compulsory vaccination and revaccination to abolish small-pox) has fallen so sadly from grace. In the six years, 1917–1922, he tells us, "the disease has attained quite appreciable prevalence." Nearly 11,000 cases of small-pox have occurred with a fatality-rate of 15·6 per cent. This is equivalent to *1716 deaths* from small-pox. He might have mentioned that in the same period the number of deaths from small-pox in England and Wales, without revaccination, and with infant vaccination seriously neglected, has been negligible.

We can only conclude from this that there is no longer a really outstanding example of a country which will support the thesis that "in countries well vaccinated and revaccinated there has been much less small-pox than where vaccination has been neglected." One may well ask, If Germany cannot protect herself by vaccination what country can?

Dr. McVail does not dare to suggest that in towns and localities in this country where vaccination has been neglected there is more small-pox than where the Vaccination Acts have been sedulously carried out. He knows well that he would have found it very difficult to substantiate this assertion. He knows that some of the best-vaccinated towns—e.g., Sheffield and Middlesbrough—have suffered from severe epidemics, and he knows, too, that there is at least one large town which has deliberately abandoned infant vaccination and yet has suffered no more than other towns from small-pox.

(4) In classes which have been well vaccinated and revaccinated there has been comparatively little small-pox. In support of this Dr. McVail cites the case of the small-pox nurses. Here, again, I quite accept the immunity of small-pox nurses as definite and convincing evidence that by vaccination (repeated as often as necessary) it is quite possible temporarily

o protect *individuals* against small-pox, but I submit mphatically that this is no evidence that infant accination will, or does in fact, protect the community. hus, small-pox inoculation would be equally effective though no doubt less satisfactory in other ways) in rotecting small-pox nurses, but Dr. McVail will ardly suggest that this would be any evidence that noculation would be effective in protecting the ommunity. Further, vaccination would still be uite effective to protect small-pox nurses even hough the immunity only lasted a few months, ut in that case no one would suggest that it would ave much effect in protecting the community.

(5) In towns where small-pox prevails more of the nvaccinated than of the vaccinated are attacked, specially if the vaccination is recent. This, I submit, gain, only proves that vaccination confers temporary mmunity upon the *individual*. It is no evidence that accination protects the *community*. Small-pox noculation would show the same effect.

3. *Small-pox Cannot be Prevented without Vaccination.*

Again it is necessary to ask just what Dr. McVail neans by this statement. He may mean (though doubt if the majority of his hearers would think hat this was what he meant) that it is impossible ffectually to control small-pox without having handful of vaccinated doctors and nurses to handle he disease and without vaccinating contacts. Even n this sense the statement is not really justified, ecause, of course, if there were no such thing as accination we could quite well protect our small-pox taff by inoculation, which would be equally effective f much less convenient. And as regards contacts, f these are kept under close surveillance it is very arely that they spread the disease, whether vaccinated r not. Vaccination of contacts renders valuable elp in reducing the total number of secondary cases, ut I submit that it is certainly not essential for the ontrol of the disease.

But if Dr. McVail meant that it is impossible ffectually to control small-pox without vaccination f the general population—and I suggest that this is he sense in which it is probable his hearers would nderstand him—then the statement is still less ustifiable. The whole trend of the evidence of the ast two decades tends to show that it is quite possible ffectually to control small-pox without recourse to eneral vaccination. Small-pox—at any rate the evere Asiatic type of small-pox—has been controlled ith such success, in spite of the increasing neglect of accination, that the mortality from the disease uring the past 18 years has ceased to be an appreciable actor in our vital statistics. Surely, the experience f places which have largely abandoned vaccination oints definitely to the same conclusion. It is rather emarkable that Dr. McVail made no reference in his ddress to the important experiment which has been arried on in the city of Leicester for the past 40 years. oes he really think that this experiment has no bearing pon the question at issue? He was not always so eticent. If he had been quite frank—if he had wished o put an impartial and unbiassed statement before is hearers instead of a one-sided propagandist tterance—he would surely have told them something bout Leicester's "gigantic experiment" (as a former ditor of the *British Medical Journal* called it) and of is own confident prediction that it would lead to nevitable disaster. He might have told them that n his classical work, "Vaccination Vindicated," ublished in 1887, in referring to the action of Leicester n setting the Vaccination Acts at defiance, he had ritten:—

> "The antivaccinators of Leicester . . . having to a great xtent thrown off the armour of vaccination, are waging a esperate and gallant, though misguided, conflict against he enemy. . . . But . . . in Leicester, when its time rrives, we shall not fail to see a repetition of last century xperiences, and certainly there will afterwards be fewer hildren left to die of diarrhœa. It is to be hoped that when he catastrophe does come, the Government will see that s teachings are duly studied and recorded. . . . Leicester has had little chance of getting its immunity tested. When another great outbreak occurs among the susceptible population of England it will be time enough to see how Leicester comports itself under the ordeal."

This was 36 years ago. At that time it was reasonable to suggest that there had been insufficient time for the experiment to be properly tested. It had only been in operation a few years. But this plea can hardly be put forward to-day. During the years which have since elapsed less than 10 per cent. of the children born in Leicester have been vaccinated. Small-pox has been repeatedly introduced into the city, both in the mild and severe forms, and there have been three epidemics. Yet in the 36 years, out of an average population of 200,000, there have been only 51 deaths, an average of less than two per annum. Certainly, there has been no "catastrophe" such as Dr. McVail expected. Compared with the experience of other large towns, such a result cannot be regarded as at all unfavourable. Indeed, compared with certain well-vaccinated towns, it is highly favourable.

I am not blaming Dr. McVail because his prophecy has not come true. He only believed what almost the entire medical profession at that time believed, and honestly believed. But having prophesied and lapse of time having proved his prophecy mistaken, it is surely necessary that he should reconsider the premiss on which he based his prophecy. That premiss was that it is impossible to prevent small-pox without vaccination. And yet we find him, at an important gathering of the legislators of the Realm, repeating this statement, as dogmatically as ever, and without any reference to his previous mistake. Let me ask Dr. McVail one question: Supposing the Leicester experiment had resulted as he expected it would result; would he have made no reference to it? Would he have regarded it as of no significance? I think not. The fact is that the experience of Leicester constitutes a very valuable "control" experiment, and the importance of the "control" experiment is well known to every student of science.

4. *Properly Conducted Vaccination is Very Safe.*

The safety of vaccination is Dr. McVail's last proposition, but he is careful to qualify the statement by saying "properly conducted." But if vaccination is not properly conducted, whose fault is it? Presumably, members of the medical profession, who alone perform the operation. That doctors are sometimes careless is just one of the risks attaching to vaccination which make parents object to it. But Dr. McVail may urge that one cause of danger from vaccination is that of dirt getting in after the operation. This again, in the crowded homes of the poor, must surely be regarded as one of the inseparable risks of vaccination. What consolation is it to the parent of a child who is suffering from a septic arm following vaccination to be told that it is not the vaccination which is to blame but the carelessness of the doctor or mother?

Dr. McVail says that the chief danger from vaccination feared a generation ago was that syphilis might be conveyed by arm-to-arm vaccination, but he omits to mention that this danger was strenuously denied at that time by the medical profession; or that the Local Government Board actually issued a pamphlet, since withdrawn, entitled "Facts Concerning Vaccination for the Heads of Families," in which it was confidently asserted that "the fear that a foul disease may be implanted by vaccination is an unfounded one." Dr. McVail admits that the late Jonathan Hutchinson proved that the danger of syphilis being conveyed by arm-to-arm vaccination was a very real one, but he points out truly that by the substitution of calf lymph for human lymph this particular danger has been entirely overcome. He omits to mention, however, that many doctors believe that calf lymph is more apt to cause "bad arms" and severe constitutional disturbance.

Dr. McVail goes on to say that "nothing in the world is absolutely safe. A scratch of a pin may open

the door to erysipelas or lock-jaw, . . . and the vaccine vesicle may become infected septically or by erysipelas as in the case of any other wound. Such accidents, however rare, are most deplorable, and even if they are due to the fault of the incompetent or careless mother there cannot but be the deepest sympathy for her baby or herself." Incidentally, one wonders in what proportion of vaccination accidents the unfortunate mother can fairly be blamed, bearing in mind the conditions existing in poor homes? But I will let that pass. Dr. McVail might have mentioned to his hearers in this connexion a series of disasters which occurred in the State of New York a few years ago as a result of which it was decided by the State Legislature virtually to repeal the enactment which made universal vaccination compulsory.

Dr. McVail might properly have pointed out also that whilst the *proportion* of vaccinal injuries may be small, yet in the aggregate they are far from inconsiderable; and that now the risk of small-pox has been so enormously reduced the relative risks of vaccination and of small-pox may reasonably be compared. He might have mentioned that it frequently happens that the annual deaths resulting from the effects of vaccination actually exceed the deaths from small-pox. Indeed, if he takes the last 18 years, 1906–23, he will find that the deaths of unvaccinated persons from small-pox have been less than the deaths from vaccination. I think that this fact would have surprised some of his audience.

Just one more point before I conclude. Dr. McVail says, on p. 13: "In Britain, indeed, vaccination has never been 'compulsory.' Such a title is a misnomer. The Acts have never sanctioned a child being taken from its mother's arms and forcibly vaccinated." Surely, this is a verbal quibble hardly worthy of Dr. McVail! At one time vaccination was as "compulsory" as it was possible for a determined administration to make it so. In one city alone (Leicester) there were 1154 prosecutions in a single year (1881) and by the year 1886 the total number had mounted up to over 6000. Of the parents prosecuted 64 were imprisoned (after refusing to pay fines), 193 suffered distress warrants upon their goods, whilst a sum of £2388 was levied in fines and costs. If this was not "compulsion," what was?

Conclusion.

To summarise the chief of the above criticisms:—

1. In contending that small-pox is worth preventing it is quite irrelevant to cite the ravages of small-pox two centuries ago. However interesting historically, such facts have really no practical bearing upon the problems facing sanitarians to-day. In those remote times the principles of modern preventive medicine were neither understood nor practised.

2. The serious outbreak of small-pox in Poplar Workhouse last year, so far from being an argument in favour of infant vaccination, illustrates very remarkably one of the chief drawbacks to such vaccination—viz., its tendency to encourage the spread of small-pox by masking its true nature.

3. The statement that small-pox can be prevented by vaccination is true in the sense that vaccination has the power of producing temporary immunity to small-pox in the individual. But it has never been proved that small-pox can be prevented—i.e., effectually controlled—by any system of infant vaccination, however thorough. All the arguments adduced by Dr. McVail to substantiate this part of his case in reality only prove that vaccination produces temporary immunity in the individual.

4. It is very doubtful whether the statement that small-pox cannot, or could not, be prevented without vaccination is justifiable. The experience of this country during the past two decades, since modern methods of dealing with disease have been in vogue, certainly appears to point to the opposite conclusion.

Dr. H. H. Taylor, of Hove, has been placed on the Commission of the Peace for the borough.

CHANGING FACTORY CONDITIONS:

RISING STANDARDS AND FUTURE DEVELOPMENT.

I.

THE present Factory Act, which marked a great advance upon any of its predecessors, has now been in operation for over 20 years, and a good many changes have been effected under its powers. They have been 20 years, moreover, of remarkable developments in other directions, and they have witnessed the rise of voluntary agencies and of voluntary movements which are affecting profoundly industrial life. They would in any case have been years of unusual importance because they include the years of the war, which left a deep mark upon industrial life as upon every department of human life throughout the world. It is therefore suitable that some attempt should be made to review the changes which have taken place and to note present-day tendencies. This is the more important in view of the likelihood of the introduction of a new Factory Bill at no distant date.

The Rising Standard of Health.

The health of the workers, of some sections more directly than of others, has been an object of factory legislation from the time of that first modern industrial enactment, the Health and Morals of Apprentices Act 1802, passed six years after the Manchester Board of Health (a voluntary association) had called attention to the injurious effects on young children of work in the cotton mills. Regard for health was one of the main arguments for the limitation of hours in respect first of children and later of women and young persons; and limitation of hours was in effect the only measure proposed for many years. It was not until 1844 that the fencing of shafts and of gearing was required in the interests of the safety of workers; it was another 20 years before a Factory Act contained any provision as to sanitation and ventilation, and then the Act, that of 1864, only applied to certain trades which were considered to be specially unhealthy. The beginnings of control over sanitation are to be found in the Public Health Act of 1848, but it applied only to a few populous centres. The Public Health Act of 1866 gave a wider supervision. But it is worth noting that right up to 1901 there was no statutory provision as to general ventilation in factories, as distinguished from the removal of dust or fumes engendered in a process of manufacture. Nor to this day is there any general provision as to lighting.

Factory legislation has gone along two main lines; there has been a steady growth of provisions for general well-being, covering more and more conditions and extending to more and more categories of workers. And at the same time there has been special attention paid to unusual dangers to health or to safety, or to the necessity of protecting classes of workers most likely to suffer. Along these lines there has been substantial progress. It may be assumed that there will be in the future, as there has been in the past, need for both general and intensive study and for both general and special supervision of factory conditions.

The Dangerous Trades.

Legislation for trades especially dangerous to health dates back to 1864, when employers in them were given the power of making regulations for their workpeople, subject to the approval of the Home Office, and of enforcing them by fines, a measure which would meet to-day, it may be assumed, with most strenuous opposition. The making of regulations was transferred to the Home Office by the Factory Act of 1891, and the powers given then and increased in 1901 are the basis of the very complicated code of special regulations applying to dangerous trades to-day. The compulsory notification of industrial poisonings began in 1895, so that from that date we have fairly reliable statistics by which to gauge the

success of the regulations. The yearly returns form clear evidence of a substantial improvement, for whilst notifications are certainly not less complete than they used to be, and whilst the list of diseases notifiable has been extended, the number of cases shows a marked diminution in an increasing population. Phosphorus poisoning has practically disappeared; arsenic poisoning has been reduced to very small dimensions; and whilst the figures relating to mercury are not quite so satisfactory, they compare very favourably with pre-war years. Anthrax still remains a very serious danger, both here and abroad, and it is receiving careful consideration from the staff of the International Labour Office. Toxic jaundice, made notifiable in 1915, was almost entirely a war disease and it has disappeared with the war. As to the two industrial diseases recently made notifiable, chrome ulceration and epitheliomatous ulceration, it is too early to speak. But the poisonings already mentioned are, of course, all of them put together small in the total number of poisoning cases, of which a preponderating number still are, as in the past, due to lead. It is very satisfactory to note that the number of cases of lead poisoning notified has been reduced to something like a quarter of what it was in 1900. It is not the case, unfortunately, that the number of fatalities has diminished in the same proportion; there were 26 fatal cases in 1922 and 23 in 1921, as against 38 in 1900 and 31 in 1899. On looking into the detailed figures it is obvious that whilst in most of the industries employing lead it has been found possible to reduce immensely the amount of ill-health and the number of fatalities, in one particular industry—namely, the making of china and earthenware—there has been as yet no substantial reduction. There is also grave reason to be uneasy about the continued prevalence of lead poisoning among house painters and plumbers, who do not, however, come within the scope of the Factory Act.

Very wide powers are given to the Home Office under Section 79 of the Factory Act, and codes of regulations are in force in about 40 different trades, with yearly addition to the number. The commonest requirements are exhaust, or other special ventilation; the supply of protective clothing, which in many cases includes respirators; the provision of washing facilities, and in a few cases of baths; of cloak-rooms and of mess-rooms. Special attention to the cleanliness and good repair of floors is often required. Periodic medical examinations are ordered in some dozen trades. Women are excluded from a few processes,* young persons from a good many more.† In three cases work is only allowed on certain processes for short spells: they are the use of carbon-bi sulphide in the india-rubber industry, work in dry chambers and condensing flues in lead-smelting, and dipping and one or two other processes in pottery. It is worth noting that the limitation of hours applies to men as well as to women and young persons. Among regulations in different industries we have insistence on the provision of first-aid boxes where, as in work on chemicals or on horsehair, cuts and sores might easily be poisoned or infected; but, so far as health is concerned, the kinds of regulations mentioned cover substantially the field. They do, speaking broadly, enforce a special and detailed attention to hygiene in those trades where the penalties of neglect would inevitably be severe.

Welfare Orders.

In the stress of war, when the substitution of women for men and the urgent call for rapid production opened the eyes of many people to the need for conditions in the factories more favourable to health and to efficiency, there passed through Parliament, with little notice and practically no opposition, an Act with a curious title, the Police, Factories, &c. (Miscellaneous Provisions) Act, which gave new and far-reaching powers to the Home Office. For the first time they were able to prescribe conditions of welfare, as distinct from general safety and sanitation, even in the absence of any special danger; and there began to be built up for different industries a series of orders similar to those which had come into force during the past 25 years in the "dangerous trades." Welfare Orders have been made so far for about 15 trades. Provision of cloak-rooms and of mess-rooms, of protective clothing, and of first-aid boxes, are the most common requirements. In one or two industries—e.g., in fruit-preserving—seats must be provided, in some processes for all workers, in other processes for women only. For those who are engaged in the gutting of herrings there must be a rest-room. By one of the earliest orders under this Act there must be in *every*‡ factory a supply of drinking water.

Changes in Administration.

It is one thing to pass laws and to make regulations, and quite another thing to get them carried out. The changes in the administration of the law have been at least as important as the changes in the law itself. There is the increasing specialisation of the factory inspectorate, the doubling, for instance, of the medical staff since 1910, and the appointment of the first woman medical inspector in 1921. There has been an immense growth of coöperation between the factory inspectorate and the organisations of employers and of workers. In the annual report for 1922, Dr. J. C. Bridge records an interview with the officials of the Dyers' Union, Leicester, with regard to the Chrome Dyeing Welfare Order:

> "One of the main objects of the interview, as put forward by the officials, was that they wished to be in a position to explain to their members the use that should be made of the provisions of the Welfare Order. For this reason, he considered the interview very valuable, for one of the difficulties of administering the Welfare Orders is that the men fail to take advantage of the provisions made under them. An attitude such as that shown by this Union marks a very great advance."

Such an advance is being made in many quarters. If the briquette makers of South Wales, who are liable to pitch-cancer, are making any use of the baths provided, and are submitting to a periodical medical examination, it is due to the persistent advice given to them by their trade-union leaders. (In this particular case the regulations are merely by agreement of the Home Office with those engaged in the industry; they are not yet statutory.) It would be possible to cite many more instances of this kind. It means in many cases that the work done by the Joint Industrial Councils of some industries brings an intelligent and whole-hearted compliance with regulations which might otherwise be largely inoperative.

The Influence of the War on Welfare Work.

Welfare work, as distinct from statutory provision for welfare, had existed in a minority of factories for many years before the war, but it was the war which brought it into prominence, made it widespread, and gave to the welfare supervisors the status of a profession. The trade depression, as well as the relaxation of Government pressure, have produced a set-back, but there can be little doubt that it is only temporary or as to the far-reaching effects produced upon the health of the workers. It is in itself a very great thing for the women and girls to have a well-educated woman in a place of authority; she will attend to a hundred details, separately perhaps quite small matters but cumulatively of importance, which were neglected in the past because it was no one's special business to look after them. It may seem to some a trifle that there should be a woman responsible

* *Women* are excluded from casting brass, from some processes in the manufacture of electric accumulators, from smelting lead, the manufacture of paints and colours, and some processes connected with pottery.

† *Young persons* are excluded from the manufacture of chromates, some processes in the manufacture of electric accumulators, vitreous enamelling, use of non-disinfected horse-hair, fume processes and lead processes in the manufacture of rubber, smelting lead, dipping, and other processes connected with pottery, tinning of hollow ware, and heading dyed yarn.

‡ Unless it employs less than 25 persons.

for the proper condition of the sanitary conveniences, but those who have any knowledge of the habits of factory girls or of the evil effects of chronic constipation, will not think so. It is a matter of importance, too, that there should be someone on the look-out for marks of over-strain; that there should be a woman to whom the women can talk freely; and that there should be a rest-room where women and girls can go at those times when a short interval wisely spent can make such a difference. There are many other things which the welfare supervisors do which have a marked effect upon health; they are responsible for seeing that the workers can get a good meal at a reasonable price, and in comfort; they should arrange also for convenient means of transit where the workers come from a distance. There are also benefits, such as free dental treatment, given by some firms, but they are exceptional and probably they are likely to remain so; responsibility for the care of the teeth of its workpeople cannot be expected to fall normally upon a firm.

The Reduction of Hours.

The greatest of all the changes which have taken place in factory life in recent years has been the almost universal reduction of hours which took place in the months following the Armistice. In about six months six million workpeople had their normal weekly working hours reduced by an average of about six and a half hours per head. It was a very remarkable social phenomenon, this yielding without coercive legislation and without a bitter industrial struggle, of claims which had been vainly made and stoutly resisted for at least half a century. War-time experience had wrought a notable conversion of the employers. There had been a huge sale of the memoranda issued by the Health of Munition Workers Committee, and their findings had been written up in scores of newspapers and magazines. In December, 1918, in countless factories, great crowds were swarming through the gates at 6 A.M., to pour out again at 6 P.M., as they had done for decades past. By Easter 1919 this was exceptional.

Of all the conditions injurious to health from which our industrial workers have suffered the most common and one of the most serious has been continued overwork. On this point the final report of the Health of Munition Workers Committee was emphatic:—

> Apart from exceptional occupations which are in themselves injurious, the principal of the undesirable conditions, the most radical and persistent, the commonest is that of *long hours*.

Sir James Paget is quoted:—

> "You will find that fatigue has a larger share in the promotion or transmission of disease than any other single causal condition you can name."

At the same time as hours were shortened, there came in many cases automatically a curtailment also of the length of spells of work; and there has been a growing recognition of the value, strongly emphasised in the report just quoted, of rest-pauses. But spells of work are still in a good many cases excessively long.

Child Labour.

Another change amounting to a reform came by legal enactment and not without a certain amount of opposition: children disappeared at last from the factories. The injury done to boys and girls by premature work had been deplored and denounced a thousand times, and it had been greatly diminished by successive enactments. The Women, Young Persons, and Children Act of 1920 put an end to it, and within two years of its passing there was no longer a half-timer in our factories. We are still putting an excessive strain upon many of our adolescents, but that is another matter.

To sum up, there has been a steady raising of the standard of precautions in the dangerous trades, and the results are very evident in the statistics. There has been more recently a marked advance in the practices of a number of trades which, whilst not dangerous, have yet peculiar conditions. And there is a growing attention being paid, and a new scientific study being made, of the general conditions of welfare in the ordinary factory. More especially hours of work are much shorter than they were. Credit for the improvements is due partly to factory legislation and its administration, partly to voluntary agencies, and a changing public opinion. The results must be looked for in later years in the general health and mortality figures of different occupations and of the whole nation.

THE BRITISH EMPIRE LEPROSY RELIEF ASSOCIATION.

ON Jan. 31st a meeting was held at the Mansion House to open a campaign on behalf of the 300,000 lepers in the British Empire. The Lord Mayor presided. It is hoped to raise a fund of £250,000 for the purpose, and donations of £100 from the King and £100 from the Prince of Wales were announced. Messages were read from the Prince of Wales and from the Viceroy of India (Lord Reading).

Lord Chelmsford (chairman of the Association) outlined the situation that led up to the formation of the Association and emphasised the Imperial character of the latter. He urged business men to look upon the Association as a piece of health work for the Empire and to accord it the support it deserved.

Sir Humphry Rolleston said that leprosy, now very rarely seen in this country, was therefore apt to be out of mind; but as the greatest colonising Power in the world it was our obvious duty to set an example of preventive medicine. This country was now practically free from the disease, there being only one, a very small, though attractive, leper colony—that of St. Giles, near Chelmsford, which was in urgent need of funds; but it was once a very different story, for in the fifteenth century there were said to be 19,000 leper hospitals in Europe, including 2000 in France and 200 in England, and although many of the inmates were no doubt suffering from diseases erroneously regarded as leprosy, those figures gave some idea of its prevalence.

The Danger of Undetected Cases.

The unfortunate victims of this slow but hitherto remorselessly progressive disease became terribly mutilated and suffered both in body and in mind. In the dark ages they were pariahs; such isolation, no doubt in association with other factors, helped to diminish the spread of the disease, but the unhappy plight of recognised lepers had naturally always made them try to hide their disease. Even now this concealment was one of the great difficulties to be contended with in its prevention; in India, for example, although officially there were 102,000 lepers in 1921, there was reason to believe that there were at least as many more undetected. Leprosy was now known to be contagious and not hereditary, but the disease took years to develop after the seeds had been sown; the young were specially likely to contract it, so that an unrecognised case in a parent might infect the young family. Prevention was better than cure; in order to remove the natural dread of isolation from simple-minded and suspicious natives the conditions of segregation must be rendered attractive instead of repulsive, and leper colonies holding out pleasant, instead of prison-like, conditions of life must be provided. This was already being done in India, but only 8000 of the known 102,000 lepers were at present receiving help in this respect. Segregation alone was not enough to stamp out the disease; to detect the earliest stages and to test out the newest remedies required further research and therefore endowment. It was 50 years since Hansen published his discovery of the leprosy bacillus and this jubilee should surely be celebrated by its final disappearance. How was this to be effected? There appeared to be good reason to believe that Sir Leonard Rogers had found in the fatty acids of certain oils and in the preparation called

morrhuate of sodium a remedy that bade fair to be a final cure. Further work remained to be done; it was not always that the right man and the means for such success were available, and it was therefore obviously up to them to give him the full opportunity.

Development of the Use of Chaulmoogra Oil.

Sir Leonard Rogers briefly outlined the researches which enabled him to establish the important principle that by the injection of soluble products of the active portions of the old Indian remedy for leprosy, chaulmoogra oil, the bacillus of the disease could be destroyed within the body, with clearing up of all symptoms, as well as of the infectivity of the disease, and that similar preparations derived from cod-liver and other oils were also effective in leprosy. An American chemist in Honolulu later introduced a slightly different and more convenient product of chaulmoogra oil, which had now been used successfully for several years in various countries; the latest report from the Philippines of a trial of these various preparations in 1067 cases showed 56 per cent. improved, and in 36 per cent. more showed arrest of the disease, while where injections had been continued for the necessary periods of 6 to 9 months 74 per cent., and after 12 to 15 months no less than 93 per cent. of cases showed definite improvement, and a number had been completely cleared up. Numerous cures, in the very practical sense of restoration to health and working power, could now be obtained, while as some of his early cases had remained well for from six to eight years, there was good reason to believe that permanent cures could be established, an immense advance having already accrued in the treatment of this hitherto intractable disease.

Confidence of Natives in the Treatment.

To those who had had much experience of medical work in India and other tropical countries, he said, equally conclusive evidence was furnished by the fact that in many places numerous lepers were willingly submitting to weekly injections for many months, although such races would not continue a troublesome treatment unless absolutely convinced of its very beneficial effects. In leprosy, however, as in tubercle, much caution was necessary in speaking of a cure, and relapses had occurred due to not continuing the treatment for some time after the symptoms had disappeared. Nevertheless some of his earlier cases had remained well for six to eight years, so there was good reason to believe that permanent cures could be obtained, although, of course, lost fingers could not be replaced, and there was a definite limit to the efficacy of the treatment in long-standing and advanced cases, although photographs recently received show astonishing improvement even in some of the most advanced nodular cases. Apart altogether from the still incompletely settled question as to what proportion of lepers could be cured, to the important extent of losing all symptoms and infectivity and being restored to health and usefulness, the recent advances were rapidly removing the greatest obstacle to the reduction of leprosy by the segregation methods hitherto almost entirely depended on—namely, the impossibility of finding and isolating lepers in the early stages of their disease, before they had infected other members of their households.

Sir Leonard Rogers considered that from the point of view of the reduction and eventual eradication of leprosy from British possessions, an even more important outcome of the recent advance was already evident—namely, that for the first time in the 3000-year-old history of leprosy, large numbers of lepers were coming forward in the early and more amenable stages of the disease and the clearing up of their symptoms and infectivity was being accomplished in Calcutta in an out-patient clinic at low cost, before they had infected another generation of their households; thus there was a possibility of reducing the prevalence of the disease more rapidly than ever before, if only funds were forthcoming to bring the remedial measures medical science had at length furnished, within the reach of the 300,000 or more lepers in the British Empire, not more than one-fifth of whom could now be receiving the improved treatment, mainly on account of the poverty of India, tropical Africa, and others of our most affected possessions.

The Work of the Association.

The British Empire Leprosy Relief Association would work largely through existing agencies in distributing drugs, information regarding their use and the latest medical advances, by helping sound schemes of segregation combined with the latest treatment, training the staffs of leper institutions, and supporting research for still further improving the treatment, which fails to completely clear up many advanced cases; in short, to coördinate treatment and research throughout our scattered possessions. The recent advances were due to British and American investigators, but at present only the Americans were supplying their blessings to the great majority of their lepers in the United States, Hawaii, and the Philippines. As the 1923 Strasbourg International Leprosy Congress passed a unanimous resolution that all lepers segregated for the benefit of others ought to receive the best possible treatment, a moral obligation lay on Great Britain to fulfil this obviously just and urgent demand.

Mr. Frank Oldrieve (secretary of the Association) said that in India last year he saw more than 1100 lepers under the new treatments for the disease, and the majority were recovering. They might look forward to the Empire being practically free of leprosy within 30 years. Three points were to be stressed: (1) Segregation was effective in reducing the incidence of the disease; (2) leprosy was not hereditary; (3) leprosy was now curable. There was only the present generation of lepers to be dealt with. This was the most hopeful of all campaigns, for they were on sure ground and definitely knew what to do.

Sir Sydney Olivier, in moving a vote of thanks to the Lord Mayor, compared the discovery of the new treatment of leprosy to the establishment of the sources of infection in malaria and yellow fever. As Secretary of State for India he ventured to point out to his Indian friends, who had a large body of very able medical men, that they had an enormous opportunity, which had only recently been opened out to them.

NOTES ON THE FRENCH MILITARY HEALTH SERVICES.

(FROM OUR OWN CORRESPONDENT.)

THE French military health services are passing through a period of crisis which has arisen since the war and is due to the diminution of its personnel. The recruitment of French military doctors has, in the past, been carried out through two channels. (1) The first was the special Army Medical School at Lyons, to which admission was gained on a competitive basis. The course consisted of four years' study, and the same medical programme was followed as for the civil students at the Faculty of Medicine of Lyons, except that military discipline was enforced in the school. On qualifying, graduates were sent to the Val-de-Grâce, Paris, for a year's study of medicine in its application to the military health services. (2) The second channel was direct entry to the Val-de-Grâce by competition, open to doctors who had taken medical degrees elsewhere than at the Lyons School. On entering the army, the military doctor attained the rank and prestige of a combatant officer. Before the war these conditions were eminently satisfactory, competition was keen, and the best type of efficient army doctor was obtained, but at the present time the situation is completely changed. Pay has not risen in proportion to the cost of living, and the course of study required is long and costly. As six years are required in preparation, the army doctor, even if he starts his studies at an early age, cannot hope to commence his career before the age

of 25, while combatant officers from Saint Cyr or other military academies may attain a rank equivalent to his own at 20, after two years of study. And, on the other hand, a comparison with a medical man's prospects in civil life shows that the civil doctor's income at least bears some relation to the fluctuation of prices. The result has been that a considerable number of military doctors have left the service, and fresh recruits are not forthcoming. At a recent competitive examination at Lyons there were only half as many candidates as there were posts to fill. Such has been the experience every year since the war.

The Army Parliamentary Commission, realising the inadequacy of the pre-war system under present conditions, has abandoned the scheme of regimental service whereby one doctor was attached to one unit, and has instituted a medico-chirurgical service for each town, thus placing one medical officer in charge of several units. But it is too much to expect that one army doctor, however conscientious he may be, can alone give wholly adequate attention to several and perhaps widely separated units. Further, the doctor, in collaboration with the regimental commanders, played an indispensable rôle in dealing with all questions of hygiene, and it is now feared that his widened sphere will cause dilution of his influence, and the medical aspect of the army service will be weakened. In a country like ours, where military service is compulsory, everyone should have the right to adequate medical attention while in the army.

To meet the present crisis recourse has been had to civil doctors, who have been offered appointments at the various centres. But that is only a half measure, and cannot be more than temporary. The army needs permanent advisers on all health matters, who by their intimate and specialised knowledge of army conditions can maintain the highest standard of physical efficiency among the troops. In order to attract medical men to the army, and to retain those who are already in service, it has been proposed to add a substantial monthly bonus to the present rates of pay. It is to be hoped that this proposal will be carried into effect as soon as possible, in order to avert any further dissatisfaction.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A Surgical Lecture on "Dichotomy."

ONE must go back very far in the history of the medical profession to encounter an incident similar to that which happened a short time ago when Prof. Dr. Hochenegg, the well-known chief of the first surgical clinic of the Vienna University, launched a deliberate attack on the ethical standard of the Vienna doctors. In the course of a lecture, held before his regular audience of students, the professor declared that one of the most important principles of medical art was the correct indication for operations, and he was forced to state that in this respect the medical profession of Vienna was lacking in an unbiased consideration of deciding factors. He possessed proofs, he said, that monetary considerations were of paramount influence in deciding whether surgical interference be advised or carried out in the case of any particular patient. The disgraceful custom of "dichotomy"—splitting the fee between the family practitioner and the consultant or surgeon—had become lately so widespread and so widely accepted that those few upright men who refused to be a party to such proceedings were simply shut out from consultative work, and their practices, like his own, had dwindled away. Consultants who employed "agents" at a commission varying from 30 to 50 per cent. were flourishing and were praised as masters of their profession, while those who would not countenance "dichotomy" were held to be incompetent, antiquated, and incapable of doing any modern surgery. This disgrace Prof. Hochenegg would not tolerate any longer, and as he too had been the victim of rumours of having become quite unfit for surgical work, he exposed the intrigue to his students and also took care to communicate his lecture to the press. Needless to say, when the article appeared in the papers it caused a great outcry both amongst the profession and the general public. The Medical Council and the Economic Organisation both held protest meetings against the insinuations contained in the lecture. The professor was asked to show his proofs, and to state the names of the men who had acted in this shameful manner, otherwise he would be prosecuted for slander. The professor at first refused to hand over the material of his lecture to the authorities, but at last he was forced to give in, and within a fortnight he will have to sustain his attack on the profession with definite figures and names.

The First Year of Cremation in Vienna.

The first report of the Cremation Institute of Vienna was published recently, and it is very interesting to note that in spite of both open and secret opposition it could not only hold its own but even contribute to the finances of the municipality. Whilst at first the Government, whose leader is a Roman Catholic priest, was most violently opposed to the idea and tried to prevent the erection of the institute by every means at its disposal, it now limits its antagonistic attitude to a passive resistance. But the priesthood of both the Catholic and the Jewish creeds are openly hostile still, and refuse the religious ritual at the burial of a cremated body. Nevertheless, in the first month of last year, when the institute was opened, 30 cremations took place, and the number increased monthly until in December it reached the figure of 89. Altogether 834 corpses were cremated (519 males, 315 females). As regards religion, 517 were Catholics, 124 Evangelic, 95 Jewish, and the remainder were undefined. The original calculations were based on an average monthly record of 50 cremations, those actually effected constitute 5 per cent. of all burials in Vienna. If, however, we consider that a large number of burials take place at the expense of the municipality as "poor" burials, we find that nearly 10 per cent. of all burials paid for are cremations. The capital invested in that institute brings an interest at the rate of 25 per cent. per annum.

Medical Certificates of Exemption.

Physicians are often requested by their patients to supply a certificate stating that the patient is unable to attend school or to fulfil certain duties—e.g., as a witness in court, &c. This "desire to be ill" is often so pressing that the doctor complies with the patient's wish and provides a certificate in which the reasons for exemption are very often only an exaggeration of trivial symptoms. In a memorandum to the profession the Medical Council issues a warning to doctors with regard to this practice. The Austrian law does not at present deem such conduct to be illegal, but under the proposed new Medical Act the doctor would incur the danger of being charged with fraud if he were to give a wrong statement "knowingly." If the statement is used to obtain any material advantage—damages for an injury or free treatment under the "War Invalid's Act"—the doctor may be sued for damages by the second party wrongly charged. The minimum danger for the doctor would be of arraignment before the Medical Council for breach of the ethical code.

UNIVERSITY OF MANCHESTER.—A bronze bust of Prof. Harold B. Dixon, who occupied the chair of chemistry at the University from 1886 to 1922, was unveiled on Feb. 1st in the chemical theatre of the University by one of Prof. Dixon's earlier pupils, Dr. Harold G. Colman. Prof. Dixon said that it had been his ambition to complete the work of his predecessors, Frankland and Roscoe, and to secure facilities of research. Thirty-six years ago the facilities for research were practically confined to the big German laboratories. Our industries require recruits with training in methods of research, and the memorial he had striven for was the reputation of the laboratory of the University as a school of research. Individual subscribers to the Dixon memorial number 240, and the sum subscribed was £550, of which about £500 would be available for the bursary which it was proposed to found in honour of Prof. Dixon.

"Audi alteram partem."

A NEW TECHNIQUE IN RADIUM THERAPY.

To the Editor of THE LANCET.

SIR,—From the nature of the radiations emitted by the later disintegration products of radium it was thought that preparations of these later products alone, and without any of the more active members of the series, might have a specific action on superficial lesions. It has been found possible to prepare quite suitable applicators, and initial clinical experiment has so confirmed the expectation that we desire to make this preliminary notice of the work.

The diseases which have so far been treated with these preparations are: superficial nævus of the telangiectatic type and lupus erythematosus. Within a short time a very definite reaction has resulted with each disease. Part of an extensive superficial nævus showed marked improvement within ten days, with final pallor over the area of application. In a very intractable case of lupus erythematosus the reaction was most pronounced, and an apparently healthy area of natural colour was produced.

The results so far obtained are very encouraging, and work is being continued both on the methods of extraction of the particular active material and on the therapeutic use of such preparations. It is hoped to publish at a later date full details of the processes involved, and of all the clinical results.

We are, Sir, yours faithfully,

W. HERBERT BROWN, M.D.,
Dermatologist to the Victoria Infirmary, Glasgow;
JOHN P. MCHUTCHISON, B.Sc., M.A.,
Physical Chemist to the Glasgow and West of Scotland Radium Committee.
University of Glasgow, Jan. 23rd, 1924.

*** The collection of emanation residues is a matter of no little economic interest.—ED. L.

AIR NAVIGATION AND THE SCOPE OF PREVENTIVE MEDICINE.

To the Editor of THE LANCET.

SIR,—Travel has ever been a potent factor in disease propagation; a perusal of the history of medicine bears graphic witness to this fact. The Black Death which ruthlessly traversed the trade routes of the world in the Middle Ages might well be instanced; or, again, the cholera epidemics of 1817, 1826, and 1891, with India as their starting-point. To cite a recent example, the outbreak of small-pox in London in October, 1923, was traced to a woman traveller from Valencia in southern Spain. These are but isolated examples, chosen from memory and with due regard for brevity. It is of interest to speculate in regard to the spread of disease by air travel, and the measures which might be found necessary for the effective prevention thereof.

Some 20 years ago, the first power-aeroplane was flown for 12 seconds by Wright in America. To-day our aeroplanes have attained a speed of 250 m.p.h., have flown to a height of seven miles, and have remained in the air for a continuous period of 36 hours. Future progress may be as rapid. At the Imperial Conference held in London, October, 1923, the Air Minister stated that in the past three years our cross-channel air service had met with no serious accident, although 2,000,000 miles had been flown. The number of passengers was steadily increasing. Sir Samuel Hoare then proceeded to explain the Burney scheme to the Conference. This scheme proposes the opening up in the near future of an airship service between this country and India. The French Air Ministry has recently promised financial support to the proposed inauguration of an airway between Paris and Buenos Ayres. The International Air Navigation Commission, with headquarters in Paris, is at work preparing schemes, conventions, and maps, in the confident anticipation of the early establishment of these and other great airways.

In connexion with the International Commission a special medical subcommission has been duly set up, to deal presumably with the momentous medical problems which generalised air travel will bring to light. The work of such a subcommission should proceed principally along the channels of preventive medicine, so as to organise a line of defence against importation of disease through the medium of air travel. The vigilance practised by sanitary authorities at our seaports will require to be exercised in even greater degree at the great airports of the future. The danger of the propagation of disease by air travel is real. Cholera, for example, is a disease whose rate of spread coincides faithfully with the speed of human travel. Epidemics of this disease select India as their usual starting-point. Now an airway to India (as outlined in the Burney scheme) would allow of the completion of a journey in five days that now occupies 15 days. Again, travellers by air will complete long journeys within the limits of the incubation periods of certain infectious diseases which at present manifest themselves during the sea-voyage. Disposal of excreta on board airships may present difficulties. In the case of shipping Nature provides an effective means of disposal. In the case of aircraft performing long journeys a conservancy system will have to be devised.

The medical problems arising out of popularised air travel will constitute a new branch of public health work. Work of such a civil air medical service might comprise, inter alia, the medical inspection of all travellers by air on embarkation and disembarkation; the rigorous medical examination of all intending pilots or crew of aircraft; the periodical re-examination of such pilots and crew; the direction of sewage disposal; the periodical fumigation of large aircraft; the maintenance of adequate medical equipment on board aircraft. Many other duties could devolve upon such a service.

I am, Sir, yours faithfully,

ARTHUR MASSEY, M.B., Ch.B., D.P.H.,
Jan. 31st, 1924. Asst. M.O.H., Southampton.

THE "ELECTRONIC REACTIONS" OF ABRAMS (E.R.A.).

To the Editor of THE LANCET.

SIR,—There are at present only a few medical men in London who have faith in the E.R.A., and many others who have followed the articles in the American journals have more than a shade of scepticism.

The able article in THE LANCET of Jan. 26th by Dr. Howard Humphris, and the leading article in the *British Medical Journal* of the same date, have increased the number of sceptics. Everyone would welcome a real test of the diagnostic power of the Abrams machine and its modifications, leaving the question of treatment out of the inquiry, as many conditions are benefited by suggestion, and suggestion acts more powerfully when it is directed by means of some appliance not understood by the patient. The test I would suggest is that three of the exponents of this cult be selected to meet a like number of medical men chosen by yourself. The blood should be taken from each of the three "controls" (or ought I to say mediums?) of the followers of Abrams, and these specimens should be shuffled in with specimens of blood taken from patients with known and well-recognised diseases. These E.R.A. practitioners should report on the series of bloods, not knowing their sources, when, as their "controls" are presumed to be fairly healthy, the results might be interesting.

I am, Sir, yours faithfully,

BRUCE BRUCE-PORTER.
Grosvenor-street, W., Feb. 4th, 1924.

THE EXPLOITATION OF NURSES.

To the Editor of THE LANCET.

SIR,—A protest should be made against an apparent exploitation by the General Nursing Council of the mute, but not inglorious, army of women who are entering the nursing profession. At present a trained nurse has to pay a registration fee of one guinea and an annual half-crown to keep her name on the register. Now, it is proposed to charge impecunious girls a fee of five guineas for the examination which, if they pass, will enable them to be registered. I suppose this fee is to pay the expenses of the examination and the fees of the examiners. It is an extravagant charge and, in my opinion, ought to leave a considerable balance in the hands of the examining body. If so, the council ought to state their object in extracting this surplus money from a hard-worked and underpaid body of women. Is there some project to raise a fund to erect a college of nursing for the accommodation and aggrandisement of this important council? If this be the case, the women who are paying these fees should have some voice in the matter.

Much to the amusement of the medical profession, the council has issued an astounding syllabus of the medical knowledge to be acquired by nurses. It is so extensive that only the most highly intelligent women will be able to acquire more than a smattering of each subject, with the result that the confusion between medical and nursing knowledge will be at a maximum. And, in order to acquire this hotch-potch of knowledge, these girls will have to attend numerous lectures and study during their hours of leisure, although physically fatigued by the nature of their work. Or else the time spent on lectures, &c., will have to be included as part of their day's work, at the expense of the much more valuable practical training. The standard of most of the girls entering the nursing profession is neither socially nor intellectually as high as in former days. In my experience the slight improvement during the last two years is falling off. Consequently these girls are even less likely to absorb the excessive book knowledge which is aimed at. Moreover, it is not knowledge of this sort which produces the most capable nurses. The best ward sisters and nurses are by no means always those who have shone in the examination room.

If this pseudo-scientific examination is conducted so as to maintain a fairly high standard, it means the rejection of a certain number of reasonably capable nurses, possibly 20–30 per cent. Surely, this will prevent girls taking up this profession: three years' training, hard physical and mental work, a minimum salary, and possible rejection at the end. On the other hand, if the standard adopted is that in vogue at the various hospitals, where few fail to reach the standard deemed necessary for practising as a nurse, I see no necessity for a five guinea examination, unless it is a measure for obtaining money from these impecunious girls for some such purpose as above suggested.

Let me propose to the General Nursing Council that this scheme be dropped. It is ridiculous. If they wish to create a more highly qualified type of nurse, let them introduce a voluntary examination and give a special certificate or a diploma of nursing, and allow the rest of the nurses to be examined as at present. This might result in the development of two grades of nurses, one of which would be able to demand and would deserve higher fees, while the other will supply the public with the kind of nurse it often wants. Does the council suppose that raising the standard to an unduly high level is going to provide the type of nurse who will be content to nurse trivial and chronic cases, although these form the bulk of the cases in general practice?

I am, Sir, yours faithfully,

EDMUND CAUTLEY.

Park-street, W., Feb. 1st, 1924.

MEMORIAL TO THE LATE PROF. ASHLEY CUMMINS.

To the Editor of THE LANCET.

SIR,—The many friends and former students of the late Dr. W. Ashley Cummins, professor of the practice of medicine at University College, Cork, will learn with a sense of the keenest satisfaction that a project of providing a permanent tribute to his memory has been initiated.

It is thought that no more fitting memorial could be chosen than the endowment of a bed in the Victoria Hospital, to which Dr. Cummins devoted so much of his professional life. Those who knew Dr. Cummins will realise instinctively that he himself would have wished no other tribute to his memory than that his name should be associated for all time with the beneficent work of the hospital in which he took a keen and life-long interest, and of which his father was one of the founders.

Graduates of University College, Cork, who were associates or pupils of the late Prof. Cummins, and other members of the profession who feel so disposed, are invited to coöperate and to send donations to one of the signatories of this letter.

We are, Sir, yours faithfully,

C. B. PEARSON,
1, Sidney-place, Cork.

MICHAEL CAGNEY,
13, St. Patrick's-place, Cork.

Jan. 29th, 1924.

A CORRECTION.

Re REVIEW OF "EMERGENCY OPERATIONS FOR GENERAL PRACTITIONERS."

To the Editor of THE LANCET.

SIR,—I shall be glad if you will allow me to correct a series of singularly unfortunate errors and inaccuracies which appeared in a so-called "review" in THE LANCET of Jan. 26th regarding a new book of mine, entitled "Emergency Operations for General Practitioners on Land and Sea." After perusal of the somewhat imposing array of these inaccuracies, as enumerated below, I think it will be clear to you and to your readers that no worth can be attached to such a review, and that in fairness to author and publisher alike there should be an open acknowledgment of these incorrect statements:—

1. *The title* is incompletely given. This should have read "Emergency Operations for General Practitioners on *Land and Sea*." The latter part was quite omitted.

2. *The size* of the book was not stated. This should have been given as demy 8vo.

3. The number of printed pages contained in the book was most incorrectly stated as 1065, whereas the actual number is xii. + 135.

4. No mention is made regarding one of the chief features of the book—viz., the illustrations, of which there are 67, all original.

5. *The price* of the book is unfortunately as well as incorrectly stated to be 15*s.* instead of 7*s.* 6*d.*

6. Your reviewer has made misleading statements when he says, "Instructions how to find the cæcum in an appendix operation, and where to look for a perforated gastric ulcer, have been omitted." Now no one objects to a fair criticism of a published work, but inaccurate statements call for comment and correction. Had your reviewer made more than a superficial scanning of my book he would have found that the information he declares "missing" appears on pp. 33–34, and 30 respectively.

7. Again, there is an observation regarding strangulated hernia, that certain diagnostic points are absent. Had he carefully perused the preface, he would have noted that it is clearly pointed out that "questions regarding diagnosis are not entered into nor considered in this small volume."

8. Another of your reviewer's inaccuracies appears regarding "Intra-abdominal hæmorrhage." Arrest

f hæmorrhage in general is dealt with on pp. 115–122, hilst hæmorrhage from gastric and duodenal ulcers ppears on pp. 29–30. The absence of *rare* operations beyond criticism, as such absences are alluded to in general way in the preface.

9. Another incorrect statement is contained in the marks regarding end-to-end anastomosis, where it is aid that "no account of the operation is given." erhaps your reviewer will note that gastro-intestinal nastomosing and intestinal suturing are not only escribed, but both are fully illustrated by actual hotographs of the procedure, the former on p. 27 nd the latter on p. 75.

Bearing in mind, therefore, the complete series of istakes and incorrect statements as above shown, will be fairly obvious that the very dogmatic umming up of the book in question, as is contained in he closing sentence of this review, is as unjust as it is nmerited, and likely to ruin the sale of the book, ith consequent loss both to myself and to my ublishers.—I am, Sir, yours faithfully,

Newcastle-on-Tyne, Feb. 2nd, 1924. H. C. ORRIN.

*** We regret that in a review of "Emergency perations for General Practitioners on Land and ea, An Illustrated Manual of Procedure and Techique," by Mr. H. C. Orrin, surgeon to the Ministry of ensions Orthopædic Hospital, Newcastle-on-Tyne, he number of pages and price of the book were stated rongly through confusion with another volume. Ve have been unable to find in the book a statement f the price. The book contains 135 pages, including ndex, and is published at 7*s.* 6*d.*, the advertisement hich appeared in our issue of Jan. 19th being orrect. The book was reviewed under the title Emergency Operations for General Practitioners," he style which appears on the cover. We have rronged Mr. Orrin, and are happy to say so and to ublish his letter. This arrived when THE LANCET as at press, so that no opportunity arose to invite he reviewer to withdraw any statements, or opinions, r to qualify them in this issue. But inspection of the ook makes it clear that we are dealing here with ifferences of opinion and interpretation of words ather than with facts. A suggestion which reaches us. ot from Mr. Orrin, must be mentioned to be repudited. It is that the reviewer has taken cowardly dvantage of anonymity. Reviews in THE LANCET re not signed, and the charge of dishonesty must be net by ourselves with a denial.—ED. L.

INSTITUTIONAL MEDICAL OFFICERS AND INCOME-TAX ASSESSMENT.

To the Editor of THE LANCET.

SIR,—The Medical Defence Union has recently btained from the Special Commissioners of Income ax a decision which the Council of the Union feels s of such importance as to merit publication in the nedical press.

A member of the Medical Defence Union, who was he medical superintendent of one of the Metroolitan Asylums Board's Hospitals, by virtue of his ffice occupied a separate house in the grounds of he hospital rent free. The local inspector of taxes ought to assess our member upon the rateable alue of this house, treating it as an emolument of is office. The Union was accordingly consulted in he matter, and an appeal was lodged against this ssessment with the Special Commissioners. The ecision of the Commissioners has now been obtained, o the effect that the beneficiary occupation of a ouse in circumstances such as these is not an emolument within the meaning of the Finance Acts, and he assessment has therefore been discharged.

As there must be many medical men similarly laced, it is felt that the decision thus obtained ught to be made known in their interests.

I am, Sir, yours faithfully,

JAMES NEAL,
General Secretary, Medical Defence Union,
49, Bedford-square, London, W.C. 1, Feb. 5th, 1924.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

C. Godfrey to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

The undermentioned retire on ret. pay.

Majs. Robert J. Cahill (granted the rank of Lt.-Col.) and E. C. Whitehead.

The undermentioned Lts. are confirmed in their rank: W. B. F. Orr, F. J. O'Meara, and T. W. Davidson.

ARMY DENTAL CORPS.

Capt. J. C. Wood, late Spec. List., to be Capt.

INDIAN MEDICAL SERVICE.

Lt.-Col. R. A. Needham to be Brevet Colonel.

The King has approved the retirement of Lt.-Cols. P. St. C. More and E. M. Illington.

Mohan Singh Segat, Rajindar Singh Sandhu, and Achanvittil Krishna Menon to be Temp. Lts.

Lt.-Col. G. Tate's tenure of office as an elected member of the Punjab Medical Council expires on Feb. 24th, and the election of his successor is at present under consideration. Col. R. Heard, Inspector-General of Civil Hospitals, and Lt.-Col. W. C. H. Foster, Director of Public Health, have been appointed Members of the Punjab Legislative Council. Maj.-Gen. Benjamin H. Dare has been appointed a member of the Bengal Legislative Council. Col. Hugh Ainsworth has been appointed a Member of the Bihar and Orissa Legislative Council. Lt.-Col. H. G. Hutchinson has been granted eight months' leave.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary Comitia of the College was held on Jan. 31st, the chair being taken by Sir Humphry D. Rolleston, the President.—The following candidates were admitted to the Membership of the College: Drs. C. W. C. Bain, J. Bamforth, V. J. Bonavia, A. J. Cronin, B. Day, R. Hale-White, C. G. Imrie, J. H. Kelly, D. Pottinger, B. H. Spilsbury, A. Stokes, H. M. Turnbull, C. H. Whittle, and B. B. Yodh.—Licences to practise physic were granted to 198 candidates (including 32 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates:—

Robert D. Alexander, Cambridge and St. Thomas's; Cyril F. Ashby, St. Bart.'s; Joseph Atkin, Guy's; Naguib Fauzi Azer, Cairo and Charing Cross; Robert C. Baxter, Charing Cross; Harold P. Baylis, Guy's; John Bee, London; Edgar R. Bennion, Westminster; *Muriel E. Binns, Royal Free; Charles E. W. Bower, Manchester; Michael Angelo Boneventure Brito-Mutunayagam, Ceylon and St. Thomas's; William Brockbank, Cambridge and Manchester; Ronald W. Brookfield, Liverpool; Walter G. S. Brown, Cambridge and St. Bart.'s; Richard E. D. Cargill, Oxford and St. Bart.'s; Herbert D. Chalke, Cardiff and St. Bart.'s; James H. H. Chataway, Manitoba and St. Bart.'s; *Nora Cheney, King's College; Richard Chester, Leeds; William Clark, Charing Cross; George D. Clarke, Hyderabad and London; Robert G. Cochrane, Glasgow and St. Bart.'s; Thomas S. Cochrane, St. Bart.'s; Peter S. Conman, King's Coll.; Alexander M. Cooke, Oxford and St. Thomas's; *Rosemary Cooke, Cambridge and Charing Cross; Samuel S. Cruden, St. Bart.'s; Desmond E. Cuffey, Cambridge and King's Coll.; Edward R. Cullinan, St. Bart.'s; *Vera Cullwick, Birmingham; Charles H. C. Dalton, Cambridge and St. Bart.'s; Alfred F. D. Darlington, Cambridge and St. Thomas's; Arthur B. Davies, Guy's; John H. T. Davies and Phillip O. Davies, Cambridge and St. Bart.'s; Trevor Davies, St. Bart.'s; *Dorothy L. C. Day, London; Arthur M. Deane, St. Thomas's; John S. Dees, Bombay and Middlesex; Alexander de Souza, Cambridge and Middlesex; *Miriam P. de Villiers, Cape and Royal Free; George P. Driver, Manchester and St. Bart.'s; Wilfrid H. Dunn, St. Thomas's; *Winifred P. Edmunds, King's Coll.; *Barbara J. Edwards, Birmingham; John Elgood and Gilbert Elliot, St. Bart.'s; Vernon H. Ellis, London; Alfred C. M. Elman and Edwin S. Etheridge, Univ. Coll.; Daniel M. B. Evans, Cardiff and Charing Cross; Thomas J. Evans, Cardiff and Middlesex; Edward K. A. Firth, Edinburgh and St. Thomas's; Hubert H. Fisher, St. Bart.'s; Theodore F. Fox, Cambridge and London; Edgar S. Frischmann, Manchester; Maurice W. M. Gadrat, Paris; Philip Garson, St. Bart.'s; William H. George, Cardiff and London; Herbert M. Golding, Bristol; Horace P. Goldsmith, Univ. Coll.;

Wilfrid Gough and Frank E. Gould, Birmingham; Arthur W. Grace, Univ. Coll.; Hellmuth Graf, Liverpool; Francis H. K. Green, St. Bart.'s; Charles W. Greenway, Guy's; Robert J. Gregory, St. George's; Walter E. Grice, Middlesex; Arthur B. Griffiths, Liverpool; Griffith J. Griffiths, Middlesex; Reginald D. Gross, Guy's; Stanley A. Gunter, St. Bart.'s; John A. E. M. Hadley and Leslie W. Hale, Univ. Coll.; Charles S. Hallpike, Guy's; John G. Hamilton, London; Ivor E. Harries, Guy's; Kenneth E. Harris, Cambridge and Univ. Coll.; Arnold W. Hart-Perry St. Bart.'s; Rowland C. Hatcher, Bristol; *Leila M. Hawksley, Royal Free; Linley I. Henzell, Univ. Coll.; James C. W. Hewetson, Guy's; Ernest W. Hicks, St. Thomas's; Henry A. Hirst, London; James A. Hislop, Durham; Stanley A. Holford, Middlesex; John Holmes, Cambridge and St. Bart.'s; Arnold Hooper, Leeds; *Gwynedd Hugh-Jones and *Kathleen M. Hyslop, Royal Free; *Ethel J. Isaacs, Westminster; Harry Jaffe, Manchester; Thomas G. I. James, Cardiff; John W. W. Jepps, Cambridge and St. George's; Alan T. Jones, Cardiff and Univ. Coll.; William Jones, Univ. Coll.; Patrick C. Joscelyne, Bristol; Abdelaziz Abul Khair, St. Bart.'s; Edgar F. King, Bristol; Stanley W. M. King, Sydney and St. Bart.'s; *Charlotte A. Kingdon, Royal Free and St. Mary's; Frank Langford, Bristol; Arthur L. Lankester, Cambridge and St. Thomas's; Noel E. Laurence, St. Bart.'s; David E. Lawrence, Cardiff and St. Bart.'s; Harold B. L. Levy, Durham; *Geraldine N. Longford, St. Mary's; Gordon Lucas, London; *Kathleen M. Lyons, Univ. Coll.; Robert R. Macintosh and Norman W. MacKeith, Guy's; John R. A. Madgwick, London; *Doris I. Mart, Univ. Coll.; *Lucy M. T. Masterman, Royal Free and St. Mary's; Mendel Meyers, Cape and St. Bart.'s; Henry S. Morley, Univ. Coll.; Samuel W. H. Moul, Calcutta and Charing Cross; Raymond T. Mummery, Cambridge and St. Mary's; Carriappa Appayya Nadicarianda, Bombay and London; Bhagwant Singh Nat, St. Andrews; Eric E. Neser, Cape and Guy's; John W. Newbold, Bombay and Univ. Coll.; Isaac Newton, Charing Cross; Charles P. O'Brien, Bombay and St. Bart.'s; Frederick W. Oldershaw, London; Robert D. Owen, Cardiff and Guy's; Robert Owen-Jones, Middlesex; *Lucy Parker, Royal Free; Griffith W. V. Parry, Cardiff and Guy's; Thomas G. W. Parry and William F. Payne, Guy's; Philip R. Peacock, Middlesex; *Betsey Porter, Liverpool and Royal Free; *Louisa M. Poynder, Bombay and Charing Cross; Trevor M. Preece, Cambridge and St. Bart.'s; Eric A. B. Pritchard, Cambridge and Univ. Coll.; *Evelyn R. Pyke and Alfred J. Reed, London; *Laura M. Rhodes, Royal Free and St. Mary's; Richard L. Rhodes, Cambridge and St. Bart.'s; Oliver F. W. Robinson, Belfast and King's Coll.; Morris Rockfelt, Univ. Coll.; Ernest J. H. Roth, St. Bart.'s; Stanley C. Rowbotham and Max Rubinstein, Guy's; Edgar Rudge, Cambridge and St. Bart.'s; Robert W. Savage, St. Bart.'s; *Margaret B. Savory, Univ. Coll.; Robert W. Scarff, Middlesex; Francis L. Scott, King's Coll.; Eric C. Seward, Guy's; Christopher J. L. Sharp, Cambridge and London; Hubert Sheard, Leeds; Julius Silver, Middlesex; Francis A. H. Simmonds, Cambridge and St. Bart.'s; Alan S. Simpson and Arthur E. Slinger, King's Coll.; Gerald F. Smith, Middlesex; Nathan Smith, Cape and St. Bart.'s; James A. Smorfitt, Leeds; *Beatrice M. Smyth, Cambridge and London; Samuel Snelson, Manchester; Walter R. Spurrell, Guy's; Reginald H. Stanbridge, London; Richard S. Starkey, Cambridge and St. Thomas's; Eric G. Steeler, St. George's; William Stephenson, Durham; Joseph D. M. Stewart, Cambridge and St. Bart.'s; *Viva Eileen K. Stuart, Royal Free and St. Mary's; *Edith C. Summerskill, Charing Cross; Harish Chandar Suri, London; Hugh H. D. Sutherland, St. Bart.'s; Thomas R. Sutherland, Cambridge and St. Bart.'s; *Annie D. Symons, Royal Free; Alan K. Thomas, Univ. Coll.; William E. C. Thomas, Cardiff; Kenneth W. Thorp, Cambridge and St. Thomas's; Robert W. H. Tincker, St. Bart.'s; Horace S. Townsend, King's Coll.; Bernard D. Underwood, London; Hubert C. Van Dort, Ceylon and Middlesex; Douglas C. Vaughan, Manchester; Harold F. Walker, Middlesex; Sidney A. Walker, Liverpool; *Dorothy A. Waterfield, London; Edmund R. Weaver-Adams, Cambridge and St. Thomas's; *Elizabeth N. Wells, Charing Cross; Henry J. W. J. Westlake, Guy's; Henry A. M. Whitby and Harold B. White, St. Bart.'s; *Fanny M. Whittaker, Charing Cross; George William Wigg, Durham; *Cicely F. Wilson, Bristol; Albert W. Wood, Birmingham; *Constance A. P. Wood, King's Coll.; and Stanley C. H. Worseldine, Guy's.

* Under the Medical Act, 1876.

Diplomas in the undermentioned subjects were granted, jointly with the Royal College of Surgeons of England, to the following candidates:—

DIPLOMA IN PUBLIC HEALTH.

Ephraim Benjamin, Bombay and King's Coll.; Florence Bentham, St. Mary's and King's Coll.; Mohan Lal Bery, Manchester; Frederick J. Darbyshire, Westminster and Roy. Inst. Public Health; May C. Ferguson, N.U.I. Dublin and Roy. Inst. Public Health; Jitendra Mohan Ghosh, Calcutta and Univ. Coll.; Madhao Ramrao Goverdhan, Bombay and Roy. Inst. Public Health; Eleanor Harse, Royal Free and Univ. Coll.; Ernest C. Holtom, R.N. Haslar and Univ. Coll.; Ivor Lewis, Univ. Coll.; Reginald C. Lightwood, King's Coll.; William S. McGillivray, Aberdeen and Univ. Coll.; Robert H. Parry, Middlesex; Hubert C. G. Pedler, Univ. Coll.; Mangalam Kesavavaliathan Gopala Pillai, London and Roy. Inst. Public Health; Ruth W. Plimsoll, Royal Free, St. Mary's, and Univ. Coll.; John Reid, Cork and Roy. Inst. Public Health; Percy M. Rivaz, Durham and Roy. Inst. Public Health; Campbell Ross, Glasgow; Effie F. A. Samter, Manchester and Univ. Coll.; Narinjan Singh Sethi, Punjab and Univ. Coll.; Robert W. G. Stewart, Belfast and Naval Med. School, Greenwich; Maurice L. Sutcliffe, Univ. Coll.; Ian S. Thomson, Aberdeen and Roy. Inst. Public Health; Joseph R. Tibbles, Aberdeen, Univ. Coll., and London; Joseph Whitby, Middlesex and Roy. Inst. Public Health; and Samuel A. Withers, Univ. Coll.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.

Yousif Abul-Nasr Barrada, Cairo; Phanindra Nath Basu, Calcutta; Madan Gopal Bhandari, Punjab; Hari Das, Univ. Coll.; William K. Dunscombe, Durham; Arthur A. Hearne, Aberdeen; Harrie B. Lee, Melbourne; George R. McRobert, Aberdeen; Percy S. Mills, Guy's; William L. Paterson, Glasgow; Percy S. Selwyn-Clarke, St. Bart.'s; Tinnevelly Subbiar Tirumurti, Madras; Hyla S. Watters, Cornell; Clifford L. Wilmoth, Chicago; and Arthur D. Wright, St. Mary's. (All the above were students at the London School of Tropical Medicine.)

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Douglas R. Alexander, St. Mary's and Bexley; Francis G. L. Barnes, St. Bart.'s and Colney Hatch; James D. Dyson, Middlesex and Maudsley; Alan F. Grimbly, Dublin and Colchester; Henry D. Hayes, Edinburgh and Bexley; William J. Lascelles, Belfast and Hanwell; Douglas B. M. Lothian, Edinburgh and Banstead; Ernest E. Pittman, Sydney and Bethlem; and Jyotirmay Roy, Calcutta and Bethlem.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.

William E. Jennings, Edinburgh and Ind. Med. Service; Alexander E. MacDonald, Toronto and Roy. London Ophth. Hosp.; Reginald V. Martin, St. Mary's and Roy. London Ophth. Hosp.; Wazir Chand Mathur, Punjab and Roy. London Ophth. Hosp.; John K. Raymond, Edinburgh and Roy. London Ophth. Hosp.; Archibald A. B. Scott, St. Andrews and Roy. West. Ophth. Hosp.; Tarachand Dayasing Shahani, Bombay, Oxford, and Roy. London Ophth. Hosp.; Philip L. Stallard, St. Thomas's, Oxford, and Royal London Ophth. Hosp.; Lance H. Stanton-Cook, Sydney and Roy. London Ophth. Hosp.; Evan K. R. Thomas, Edinburgh and Birmingham and Mid. Eye Hosp.; Victor G. Walker, Trin. Coll., Dublin, and Roy. London Ophth. Hosp.; and Gladys M. R. Webster, Roy. Free and Cent. London Ophth. Hosp.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.

James B. Horgan, Cork and Golden Square; and William Wilson, Belfast and King's Coll. Hosp.

Sir Charles Sherrington was elected councillor for one year, vice Dr. Buzzard, now Censor. Drs. Drysdale, Poynton, Abram, and T. Wardrop Griffith were also elected councillors in place of Drs. Beddard, A. J. Hall, J. W. Russell, and Gowland Hopkins, who retire by rotation.—Sir Dyce Duckworth was reappointed representative of the Court of Governors of the University of Liverpool; Dr. Voelcker was reappointed on the Court of Governors of the University of Birmingham. Sir William Hale-White was reappointed representative on the Central Council for District Nursing in London. Sir Francis Champneys was appointed representative on the Central Midwives Board.—The President announced that the Council had appointed Dr. A. S. MacNalty to be Milroy Lecturer in 1925.—A proposed lecture on angina pectoris by Prof. Wenckebach, of Vienna, was approved.—A letter was read from Dr. J. A. Hayward, asking that the membership may be restored to him.—The Senior Censor gave notice that at a future meeting of the College he will move "That by-law 194 be amended so as to make women eligible for the Fellowship."—Reports were received from the Committee of Management as follows, and the recommendations made in them were adopted.

The Committee of Management recommend: (1) Addition of the East Suffolk and Ipswich Hospital to the list of hospitals recognised by the Examining Board in England: (2) addition of the Detroit College of Medicine and Surgery, Detroit, Michigan, U.S.A., to the list of institutions whose graduates in medicine are admissible to the Final Examination of the Examining Board in England under the conditions of Paragraph IV., Section III., of the Regulations.

The Committee had considered an application from a Diplomate in Public Health of the Royal Colleges for a certificate that he had obtained the diploma, his original diploma having been lost. There is no authority at present for issuing a certificate of a diploma granted jointly by the two Royal Colleges; in view of the number of such diplomas, the Committee think it desirable to make provision for issuing a certificate of a diploma; the Committee of Management therefore recommended that on receipt of a statutory declaration made by the applicant, setting forth the manner and date of the loss of the diploma, the secretary of the Conjoint Examining Board in England be authorised to issue a certificate stating that the diploma had been granted to the applicant and the date on which it was issued.

The Committee of Management had recently received applications for admission to the Final Examination from graduates of medicine of Russian universities, under the conditions of Paragraph IV., Section III., of the Regulations. In cases where the course of study and the examinations were completed before the year 1916 these applications were

granted. As the Committee are not satisfied that, under present conditions, the standard of medical education and examination on which the Russian universities were formerly recognised, is maintained, they recommended the Royal Colleges to remove the Russian universities from the list of institutions recognised by the Examining Board in England. The Committee recommended that the College of Medical Evangelists, Loma Linda, California, U.S.A., be added to the list of institutions whose graduates in medicine are admissible to the Final Examination of the Examining Board in England under the conditions of Paragraph III., Section III., of the Regulations.

After reports of some Committees had been received, and other formal College business transacted, the President dissolved the Comitia.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates have passed the Triple Qualification Examination :—

FINAL EXAMINATION.

Matthew Burn, Charles A. Murray, Leonard A. Watson, Richard F. Kerr, Alexander J. M. Findlater, Jitendranath Dey, Oswald L. Shearer, Donald Jack, Claude A. Parry, Wilhelmina Cochrane Storrie, Patel Shankerlal Hathibhai Masters, Akinlawon Adefolu, Hariprasanna Sen, David K. Fisher, Arnold Raff, Arthur W. H. Noble, Elizabeth Clark, Raymond L. A. Kitchen, Ivo E. Meier, Jacob S. Liptz, Isaac Goldberg, Joseph McAuley, William Melrose, and Clement A. Barrow.

Medicine.—William D. Howat, Annie H. Sutherland, John C. Colvin, Harry Myers, Matthew Clouts, Morris Kelman, Alexander S. Ballantine, Sam Noll, Sudhindra Nath Bandyapadhay, Israel Rostowsky, James Courtney, James H. MacAlpine, and Robert D. Scorgie.

Surgery.—Oliver H. D. Oliver, Frederick W. Robinson, Patrick Murray, James H. MacAlpine, and John Paterson.

Midwifery.—Joseph F. Sweeney, William D. Howat, John C. Colvin, Douglas D. O. McLoughlin, Harry Myers, Matthew Clouts, Morris Kelman, Sam Noll, and Robert D. Scorgie.

Medical Jurisprudence.—Robert H. McKinnon, John J. McKenna, Trevor Hughes, Petrus Johannes Badenhorst, David D. H. Craig, Eleanor P. Topping, Isaac Joels, Daniel T. Gemmell, John J. MacKenzie, Matthew L. Hendrie, Lewis Mackenzie, David S. Middleton, and Adam S. Gordon.

UNIVERSITY OF LONDON.—A meeting of the Senate was held on Jan. 30th, the Vice-Chancellor, Mr. H. J. Waring, being in the chair. The following appointments were made :—Sir Sydney Russell-Wells, M.P., member of the General Medical Council ; Dr. R. A. Lyster, representative at the thirty-fifth congress of the Royal Sanitary Institute to be held at Liverpool in July next ; Prof. H. R. Kenwood, representative (in respect of University College) at the above Congress.

A course of seven free public lectures on the current work of the Biometric and Eugenics Laboratories will be held at University College, Gower-street, W.C., on Wednesdays at 6 P.M., from Feb. 13th to March 26th inclusive. Among the subjects dealt with will be the "Biometric Study of Cancer," by Dr. M. Greenwood ; "Inheritance in Finger Prints and the Possibility of their Use in Cases of Disputed Paternity," by Miss Ethel M. Elderton ; and the "Contributions of Sir Francis Galton to Photography," by Prof. Karl Pearson.

TUBERCULOSIS SOCIETY.—An ordinary meeting of this Society will be held at the Margaret-street Hospital, Margaret-street, W., on Friday, Feb. 15th, at 8 P.M., when Dr. Clive Riviere will read a paper on Artificial Pneumothorax as I See it To-day. The annual provincial meeting of the Society will be held at Cambridge on Thursday, Friday, and Saturday, April 10th, 11th, and 12th.

HARVEIAN SOCIETY OF LONDON.—At the annual meeting of this Society, held on Jan. 16th at 11, Chandos-street, the following were elected officers of the Society for the year 1924 :—President : Dr. Reginald Dudfield. Vice-Presidents : Mr. D. C. L. Fitzwilliams, Dr. Montague Smith, Dr. W. E. Falconar, and Dr. C. M. Wilson. Treasurer : Dr. G. de Bec Turtle. Hon. Secretaries : Dr. Alfred Hope-Gosse and Dr. W. G. Bendle. Council : Dr. Edwin Ash, Mr. Gordon Bryan, Dr. Charles Buttar, Sir Crisp English, Mr. G. A. Ewart, Dr. W. Jagger, Dr. A. Langwill, Mr. C. A. Pannett, Dr. K. Playfair, Dr. E. F. Pratt, Dr. Herbert Tanner, and Dr. O. S. Thompson.

CONFERENCE ON MARITIME QUARANTINE.—Dr. Belisario Porras, President of the Republic of Panama, has called a conference to meet in Panama from Feb. 25th–29th to consider the international standardisation of maritime quarantine on the west coast of South America and the prevention of international spread of communicable disease along that littoral. The Secretary-General of the conference is Surgeon William Colby Rucker, U.S. P.H.S., Chief Quarantine Officer of the Canal.

The Right Hon. John Wheatley, M.P., Minister of Health, has appointed Dr. L. Haden Guest, M.P., to be his Parliamentary Private Secretary (unpaid).

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At a meeting to be held at the Miller General Hospital, Greenwich, to-night (Friday), at 8.45 P.M., Dr. E. G. Annis in the chair, a paper on Experimental Work on the Internal Secretion of the Testis, and Rejuvenation Operations will be read by Mr. Kenneth M. Walker.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next quarterly meeting of the Association will take place on Thursday, Feb. 21st, at 11, Chandos-street, Cavendish-square, W.1, under the presidency of Lieut.-Col. E. Goodall, M.D., at 2.45 P.M., when a paper entitled Twenty-eight Years' Lunacy Experience in Egypt will be read by Dr. John Warnock.

ASSOCIATION FOR THE PREVENTION AND RELIEF OF HEART DISEASE, NEW YORK.—At the annual meeting held in January the following Board of Governors was elected for a term of five years :—Dr. Nathan E. Brill, Dr. Lewis A. Conner, Dr. B. S. Oppenheimer, Mr. Vernon Munroe, and Mrs. A. F. Tiffany. The Governors proceeded to elect the following officers for the coming year :—Dr. Haven Emerson, President ; Dr. Robert H. Halsey, Vice-President ; Dr. William St. Lawrence, Secretary ; and Mr. Edwin O. Holter, Treasurer.

THE BRITISH ASSOCIATION : ANNUAL MEETING IN TORONTO.—The preliminary programme of the annual meeting of the British Association in 1924, to be held in Toronto, Ontario, on August 6th to 13th, under the presidency of Sir David Bruce, has just been issued. The Association will meet in 13 sections. In the section of anthropology, Mr. E. N. Fallaize, Vinchelez, Chase Court-gardens, Enfield, Middlesex, is recorder ; for physiology, Prof. C. Lovatt Evans, Physiological Laboratory, St. Bartholomew's Medical College, London, E.C. 1 ; and for psychology, Dr. Ll. Wynn Jones, 7, St. Mary's-avenue, Harrogate. The inaugural general meeting will be held on Wednesday, August 6th, in the Convocation Hall of the University.

THE LATE DR. A. H. COOK.—Dr. Augustus Henry Cook, who died at his residence at Hampstead on Feb. 1st, was the son of William Henry Cook, M.D., of Edinburgh. He was born in 1857, and was educated at Highgate Grammar School. After studying medicine at University College, London, he qualified L.S.A. and M.R.C.S. Eng. in 1881, obtained the L.R.C.P. Lond. the following year, and gained the M.B. Lond. in 1885. He became senior surgeon and senior anæsthetist to the Hampstead General Hospital, with which his association dated almost from its foundation. He held appointments as anæsthetist to the Hampstead Military Hospital, and as surgeon to the Rosslyn Lodge Auxiliary Military Hospital. He was medical officer to the Infants' Hospital, Hampstead, and clinical assistant in the Soho-square Women's Hospital. Dr. Cook was the author of four volumes of poetry—"The Sirens," "Rizpah," "Psyche," and "Eve Repentant." His contributions to medical literature included articles on typhus complicated with ulcerative endocarditis and cerebro-spinal fever due to pneumococcus.

MANCHESTER ROYAL INFIRMARY.—The report for 1923 states that the annual subscriptions show a substantial increase since 1922, and though through trade depression £584 of subscriptions had been withheld, there was to be set against this temporary loss a net permanent gain of £1618 in view of increased subscriptions. Donations were not up to the 1922 level, but patients' contributions were better than in previous year. The ordinary income of the infirmary and the Barnes Convalescent Home was £85,539, and the total ordinary expenditure was £108,894. The sum of £500 was spent on insulin, "from which markedly beneficial results had been obtained."

MOORFIELDS X RAY DEPARTMENT.—An appeal is being made by the Moorfields Eye Hospital for the sum of £700 to equip the X ray department with modern apparatus. At present the only apparatus in the X ray department which is in good condition is that invented by the late Sir James Mackenzie Davidson for localising foreign bodies in the eye. The committee consider the occasion is specially appropriate for commemorating the valuable services rendered to the hospital by Sir James Mackenzie Davidson, and in appealing for special donations for the X ray department they feel confident that the friends of the hospital will make a generous response. Contributions may be addressed to Secretary Superintendent, Moorfields Eye Hospital, City-road, E.C. 1.

THE LATE DR. T. B. SCOTT.—Dr. Thomas Bodley Scott, Mayor of Bournemouth, died on Feb. 2nd, aged 72. The son of a Brighton surgeon and a descendant of the founder of the Bodleian at Oxford, he received his early education at Brighton College, whence he proceeded to St. Bartholomew's Hospital to study medicine. Having graduated M.R.C.S. Eng. in 1874 and L.R.C.P. Edin. in the following year, he held an appointment for a time as house physician at St. Bartholomew's. About 1876 he took up general practice in Bournemouth, and soon won a position of esteem among his fellow townsmen. In 1921 he entered the borough council, and he died during his term of office as mayor. Dr. Scott latterly published several books of general as well as professional interest, such as "The Religion of a Doctor," "Why Do We Die?" "The Road to a Healthy Old Age," "Modern Medicine and Some Modern Remedies," and "Endocrine Therapeutics." He wrote with charm and with personal conviction, giving a message of hope for those past middle age who were beginning to feel the burden of the years. He was one of the first advocates in this country of the use of thyroid extract in threatening eclampsia, and of the value of anterior pituitary in high tension. In all his writings he brought to bear a wide and personal experience, so that the reader could feel he was on sure ground. Of his contributions to medical journals, an article on Vaccine Treatment appeared in THE LANCET, vol. ii., 1912.

With the death of Dr. Scott another living link with Robert Louis Stevenson has been snapped, for Dr. Scott was Stevenson's medical attendant and intimate friend between 1884 and 1887 when Stevenson was living in Bournemouth. When "Underwoods" was published it was dedicated to several of Stevenson's doctors, but especially to Dr. Scott. Of him Stevenson wrote: "But one name I have kept on purpose to the last because it is a household word with me, and because, if I had not received favours from so many hands and in so many quarters of the world, it should have stood alone—that of my friend, Thomas Bodley Scott, of Bournemouth." He married Adeline, daughter of Albert Savory, Potters Park, Chertsey, and had eight sons and two daughters.

VISITING ASSOCIATION OF THROAT AND EAR SURGEONS OF GREAT BRITAIN.—This Association has been formed in order to enable members of the specialty from different parts of the country to visit home and foreign clinics. It is intended to pay a short visit to a home clinic once a year, and another somewhat longer one to a foreign clinic. As the chief purpose is to study operative technique, the membership must necessarily be limited to a number who can watch an operation at one time in reasonable comfort. The first meeting of the Association was held in Edinburgh on Jan. 25th and 26th, when the morning of the first day was spent in watching the work in the throat clinic. Dr. J. S. Fraser performed two radical mastoid operations with skin grafting. Mr. J. D. Lithgow demonstrated the induction of fibrosis in the inferior turbinals by injection of carbolic in glycerine. Dr. W. T. Gardiner performed Sluder's ethmoidal operation, and Dr. G. Ewart Martin performed endoscopy, including aspiration and lavage of a bronchiectatic cavity. The afternoon was occupied in listening to the pathological demonstrations of Drs. A. Logan Turner and F. E. Reynolds (with lantern) on the intracranial complications of accessory sinus suppuration, and to Dr. Fraser on some points in the pathology of the inner ear. On the morning of the second day the members were able to watch Sir Harold Stiles, F.R.S., perform an operation of interest alike to the general and to the throat surgeon. He first operated upon a pharyngeal pouch, which by its smallness rendered the operation more difficult; he then removed from the neck a very large mass of tuberculous cervical glands in which abscess formation had occurred. After this a clinical demonstration was given by Dr. Douglas Guthrie, at the Royal Hospital for Sick Children. Sir William Milligan is president of the Association, the joint hon. secretaries being Mr. T. B. Layton, 10, Welbeck-street, London, W. 1, and Mr. Musgrave Woodman, 22, Newhall-street, Birmingham.

DONATIONS AND BEQUESTS.—The Royal Manchester Children's Hospital during the past month received subscriptions and donations amounting to £6521, including donations from His Majesty the King, part profits on the sale of Their Majesties' "Empire Day Message," the Lord Mayor of Manchester's Two Million Shilling Fund, £5000; Booth Charities, £250; Dickenson Charity, £150.—Hon. Louisa Henrietta Rennell, of Eaton-place, S.W., left £500 each to the Hospital for Consumption, Brompton, and the Hospital for Incurables, Putney; £1000 each to the Hospital for Seamen, Greenwich, and the British Hospital for Mothers and Babies, Woolwich; and £100 to the Earlswood Asylum for Idiots.—Mr. Alfred Charles Latter, of Sevenoaks, Kent, left £500 to the Eltham and Mottingham Cottage Hospital.—Miss Dora Twyford, of Whitmore Hall, Staffordshire, left £12,000 to the North Staffordshire Infirmary for the erection of a permanent annexe in memory of her father and mother, and £1000 for the general funds of the infirmary. She also left £12,000 to the Hanley Infants Welfare Society.—Mr. John B. Don, of Maulesden, has given £500 to the Forfar Infirmary towards the cost of a new surgical table and X ray apparatus.—By the will of the late Mr. Lewis Midgley, of Harrogate and Manchester, the testator left among other bequests £652 10s. to the Bradford Infirmary; £100 to the Bradford and District Nursing Association; £200 to the Harrogate Infirmary; and £500 to the Manchester Royal Infirmary.—The late Mr. David Politi, of Stoke Newington, N., left by will £500 to the Metropolitan Hospital for endowing a bed in the names of his late wife and himself; £100 to the Children's Hospital, Hackney; £100 to the Jewish Home for Incurables at Tottenham; and £100 to the Jewish Hospital, London.

MEMORIAL TO SIR FRANCIS FARMER.—The death of Sir Francis Farmer, the well-known dental surgeon, on Dec. 24th, 1922, was followed by letters in the press, in which a hope was expressed that a memorial to him and his work would be dedicated at the London Hospital. In November last a few friends decided to circularise by letter a number of those who were known to have been acquainted with Sir Francis Farmer. The letter stated that the proposed memorial was to be partly in the form of a mural tablet in the Dental School of the London Hospital, and partly in the form of an endowment of a scholarship or prize to be associated with his name. There was a wide response to the letter, but there are, no doubt, others, with whom the committee have been unable to communicate, who would like to be associated with the memorial. The committee wish it to be known that the fund is still open, and that subscriptions may be sent to either of the hon. treasurers, Mrs. M. L. Hodges, The Woodlands, Isleworth, or to Sir Herbert Ellissen, 24, Ulster-place, Regent's Park, N.W. 1.

POST-GRADUATE STUDY IN BONN.—A post-graduate course in X ray therapy and X ray diagnosis will take place at Bonn, Rhineland, Germany, from Feb. 24th to March 1st. The lectures will be under the following headings: (1) X ray burns and how to prevent them, by Prof. P. Krause; (2) X ray therapy in gynæcology, by Prof. O. von Franque and Prof. H. Martius; (3) X ray therapy in skin diseases, by Prof. E. Hoffmann and Dr. Schreus; (4) The physics of X rays, by Prof. L. Grebe; (5) The effect of X rays on plants, by Prof. M. Koernicke; (6) The changes produced by therapeutic irradiations from the point of view of the anatomical pathologist, by Prof. Prym; (7) X ray diagnosis in surgery, by Dr. Naegeli; (8) X ray therapy and diagnosis of internal diseases, by Dr. Kading. Medical men who wish to take part in this course of lectures should apply to Prof. Martius, Universitäts-Frauenklinik, Theaterstrasse 5. A registration fee of 5 gold marks is charged to cover the running expenses.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Feb. 11th.

WAR: at 5 P.M.
Paper:
Surg.-Comdr. R. J. G. Parnell, R.N.: Bismuth in the Treatment of Syphilis.
To be followed by a discussion.

Tuesday, Feb. 12th.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 P.M.
Papers:
Mr. J. B. S. Haldane: Experimental and Therapeutic Alterations of Human Tissue Akalinity.
Dr. E. P. Poulton: Anuria in Hypoglycæmic Coma.
PSYCHIATRY: at 8.30 P.M.
Paper:
Dr. Crichton Miller: The Physical Basis of Emotional Disorder.

Wednesday, Feb. 13th.

SURGERY: SUB-SECTION OF PROCTOLOGY: at 5.30 P.M.
Cases and Specimens will be shown by Sir Charles Gordon-Watson, Mr. Gabriel, Mr. Graeme Anderson, and others.

Thursday, Feb. 14th.

NEUROLOGY: at 8.30 P.M.
Paper:
Dr. C. P. Symonds: Spontaneous Subarachnoid Hæmorrhage.

Friday, Feb. 15th.

ELECTRO-THERAPEUTICS: at 8.30 P.M.
Paper:
Dr. E. W. Twining and Dr. R. Williamson: Gas Replacement in the Treatment of Pleural Effusions.

ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle-street, W. 1.
TUESDAY, Feb. 12th.—5.15 P.M., Joseph Barcroft, F.R.S.: The Respiratory Pigments in Animal Life and Their Significance (Lecture I.).

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Feb. 11th.—8.30 P.M., Discussion on the General Symptoms and Remote Manifestations of Common Affections of the Naso-pharynx, Accessory Sinuses, and Throat. To be introduced by Mr. Herbert Tilley, followed by Lord Dawson, Dr. John Poynton, Mr. W. M. Mollison, Dr. E. M. Callender, Sir Thomas Horder, Mr. C. W. M. Hope, Mr. E. D. D. Davis, and others.

CUNTERIAN SOCIETY.
TUESDAY, Feb. 12th.—Annual Dinner at the Langham Hotel.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
MONDAY, Feb. 11th.—5 P.M., Prof. W. Sampson Handley: General Peritonitis.
WEDNESDAY.—5 P.M., Prof. R. Lawford Knaggs: Osteogenesis Imperfecta.
FRIDAY.—5 P.M., Mr. V. E. Negus: The Mechanism of the Larynx.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W. 1.
MONDAY, Feb. 11th, to SATURDAY, Feb. 16th.—Combined Course on Diseases of Children. Clinical Demonstrations and Lectures from 10 A.M. to 4.30 P.M. daily, including the ROYAL WATERLOO HOSPITAL, VICTORIA HOSPITAL FOR CHILDREN, and PADDINGTON GREEN CHILDREN'S HOSPITAL.—CENTRAL LONDON OPHTHALMIC HOSPITAL. Clinical Lecture Demonstration every afternoon. Mon., 2 P.M., Mr. Oliver. Tues., 2.30 P.M., Mr. Gibb. Wed., 2.30 P.M., Mr. Levy. Thurs., 2.30 P.M., Mr. Cunningham. Fri., 4.30 P.M., Mr. Williamson-Noble (Pathological).—LONDON LOCK HOSPITALS. Clinical Work daily; Lectures at Dean-street. Mon., 5 P.M., Mr. Gibbs: Treatment of Syphilis. Tues., 2.30 P.M., Mr. McDonagh: The Theory and Practice of the Treatment of Syphilis. Wed., 5 P.M., Mr. Juler: Syphilitic Affections of the Fundus Oculi. Thurs., 2.30 P.M., Mr. Corbett: Practical Demonstration of Tests used in Syphilis and Gonorrhœa. Fri., 4 P.M., Mr. Johnston Abraham: Late Sequelæ of Gonorrhœa in the Female.—LONDON SCHOOL OF TROPICAL MEDICINE. Tues. and Thurs., 2 P.M., Special Clinical Demonstrations. NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital), Tottenham. Special Intensive Course (Second Week).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Feb. 11th.—10 A.M., Surgical Registrar: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 2.30 P.M., Mr. Addison: Surgical Wards.
TUESDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations and Wards. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Mr. Simson: Gynæcological Dept. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
FRIDAY.—10.30 A.M., Dr. Pritchard: Medical Wards. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Dept. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.
POST-GRADUATE COURSE: FEBRUARY–MARCH, 1924.
CLINICAL LECTURES AND DEMONSTRATIONS.
MONDAY, Feb. 11th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Epileptic Equivalents and Borderland Syndromes: Dr. Kinnier Wilson.
TUESDAY, Feb. 12th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Cranial Nerve Palsies: Dr. Risien Russell.
THURSDAY, Feb. 14th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Polyneuritis: Dr. Gordon Holmes.
FRIDAY, Feb. 15th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Recent Studies on the Vestibular Nerve: Mr. Sydney Scott.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.
MONDAY, Feb. 11th.—12 noon, Neurosyphilis. II.: Dr. J. G. Greenfield.
The Fee for the Course, including Pathology, is £5 5s. For those who hold Perpetual Tickets the fee is £3 3s.

COURSE OF LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.
WEDNESDAY, Feb. 13th.—12 noon, Development; Units of Structure and Function.
THURSDAY, Feb. 14th.—12 noon, Spinal Cord; Anatomy; Intrinsic and Extrinsic Systems: Dr. Kinnier Wilson.
The Fee for this Course will be £2 2s.
Dr. F. M. R. Walshe will give a COURSE OF EIGHT CLINICAL DEMONSTRATIONS, CHIEFLY ON METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, in the Wards at 10 A.M., every Wednesday and Thursday during February. The numbers attending the Course will be limited. Fee £2 2s.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE NEUROLOGY OF THE EYES.
WEDNESDAY, Feb. 13th.—3.30 P.M., Papilloedema and Optic Neuritis: Mr. Leslie Paton.
The Fee for this Course alone is £5 5s. If taken in conjunction with the general Post-Graduate Course the fee is £3 3s. All applications should be sent to the Secretary, Medical School.
Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday morning at 9 A.M., or at such other times as may be announced.
Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.
J. G. GREENFIELD, Dean of Medical School.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
TUESDAY, Feb. 12th.—5 P.M., Dr. Graham Little: Pityriasis Rosea.
THURSDAY.—5 P.M., Dr. J. L. Bunch: Tuberculosis.

UNIVERSITY COLLEGE, Gower-street, W.C.
FRIDAY, Feb. 15th.—5 P.M., Prof. J. Robertson: The Influence of Improved Town Planning and Housing in Public Health. (Last lecture.)

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Feb. 14th.—4 P.M., Mr. Doyne: Ophthalmia Neonatorum.

CANCER HOSPITAL, Kensington, S.W.
WEDNESDAY, Feb. 13th.—4.30 P.M., Dr. T. B. Vaile: Surgical Anæsthesia by Nitrous Oxide and Oxygen.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
THURSDAY, Feb. 14th.—5 P.M., Mr. L. C. Rivett: The Value of Ante-natal Examination.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)
MONDAY, Feb. 11th.—(At the Children's Hospital.) Dr. Fordyce: Clinical and Pathological.
TUESDAY.—(At the Southern Hospital.) Dr. de Courcy: The Use of the Ophthalmoscope in General Practice.
WEDNESDAY.—(At the Northern Hospital.) Dr. M. Bligh: Empyema in Adults and Children.
THURSDAY.—(At the Stanley Hospital.) Miss Nicholson: Gonorrhœa in the Female.
FRIDAY.—(At the Royal Infirmary.) Dr. Buchanan: Medical Cases.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
MONDAY, Feb. 11th.—4.15 P.M., Mr. S. R. Wilson: Recent Improvements in Anæsthesia.
TUESDAY.—4.15 P.M., Sir William Milligan: Present Position of Labyrinthine Surgery.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES.
THURSDAY, Feb. 14th.—4.30 P.M., Mr. A. C. Magian: The Gynæcological Causes of Married Unhappiness.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES.
TUESDAY, Feb. 12th.—(At the Royal Infirmary.) 3.30 P.M., Mr. Mouat: Common Disabilities of the Foot.
FRIDAY.—(At the Royal Hospital.) 3.30 P.M., Mr. Morrell: Radiology in the Diagnosis of Obscure Conditions. (Illustrated.)

SALFORD ROYAL HOSPITAL LECTURES.
THURSDAY, Feb. 14th.—4.30 P.M., Dr. H. T. Ashby: Rheumatism in Children.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Feb. 13th.—4 P.M., Dr. P. C. Varrier-Jones: Settlements for Tuberculosis.

Appointments.

FORRESTER, A. T. W., M.D. Lond., has been appointed Medical Superintendent of the Warwick County and County Borough of Coventry Mental Hospital.
GOMPERTZ, R. H. C., M.B., B.S. Lond., Medical Referee under the Workmen's Compensation Act for the County Courts of Barnstaple, &c.

MILLER, J. R., M.B., Ch.B. St. And., Resident Medical Officer, Dumfries Royal Infirmary.

O'SULLIVAN, P. T., M.D., B.Ch.R.U.I., Professor of Medicine, University College, Cork.

TODD, A. H., M.S., B.Sc. Lond., F.R.C.S. Eng., Consultant in Orthopædic Surgery for the Royal Air Force, and Assistant Surgeon, The Royal Hospital, Richmond.

Manchester Royal Infirmary: KLETZ, N., M.B., Ch.B. Manch., M.R.C.P. Lond., Senior Medical Registrar; BROCKBANK, W., M.R.C.S., L.R.C.P.; BROADHURST, W., M.B., Ch.B.; and FAIRBROTHER, R. W., M.B., Ch.B., House Physicians. LAMBERT, V. F., M.B., Ch.B.; MORRIS, L., M.B., Ch.B.; BACON, W. B., M.B., Ch.B.; FILDES, W. E., M.B., Ch.B.; BROMLEY, J. F., M.B., Ch.B.; and EDWARDS, N. L., M.B., Ch.B., House Surgeons. GALLOWAY, R. L., M.B., Ch.B., second Surgical Registrar. RYRIE, B. J., M.B., Ch.B. (Senior), and HAWORTH, A., M.B., Ch.B. (Junior), Pathological Registrars. POSTON, Mrs. MARGARETTE McL., M.B., B.Ch., B.A.O., Anæsthetist (Central Branch). PATERSON, R. S., M.B., Ch.B., Senior Assistant Medical Officer to the Radiological Department.

Vacancies.

For further information refer to the advertisement columns.

Birmingham General Hospital— Director of V.D. Dept. £600.
Birmingham, Queen's Hospital.—Med. Reg. £100.
Birmingham Union, Dudley-road Hospital.—Res. P. £650.
Bristol Royal Infirmary.—H.P.'s, H.S.'s, Obst. H.S., Cas. and Ophth. H.S. Each £80. Also Dental H.S. £116.
Camberwell Infirmary.—Asst. Med. Supt. £500.
Carlisle, Cumberland Infirmary.—Res. M.O. £175.
Edinburgh Royal Mental Hospital.—Asst. P. £350.
Evelina Hospital for Children, Southwark, S.E.—P. to Out-patients.
Glamorgan County Mental Hospital, Bridgend.—Jun. A.M.O. £350.
Hampton, Middlesex, Infant Welfare Centre.—Female Medical Practitioner. £1 11*s.* 6*d.* per session.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Res. M.O. £150.
Kent County Ophthalmic Hospital, Maidstone.—H.S. £300.
Malay States.—M.O.'s. and Health O.'s. £616.
Manchester, St. Mary's Hospitals.—Res. Obstet. S. Res. S.O. Each £200. Also two H.S.'s. Each £50.
Manchester, Victoria Memorial Jewish Hospital.—Two additional Anæsthetists. 50 guineas, with 10*s.* 6*d.* per attendance.
Nottingham General Hospital.—Res. Cas. O. £250.
Royal Chest Hospital, City-road, E.C.—P. to Out-patients.
Royal Earlswood Institution, Redhill, Surrey.—Jun. Asst. M.O. £250.
Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Three Hon. Anæsthetists.
St. Bartholomew's Hospital.—Refraction Asst. One guinea per session.
St. Luke's Hospital, Chelsea, S.W.—Third Asst. M.O. £325.
St. Marylebone Hospital, Ladbroke-grove, W.—Third A.M.O. £300.
Sudan Government, Medical Dept.—Medical Inspector. £E.720.
West London Hospital, Hammersmith-road, W.—Hon. Med. Reg., Hon. Surg. Reg., and Hon. Obstet. Reg.
Windsor, King Edward VII. Hospital.—Hon. Asst. P.
Worcester General Infirmary.—Res. M.O. £200.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Markfield, Leicestershire.

Births, Marriages, and Deaths.

BIRTHS.

DICKSON.—At a nursing home, London, on 30th Jan., to Ethel (née E. S. Grey), wife of Flight-Lieutenant E. D. Dalziel Dickson, M.B., Ch.B., F.R.C.S., R.A.F., Lime Tree House, Wendover, Bucks—a son.

DUNCAN.—On Jan. 29th, at Purulia, India, the wife of Major A. W. Duncan, I.M.S., of a daughter.

RAYNER.—On Feb. 3rd, at a nursing home, wife of Francis L. Rayner, 65, Hornsey-lane, N. 6, of a daughter.

SUTHERLAND.—On Jan. 30th, at a nursing home, the wife of Halliday G. Sutherland, M.D., Canynge-road, Clifton, of a son.

MARRIAGES.

KNOBEL—RINTOUL.—On Feb. 4th, in London, William Bernard Knobel, M.D., M.R.C.P., to Ellen, eldest daughter of Mr. and Mrs. George Rintoul, of Angers, France.

DEATHS.

DE MORGAN.—On Jan. 27th, at St. Leonards, Campbell William De Morgan, M.B., of Montagu House, Upper Norwood.

HARDCASTLE.—On Feb. 2nd, at Sydenham-terrace, Newcastle-on-Tyne, William Hardcastle, M.B. Lond., L.R.C.P., aged 51 years.

WHITE.—On Jan. 30th, at Cannes, Lieut.-Colonel Joshua Chaytor White, C.M.G., I.M.S. (retd.), aged 59.

WILKIN.—On Jan. 27th, at Rose Ash, North Devon, John Frederic Wilkin, M.D., aged 84.

*N.B.—A fee of 7*s.* 6*d.* is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

THE "LITTLE THINGS" IN DIAGNOSIS AND TREATMENT.[1]

BY ARCHIBALD YOUNG, M.B., C.M., B.Sc., F.R.F.P.S. GLASG.,

PROFESSOR OF SURGERY, ANDERSON COLLEGE OF MEDICINE, GLASGOW; DEAN OF THE COLLEGE; VISITING SURGEON, WESTERN INFIRMARY, GLASGOW, ETC.

I HAVE often been impressed by the importance of comparatively insignificant details in the construction of a clinical picture. I have often tried to impress on my students, and on my house surgeons, the importance of attention to detail, both in the examination of a case, and in the construction of a diagnosis, on the basis of the facts of a clinical history, and the ascertained facts of a carefully made examination. I have often found, for myself, both the value of trifles apt to be overlooked, in the making of a reliable and correct diagnosis, and—not seldom, I regret to say—the value that they *would* have had, if they had been given due weight, in the prevention of error in the making of a diagnosis. Only too often, I am sorry to say, have I myself been able to look back, after the event, on a case, wrongly, or at least incompletely diagnosed, and been able to see how, if only due attention had been given to some symptom or sign, and its importance properly appreciated, a very different diagnosis, possibly a very different prognosis, would have been given, and, perhaps, a very different—even more favourable—issue would have resulted.

The Pathognomonic Sign.

You have heard, I dare say, the term "pathognomonic" applied to a certain symptom, sign, or group of symptoms and signs in a given disease, and perhaps you may have been—as I was in my student days—somewhat unduly impressed by such a term. One of my old teachers used it a great deal. He spoke of a reversal of the pulse-respiration ratio as "pathognomonic" of pneumonia, of the serpiginous outline of a syphilitic ulcer as "pathognomonic," of the barrel-shaped chest as "pathognomonic" of emphysema, and so on. In many cases his diagnosis of such conditions was perfectly correct, and the signs referred to led to a just appreciation of the lesion present, but it soon became evident to me that a scientific diagnosis demanded much more than that.

The Syndrome.

Nowadays you must have heard many speak of such and such a "syndrome," meaning, by the term, a combination of symptoms and signs, which, taken together, are regarded as characteristic of some particular disease—some symptom-complex, which being present, and actually demonstrated, or demonstrable, points unerringly to the correct diagnosis. While it may be worth while to recognise such combinations, as indicating—even with considerable emphasis—the direction in which the correct diagnosis should be sought, there is some danger of our falling into much the same error that the use of the term "pathognomonic" was apt to lead to.

It may be conceded that certain symptoms and signs, or certain combinations of these, generally or even always occur in particular diseased conditions, but they are not always equally developed or evident; in come cases they may be obscured by other symptoms and signs. It is at least true to say that a too slavish adherence to the "pathognomonic," or to the "syndrome" idea is liable to lead to error, and it is equally true to say that it does not tend to the cultivation of the really scientific habit in construction of a clinical diagnosis.

Important Signs.

There are, however, many examples of symptoms or signs which furnish useful indications of the nature of the disease from which a patient is suffering. Take, for instance, the diagnostic significance of pain, local or referred, in all manner of conditions. Several years ago, when I had under my professional care a young girl on whom I operated for a very acute mastoiditis, the girl's father mentioned to me, quite casually, how his wife was much troubled by "rheumatic" pains in her shoulder, and that she was often simultaneously afflicted by so-called bilious attacks. I was not then being consulted professionally on the matter; I did, however, remark, even then, "What about gall-stones?" The husband reminded me of my remarks a year

[1] An abstract of a lecture delivered to the Queen Margaret Medical Club, Glasgow, on Nov. 19th, 1923.

later, when I was sent for to see his wife professionally. She had suffered much, meantime, and had been under the care of several physicians, having been labelled as suffering from panniculitis, rheumatism, neuritis, &c. She had had several courses of systematic massage, and no end of anti-rheumatic remedies. I saw her, found her slightly jaundiced, gave a diagnosis of gall-stones which proved correct, removed her gall-bladder and the gall-stones, and all her symptoms disappeared.

Or, take another example. Suppose you are confronted with a doubtful abdominal case, in which you are told that the bowels act with normal frequency. It is seldom advisable to accept, without personal verification, the assurance either of patient or of friends. A simple answer in the affirmative to the question, "Are the bowels all right?" should rarely be taken as sufficient. You must learn exactly how often the bowels act daily, weekly, &c., and of any growing difficulty or frequency, any accompanying pain, tenesmus, mucus or blood in the stools; you must see the stool for yourself. You will get many surprises, and, I am very certain, much valuable information. I have found an astonishing failure on the part of doctors, nurses, house surgeons, patients even, to prosecute properly this line of examination. In my wards I have no difficulty now—but at first I found it more difficult—to carry out a proper examination of the stools. My regular march to the bath-room to inspect the results of enemata has long ceased to furnish a theme for amusement, for we have had numerous examples of the valuable information to be obtained there.

One might multiply such examples almost indefinitely, but let these examples suffice for the purpose. I do not wish to dwell on these instances as suggesting the possibility of building a diagnosis on single, or even on a few, symptoms or signs—that would be, once again, our old "pathognomonic" sign—but I wish to emphasise the desirability of taking into consideration all the striking signs in constructing a clinical picture.

Signs in Eye Conditions.

I am indebted to Dr. Maitland Ramsay for the following note regarding particularly suggestive symptoms and signs in the diagnosis of different eye conditions:—

"Unconsidered trifles frequently missed by the unobservant, are often of great value, both in diagnosis and prognosis. Every branch of medicine furnishes examples, and these instances from ophthalmology may be of interest.

"A patient may complain, in an indefinite manner, of his sight, and of a feeling of discomfort in his eyes, but, at the time of examination no abnormal signs can be detected. Nevertheless, if that patient, in the course of conversation, says that, during the previous year, he has had to change his spectacles several times, and, in reply to an inquiry, admits that he has noticed, on many occasions, a rainbow-like halo round a lamplight, a diagnosis of glaucoma can be made without much hesitation.

"Or another patient, with the same general complaint of difficulty in seeing, so as to recognise a friend in the street, or to read a printed page, may state that, to him, blue has now become a predominant colour; that, for example, when he looks at a bunch of sweet peas, they all appear to be in different shades of blue, or, when in a theatre, the chorus girls all appear to be dressed in blue. In such a patient, careful testing will reveal, in all probability, a central scotoma for red and green, and a diagnosis of toxic amblyopia may be established quite readily, even although the ophthalmoscopic findings are negative. Such a patient, when his colour defect is pointed out, may then describe, if he be at all observant, how he has been struck, of late, when walking along the street, by the almost corpse-like pallor of the passers-by; or, if he is a golfer, he may admit the difficulty he has been having lately in distinguishing the red flags on the greens, while he can see the white flags with comparative ease; if he is a billiard player, he may confess that, in certain positions, he cannot see the red ball.

"Another patient may complain that, although he sees to read, he has difficulty in passing from one line to another, and is constantly losing his place. His friends, perhaps, have noticed that he only eats the food on one side of his plate, and that, if anyone approaches him from behind, say, from his left-hand side, he does not see the person. Almost certainly, that patient is suffering from hemianopia."

Dr. Maitland Ramsay also drew my attention to a note which appeared in THE LANCET of Oct. 20th, 1923, regarding an investigation being conducted in Leicester into the causes of "felting" of underwear. The writer of the note was reminded of "the late Sir William Osler's tale of the ailing child of wealthy parents; it was before the days of vitamins and a numerous flock of consultants stood baffled around the puling infant. At last an aged practitioner took the child's napkin, extracted it with water, and applied the guaiacum test. The test was positive and scurvy stood revealed." This story furnishes a good example of an "unconsidered trifle," appreciation of which might be productive of a good result.

Diagnosis and Prognosis.

The term diagnosis literally connotes "knowing through" or "through and through." Actually, we conceive it as involving the due consideration of every kind of evidence, the placing of each factor in its proper relation to all others, a correct appraisement of anatomical relations, the facts of known physiology and of pathology, and their importance in relation to a particular lesion. Ætiology, also, has come to have a greatly added importance in the making of any diagnosis. In the beginning of things medical, diagnosis was not given so restricted an application as we are apt to give it to-day; nor was there the same tendency to separate it from what we now speak of as prognosis. Or, rather, it might be more correct to say that prognosis, a more ancient term than diagnosis, had a much wider and more comprehensive scope. I have heard the late Sir William T. Gairdner emphasise the fact that Hippocrates meant by "prognosis" not merely "fore-knowledge," but also a process of talking of, or interpreting, the disease beforehand—prior, that is, to the patient's recounting of his symptoms. Thus the use of the word by Hippocrates was not exactly like our present-day application of it. The close association of prognosis with diagnosis has not only the warrant of antiquity, but the very obvious justification of logical connexion. The prognosis in any case of disease hinges largely on the accuracy and completeness of the diagnosis, and it is the prognosis that the patient, or his friends, chiefly want.

In the course of a recent conversation with Sir James Mackenzie, the latter took my breath away at one point, by suddenly saying, "What does diagnosis matter? It is of very little importance. What really matters is prognosis. Is the man going to die? When is he going to die? How is he going to die? Why is he going to die? How does cancer kill a man? Why do our cancer patients die? What is it that kills them? It's not the cancer. What is it?" And so on. There is obviously very much we have still to learn. There are very many problems still to be solved. And, probably most of these solutions, when achieved—if they ever are—will be reached, not as the result of any astounding discovery, but as the result of appreciating in their proper meaning, and in appraising at their proper value, sundry details—little things, unconsidered or imperfectly considered, whose importance has been missed.

Treatment.

There remains for consideration the aspect of the subject concerned with treatment. The good physician or surgeon, as a rule, pays most attention to the little details: treatment must be based upon a constant watchfulness of the patient's progress. A sudden, perhaps trifling, change for better or for worse, should not go unnoticed; its immediate, or, at least, its early recognition may count for a very great deal in the prospects of the sufferer. Observation is wanted just as much in treatment as in the making of a diagnosis, and changes occurring during treatment may greatly influence prognosis.

Suppose you are watching the progress of a case, and, for days, perhaps, things have been going badly. The patient not only seems to be getting steadily worse, but he may even seem to have given up the fight himself. The Vis medicatrix naturæ no longer shows any sign of effort after recovery. You go in to see him one morning, and you appreciate a change for the better at once. He has had a shave—a thing he had no idea of for, it may be, days before. In other ways as well he has begun to recover his self-respect—shall we say?—and he shows it. He is going to make a fight for it yet—you know it almost instinctively. Or, to take another example, suppose you have a critical abdominal case, and, spite of all treatment, medical or surgical, improvement tarries. You find, some day, that the tongue, previously dry and brown and cracked, has begun to clean, and has become moist, and, probably you very soon find other evidences of improvement, such as disappearance of tympanites, cessation of vomiting, relief of nausea, return of desire for food, lessening of thirst. Your outlook for the patient is at once affected for the better.

A complete reversal of either of the pictures I have just described would, on the other hand, require to be given corresponding weight.

One aspect of the problem of little things is that which deals not so much with the cure of the patient, in the usual acceptation of the term, as with the *care* of the patient. To a weak and helpless patient, whose bodily powers are already much below par, the most trifling ills or discomforts

are apt to be magnified greatly, and their individual as well as their combined and cumulative effect may go far to turn the scale towards a less favourable result than might otherwise be looked for. A crumb, a crease in the sheet, a slight unevenness in the mattress, a noise, uncontrolled light, a buzzing and persistent fly, disordered bedclothes, too hot or too cold a water-bottle, a harsh word from an attendant, a slip-shod serving of a meal, may have great influence for evil upon the prognosis. On the other hand, one can hardly over-estimate the good effect that may be exerted by the reverse conditions. Here comes in the value of efficient nursing; the efficient nurse is faithful in small things as in great.

And the efficient doctor is the one who, with a good scientific equipment, can combine fidelity in observation and unremitting attention to the daily care of his patient, with the gift of sympathetic realisation of his patient's aches and pains. I have known great surgeons, and celebrated physicians, who were utterly incapable of "caring for" their patients, being devoid of sympathy, ignorant of the many simple devices or remedies which can accomplish so much in the way of imparting added comfort, and intolerant of peevishness or fretfulness.

I can never be too thankful for the good fortune which brought me, at a certain stage of my professional career, into contact with a man, endowed with many gifts, whose greatest achievement was in the after-care of his patients. From him I learned how to deal with such disturbing factors as flatulence, thirst, digestive defects contingent on many surgical conditions, the after-care of abdominal operations, preparations for an operation of any kind, special details in the preliminary preparations for rectal operations, and so on. I learned how much the average patient came to lean on his own doctor; how he appreciated consistent personal care; how he resents, in many cases, his being relegated to the care, soon after operation, of an assistant or nurse, however skilled and attentive. I have come to realise, since, how much the patient counts it for good that the surgeon himself shall dress his wound.

In what I have just said I have been concerned to emphasise the fact that the actual treatment of the patient is something far transcending the removal or eradication of the disease from which he is suffering. The art of medicine is a big thing indeed; viewed solely from the therapeutic point of view, it is big enough. None the less true is it however, to say that the "little things" count for very much, if not, in fact, to remove dis-ease, at least to make dis-ease more bearable, or less unbearable. The sympathetic touch, the gentle word, the watchful eye, are more than mere figments of imagination, mere interesting details used by the sentimentalist in writing of the rôle a good nurse and a good physician or surgeon may aspire to fill. The larger issues, the great principles, the immutable laws remain; what I have here presented is but a fragment, a side issue, an aspect of study, a little bundle of comments from experience.

SMOKE ABATEMENT.

A BOOK on Smoke Abatement[1] appears opportunely at a time when, as Dr. Cyril Banks, medical officer of health of Halifax, points out in a foreword, there appears to be a revival of public interest in the problem of a pure air-supply. The author aims at giving sanitary inspectors and public health officials a proper understanding of the sequence of events in a furnace, and of the fundamental principles involved in the use of the various instruments and appliances designed to secure complete combustion and to prevent unnecessary smoke. This object has been attained in a satisfactory manner, and the numerous illustrations contribute valuable assistance thereto. All interested in the subject will agree with Mr. Clinch that it is a pity that stoking has hitherto been regarded as an unskilled trade. Untrained inspectors are the logical sequel. One of the hopeful suggestions in the book is that, if the inspector knows his work, the stokers are only too willing to learn from him. If we are to do any good in this matter of industrial smoke prevention we must have skilful stokers and well-trained smoke inspectors. Let us hope that the enthusiasm aroused by the clean air of our industrial towns during the coal strike will not be damped down by the specious plea that the smoke from the domestic chimney, owing to the lower temperature at which it is given off, is more injurious than the smoke from the factory chimney. We want to reduce both varieties to a minimum. Mr. Clinch seems to think that an Englishman's love of an open fire is incurable, and pins his faith to low-temperature coke as a remedy for domestic smoke. We fancy, however, that the need for labour-saving in these days has converted a good many lifelong fire-pokers to the use of gas. Mr. Clinch's book ought to help to keep alive interest in this important problem, and will be of value, not only to public health workers, but also to mill-owners and managers and all who have an interest in the proper management of factory chimneys.

[1] The Smoke Inspector's Handbook or Economic Smoke Abatement. By Herbert G. Clinch, Chief Smoke Inspector, Halifax. London: H. K. Lewis and Co., Ltd. 1923. With 59 illustrations. Pp. 136. 7s. 6d.

WOOLLEN UNDERWEAR AND BODY BELTS.

A NUMBER of garments, together with samples of materials used by Messrs. Lyle and Scott, Ltd., of Hawick, in the manufacture of underwear, including body belts for adults and children, have been submitted to us for examination. The specimens comprised bleached and "natural" fabrics of varying qualities. They were soft, well woven, and a microscopic examination showed that the fibres of all the specimens responded to the tests for pure wool. It is a matter of importance in the case of articles for use next to the skin that when claiming to be wool they should consist of this material and nothing else.

PHYSICAL ENERGY.

IN an entertaining little book Bombardier Billy Wells (London: T. Werner Laurie, Ltd. 1923. Pp. 153. 3s. 6d.) sets out to show how physical and mental energy may be developed by the practice of boxing. By itself, the book would not be particularly interesting, but coupled with the name of its distinguished author, it at once attracts attention. Physical energy is largely the gift of the gods; books may teach us how to conserve it, but it must exist before it can be trained, and essays on physical energy may be as useful (or useless) to the listless as advertisements of hair culture are to the bald. But though it is doubtful if readers of this book will gain much physical energy from a study of the author's views, they will find much of interest in his many personal touches. The intention of this book is to show how boxing may become a rational method of physical culture. The boxer is contrasted with the purely muscular weight-lifter, the latter being likened to an elephant, the former to a Derby winner. In this connexion two interesting sculptures are reproduced. The first is that of "Physical Energy," by G. F. Watts, showing a mounted equestrian; the second is that of "The Farnese Hercules," whose massive muscles would do credit to a Shire horse. It is stated in the preface that this book has been written in collaboration with an eminent medical authority, and a reference to the last chapter on spinal nerve pressure raises the suspicion that the "eminent medical authority" is greatly intrigued by the modern teachings of osteopathy. The reader is informed that "if one of the vertebræ should become even slightly displaced, the channel is narrowed and the nerve within it is pressed upon, causing a great variety of symptoms accompanied by disturbance of one or more of the bodily organs." Pathology of this stamp is not impressive, but the Bombardier's reminiscences of his steps up the ladder of fame are worth reading.

HEALTH CONDITIONS IN BECHUANALAND.

Mr. J. Ellenberger, Government Secretary, in his report on the affairs of the Protectorate for the year 1922, states that the returns of diseases among the European and native populations show a low degree of incidence and severity all round. The prevalent diseases have been malaria, with its complications and sequelæ, syphilis, and influenza. With regard to malaria, there was during the year a remarkable absence of outbreaks affecting entire communities or areas. The total returns represent a collection of infrequent and mild individual cases scattered over a wide extent of territory. There has been a marked increase in the return of venereal diseases. This is, however, more an indication of extended observation, as connected with the special work of the dispensaries provided for the purpose, than of absolute increase. The influenza outbreaks were mild and of the ordinary catarrhal type, most of the cases recovering after a week or ten days. Epidemics of measles, unattended by any special features of severity or mortality, occurred at Serowe and elsewhere. The total number of cases, both indoor and outdoor, treated during the year was 1700, with, so far as ascertainable, a mortality of 1·06 per cent. The total rainfall for the year ended March 31st, 1923, was 23·192 inches. The Protectorate is bounded on the south and east by the Union of South Africa, on the north-east by Southern Rhodesia, on the north by the Zambezi and Clobe Rivers, and on the west by the territory of South-West Africa. It has not been surveyed as a whole, but its area is estimated at 275,000 square miles. It lies roughly at between 2000 and 5000 feet above sea level, and only a few people live at the cooler altitudes of from 4000 to 5000 feet. The portion of the country inhabited by the greater number of both Europeans and natives is adjacent to the only line of railway, which passes through the eastern side of the Protectorate for a distance of 403 miles.

Hunterian Lecture
ON
TESTICULAR GRAFTS.

Delivered before the Royal College of Surgeons of England on Feb. 4th, 1924,

BY KENNETH M. WALKER, F.R.C.S. ENG.,
SURGEON IN CHARGE OF GENITO-URINARY DEPARTMENTS, ROYAL NORTHERN HOSPITAL AND MILLER GENERAL HOSPITAL FOR S.E. LONDON.

IT is the custom as a prelude to the delivery of one of these lectures to trace some link between the subject chosen for discussion and the work of the illustrious man whose name the lecture serves to commemorate. On the present occasion this connexion is particularly intimate, for it is recorded that in 1780 John Hunter succeeded in the task of transplanting the testicle of a dog. Although the full import of this experiment does not appear to have been realised at the time, the fact that transplantation had been achieved may well have acted as an inspiration to Berthold and other pioneers of grafting in the work that they carried out nearly a century later. It will be seen, therefore, that the subject of testicular grafts that I have chosen for my present lecture is singularly appropriate. Before, however, proceeding to my main theme it will be convenient to say a few words on the subject of treatment by means of testicular extracts.

TESTICULAR EXTRACTS.

Brown-Séquard was the first to call attention to the use of extracts of animals' testicles as a therapeutic agent. His experiments were conducted on his own person and consisted of injecting subcutaneously a freshly prepared extract of the testicle of the dog. He claimed that as the result of these injections a definite improvement in his health was brought about, accompanied by a great increase in muscular and mental energy. Indeed, so marked was the effect that he was enabled, after having abandoned his researches on account of failing health, to return to his laboratory, and to remain there hard at work up to the time of his death at an advanced age.

Since the time of Brown-Séquard testicular extracts have been extensively employed in clinical medicine, although observations on the subject of a scientific or exact nature are remarkably few. Zoth and Pregl have proved that subcutaneous injections of orchitic extract do not of themselves produce an increased capacity for muscular effort, but that when the injections are combined with muscular exercises ergograph records show an increase of as much as 50 per cent. in efficiency. However, that the injections are not entirely free from danger has been demonstrated by Loisel, who found that the ovaries and testicles of fishes, frogs, birds, and mammals all contained toxic substances which, when injected subcutaneously, may provoke serious symptoms or even death. On account of this, Brown-Séquard's methods of subcutaneous injections have to a great extent been abandoned in favour of oral administration.

A great number of commercial preparations of orchitic extracts are at present on the market. My own observations have, in the main, been made with a special extract prepared at the Lister Institute from fresh bull's testicles. This extract has been used on a large scale at St. Mary Abbots Hospital, Kensington, and through the courtesy of Drs. V. Korenchevsky and J. A. Lumsden Cook, I have been allowed to examine some of the patients under treatment. Accurate records have been kept throughout the course of treatment, and certain simple psychological tests of memory, attention, and fatigue carried out by an observer trained in these methods. As the result of what I have seen, and of my own previous experience, I have come to the conclusion that extracts of testicle, when administered by the mouth, are entirely without effect. It is true that in a certain number of cases an improvement in general health or in mental energy has been claimed after taking the extract, but in none of these cases have I been able to convince myself that this was not the result of mental suggestion. I am strongly of the opinion that the active principle of testicular extract, whatever it may be, is destroyed by the digestive juices, and that the only hope of obtaining results is by the use of subcutaneous injections. Pariser, it is true, has made observations of a substance prepared from testicular tissue, and administered by the mouth, which he claims is not so destroyed, but his claims have not yet been substantiated.

Of preparations available for subcutaneous or intravenous injections, such as testogan, prepared from a formula of Dr. Iwan Bloch, I have as yet but little personal experience, but I am convinced that it is in the discovery of an effective preparation of this nature that the chief hope of the future progress of the organotherapy of the testis lies. However brilliant the results that the implantation of a testicular graft may sometimes give, it is obvious that severe limitations are imposed on such a method of treatment, and that as was the case in the organotherapy of the thyroid, but little advance will be made until the use of grafts is replaced by that of a really efficient extract.

TESTICULAR GRAFTS.

The partial success that followed the use of thyroid grafts towards the end of the last century revived interest in the subject of gland transplantation in general, and it was not long before further attempts were made to remedy testicular deficiency by the use of grafts. The difficulty of obtaining material has resulted in an extensive trial of animal grafts, and although it has long been obvious that these are rapidly absorbed, good results have sometimes been obtained owing to the fact that during the process of absorption a certain quantity of internal secretion finds its way into the blood stream. L. L. Stanley, who has worked particularly along these lines with animal grafts, has reported very favourably on their use. His method of implantation, although seemingly crude, would appear to have had the merit of enabling the treatment to be carried out on a large scale, his own observations being made on 656 prisoners in the Californian State prison. All that Stanley found necessary was to cut up the testicle into very small fragments and to inject these through a syringe with a large calibre needle into the subcutaneous tissue of the abdominal wall. Strange to say, very little local trouble would appear to have followed this crude method of implantation, the grafts being palpable as small subcutaneous nodules until they became completely absorbed a few months later.

In order to avoid the fate that invariably overtakes grafts obtained from the lower animals, Voronoff in 1920 made use of a testis taken from an anthropoid ape. As the result of this and of many subsequent operations he has come to the conclusion that grafts obtained from the higher apes are capable of surviving in the human body for an indefinite period. In his "Greffes Testiculaires," published in 1923, he has reported cases in which the improvement following a graft has persisted for as long as three years, and he himself is not inclined to set any limit to the duration of the benefit that may result from their use. Other workers, notably Lydston, Lichtenstern, Lepinasse, and Morris, have used for the purpose of grafts human testicles obtained from recently executed criminals, from patients dying as the result of accident or of certain specified diseases, and from cases of ectopia testis. In my own work I have made use of the last-named source, and am convinced that it is the most practical method of procuring suitable material for this purpose. Whatever may have been Voronoff's results with grafts derived from the higher apes, it is obvious that the chances of success are greater if human tissue be used. An ectopic testis,

deficient though it may be as regards spermatogenesis, is usually well-developed from the point of view of internal secretion. In those cases in which there is a healthy and normally placed testicle on the opposite side, and in which the shortness of the cord is an obstacle to orchidopexy, removal of the misplaced organ is justified, for, as Lipschutz has shown, as little as 1 per cent. of the total testicular tissue is sufficient to maintain masculinisation. Most of the material used in my own series of cases recorded below was obtained from young donors between the ages of 10 and 22, in whom the secondary sex characters were well developed. Previous to operation a Wassermann test was performed, and a careful examination carried out in order to exclude the existence of tuberculosis, malaria, or any other constitutional disease. The operative technique, the type of case selected for grafting, and the results obtained will now be considered.

OPERATIVE TECHNIQUE.

Many different sites have been selected for the implantation of grafts, the most commonly favoured being within the peritoneal cavity or in a subperitoneal pocket, in such a muscle as the rectus abdominalis, within the cavity of a long bone, in the spleen, in the subcutaneous tissue and, in the case of testicular grafts, within the tunica vaginalis of the scrotum. It has been shown that the healing in of a transplanted gland is invariably preceded by a transient phase of degeneration which, slight at the periphery, becomes more intense towards the centre. Until vascularisation can take place the graft is dependent for its nutrition on osmosis from the surrounding tissues. Once the blood-vessels have found their way from the periphery towards the centre of the graft a process of regeneration starts, the surviving cells of the graft proliferating and the central necrosed area becoming transformed into connective tissue. It will be seen, therefore, that the critical period in the history of a graft is the period prior to vascularisation during which the transplanted organ is dependent for its nourishment on osmosis. Now the implantation of a graft within the peritoneum or in a serous sac like that of the tunica vaginalis has a definite advantage. It provokes a certain amount of serous exudation, which furnishes an excellent medium for the survival of the graft during these critical days. For this reason in my own work I have followed the technique of Lydston and Voronoff, and have placed my grafts within the tunica vaginalis. Only in those cases in which, owing to previous disease or operation, the vaginal cavity has become obliterated have I had recourse to Lichtenstern's method of embedding grafts in the rectus muscle, and even in those cases I have made a practice of placing an additional graft in a subperitoneal pocket. When the tunica vaginalis has been the site of previous inflammation, as in most cases of genital tuberculosis, or when difficulty is found in identifying the vaginal cavity on account of partial obliteration, it is useless to persist in any attempt to place a graft in the scrotum. In those cases in which I have infringed this rule (see Case 6) the grafts have either failed to vascularise or else have been rapidly absorbed.

The actual technique of the operation is as follows. The donor having been anæsthetised, the misplaced testicle is removed with as little trauma as possible, and if practicable surrounded by its serous sac. Until required it is wrapped in gauze wrung out in saline and placed in a sterilised bowl. Although the implantation of the graft can be carried out under local anæsthesia, I prefer the use of a general anæsthetic, as in my opinion it is best to avoid the risk of damage to the tissues through the infiltration of novocain. An incision is made in the upper half of the scrotum and the cavity of the tunica vaginalis opened. Bleeding-points are then tied, special attention being paid to hæmostasis throughout the whole operation since post-operative bleeding is likely to jeopardise the safety of the graft. The testicle to be grafted is then removed from the bowl in which it has been stored, the sac opened and the body dissected away from the epididymis. The testis is then divided into two halves by sagittal section and the halves subdivided into three. Each of these portions is then attached to the tunica vaginalis and anchored in position by fine catgut sutures in such a way that the glandular surface of the graft is in contact with the serous surface of the tunica vaginalis. In order to encourage vascularisation the tunica vaginalis may be lightly scarified as a preliminary to the implantation of the graft. In those cases in which a testicle exists in the recipient a graft may conveniently be placed in the digital fossa between the epididymis and testis (Fig. 1). Care must be exercised to ensure that no two grafts are in contact, as such contact is likely to cause necrosis. After making sure that the three grafts are well placed, I close the tunica vaginalis by means of a continuous catgut suture, and bring together the scrotum in two layers, one line of sutures uniting the deep fascia and the other the skin. The same proceeding is then carried out on the opposite side. It is unnecessary to point out that the strictest asepsis must be observed throughout the operation.

FIG. 1.

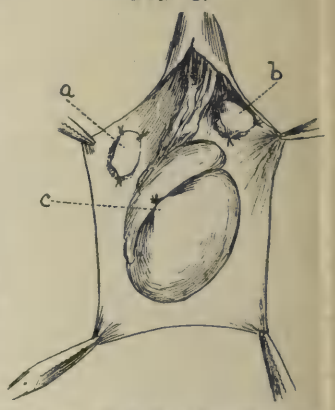

Diagram showing technique of testicular grafting. The tunica vaginalis has been laid open and three grafts (*a*, *b*, *c*) inserted. *a* and *b* are attached to the parietal layer of the tunica vaginalis, and (*c*) inserted in the digital fossa of the testis by means of fine catgut sutures.

Dressings are then applied and the patient is returned to bed. For 24–48 hours after the operation a certain amount of swelling of the scrotum is usually noticed, the swelling being due to the transudation of the serous fluid into the vaginal cavity; this transudation, as has previously been pointed out, plays an important part in maintaining the life of the graft during the critical period that precedes its vascularisation. At the end of a further three or four days this local reaction subsides. The patient may usually be allowed up, wearing a suspensory bandage for from 10 to 14 days from the date of the operation.

INFLUENCE OF TESTICULAR GRAFTS ON THE PATIENT'S METABOLISM.

It was felt that a few cases of testicular grafts carefully examined before and after treatment would furnish more reliable evidence of the value of the method than a larger number in which the examination had been less complete. In the cases recorded in literature by other workers the proof that the transplant has had effect rests entirely on clinical grounds, reliance being placed on the patient's general appearance, his capacity for greater muscular exertion, his mental condition, and his sexual history. These criteria, although of undoubted value in assessing the effect of a graft, are not absolutely reliable, for they are all likely to be influenced by the factor of mental suggestion. In order to obtain data on which more confidence could be reposed in several of the cases recorded below, a careful investigation was carried out of the metabolism of the patient before and after operation. Although little is at present known of the influence exercised by the gonads over metabolism, it is, at any rate, certain that such an influence exists. Heymans has shown in the cock that total castration diminishes metabolism by 20–25 per cent., and that partial castration diminishes the respiratory exchange by some 15 per cent. Löwy and Richter, working on castrated dogs of both sexes, found that after castration metabolism was reduced

in the proportion of 14–20 per cent. per kilo. of body-weight, and that this reduction was maintained for months or even years. They also concluded that the reduction of metabolism after castration is due to a diminution of the processes of oxidation, but that the obesity that not infrequently follows may be constitutional and is not necessarily degenerative. The work of Dixon, Mackenzie Wallis, and others on ovarian secretion suggested to me that alterations in the internal secretion of the testis might equally well be rendered evident by the employment of sugar-tolerance tests, and that valuable evidence of the "taking" of a testicular graft might, therefore, be obtained by carrying out careful blood-sugar estimations, before and after operation. This has been carried out for me by Dr. P. O. Ellison, assistant pathologist to the Royal Northern Hospital, whose results are appended to the case reports given below. To him my thanks are due for the care and interest he has shown in these investigations, as also to the Medical Research Committee for providing me with the necessary apparatus. Investigations of metabolism have been kindly carried out for me by Prof. Winifred Cullis, and her results are also appended.

Although the observations on the blood-sugar curves are too few to allow of any deductions concerning the influence of testicular secretion on sugar tolerance, they have served their purpose in demonstrating that, as a result of the graft, an alteration in tolerance has taken place.

CASE 1.—Patient, aged 29, wounded July, 1916, a fragment of shell lodging in the pubis just at the root of the penis, destroying the right testicle and causing an extensive hæmatoma of the abdominal wall. The remains of the right testicle were removed on reaching the hospital. Subsequently the left testicle atrophied as the result of interference with its blood-supply. At the time of wounding the patient's age was 23, and he was in every way normal as regards sexual development. He had married a year previously, had regular intercourse three or four times a week, and was athletic in his habits, representing his unit in boxing and running. Previous to the outbreak of war he had earned his living as a general labourer. Subsequent to the loss of the testes certain changes occurred. His weight dropped from 10 st. 4 lb. to 8 st. 13½ lb., and the growth of the beard diminished so that instead of shaving on alternate days as he had previously done he now shaved only every fourth day. There was complete loss of potency and absence of sexual desire. The bowels, which had previously acted regularly, now gave trouble, so that he was forced to take a purgative daily. Associated with these changes was a complete alteration in mentality; he lost interest in everything and the slightest effort produced fatigue, so that he could not even read the newspaper or a magazine. Half an hour's walk was sufficient to cause exhaustion, and after his discharge from the army he was compelled to give up his former work in favour of a less strenuous occupation. In addition to constipation and fatigue he complained of occasional "cold sweats" and of attacks of "giddiness" on bending down. The patient felt his condition so acutely that he readily consented to operation. Before grafting various laboratory examinations were made. Details of these are appended. In addition to these pathological investigations, and in order to obtain an unbiased estimate of the patient's psychology, he was sent to the National Institute of Industrial Psychology, and examined by Dr. G. H. Miles, whose report is given in extenso below.

Operation.—On Dec. 15th, 1922, under general anæsthesia, six grafts from the ectopic testis of a boy of 10 were inserted, three into each tunica vaginalis, according to the technique previously described. Convalescence was uneventful, the wounds healing by first intention and the stitches being removed on the eighth day. On the tenth day the patient noted the beginning of transient erections, which gradually became more frequent and stronger. He became conscious at the same time of an improvement in his general health. When seen five weeks later the erections were strong and well maintained and there was a definite return of sexual desire. The growth of the beard had increased so markedly that he was compelled to shave daily. From this time onwards he began to take more exercise and to show a renewed interest in life. Instead of sitting listlessly in a chair as was his previous habit, he bought newspapers, went three times to the theatre in one week, and became generally energetic. On Jan. 24th, 1923, he effected coitus with complete success. When seen on March 7th, nearly three months after his operation, he appeared to be in excellent health. His weight had increased from 8 st. 13 lb. to 9 st. 12 lb. and he reported that he was taking long walks, and had decided to abandon his sedentary occupation in favour of an open-air life. He had regular coitus with his wife and on two occasions he had in addition experienced a nocturnal emission. When examined, the grafts could still be felt in the scrotum, although they seemed definitely smaller than when previously examined.

A letter received on Jan. 21st, 1924, states that the patient remains in good health. Sexual desire is strong and he is able to gratify it. He reports that he is shaving daily, that the growth of hair is strong and is increasing in amount both on the chin and on the scalp. The results of the blood examination before and after operation, and Dr. Miles's psychological report are appended.

	Dec. 12th.	Jan. 22nd.
Hæmoglobin	90%	80%

(*b*) Left hand (average of six trials)	22·8	24·9	+ 9
Average improvement			+20

Note.—Marked improvement is shown in every type of test. The improvement is most striking in the "fatigue" test; well-marked in the test of general intelligence (particularly in tests of speed and attention); and least in the test of physical strength.

* Distinctly below the average level for young adults—viz., 100.

† Equivalent to the strength of grip of an 11-year old boy.

‡ Slightly above the average level for young adults.

§ Nearly equivalent to the strength of grip of a 14-year old boy.

Report on Respiratory Exchange, by Prof. Winifred Cullis.

The striking features in this case are the marked increase in oxygen consumption per square metre of surface after the operation, and the improved capacity for work. In the first two observations (although certainly some improvement had occurred at the time of the second observation), the patient was unable at the quick rate of breathing induced to obtain an adequate exchange. The quick, shallow breathing gave an oxygen intake less than that needed in the sitting position, and as a consequence there followed anoxæmia and faintness. In the third observation the condition was clearly improved. There was a better intake of oxygen during the exercise, and the response to the increased carbon dioxide was much better under control, so that in the recovery period, although the respiration was

still quick, the rate was compensated for by an increased depth of respiration and an adequate oxygen intake. Even in this observation, however, there was a tendency to failure at the fifth minute, corresponding to a slightly diminished intake; that, however, passed off quite quickly.

In both Case 1 and 2, therefore, there is a definite improvement as shown by the respiratory exchanges. It is hoped to make another series of observations at a later date.

* Began to feel faint.

CASE 2.—A naval officer aged 34. This case was referred to me by Dr. Langdon Brown, under whose treatment he had previously been. The patient showed a very marked degree of eunuchoidism with a history of having suffered from mumps complicated by double orchitis at the age of 13. The effects of this were not at first noticeable and from 17–21 he had led a fairly active sexual life. At 23 he discovered that his testicles were small in size and that he was losing interest in sexual matters. (Fig. 2.) At the same time there was a steady increase in weight. At 31 he was operated on for an abscess in the antrum of Highmore and one month after the operation was seized with violent headaches, terminating in vomiting. These cerebral attacks continued for two years, although repeated X ray examinations failed to reveal any trouble in the sinuses. In December, 1922, he consulted Dr. Langdon Brown, who discovered the eunuchoid condition and believing that his headaches were pituitary in origin put him on a combination of pituitary and orchitic extract. Under this treatment his headaches diminished in intensity. In May, 1923, he was referred to me for grafting.

His condition at that time was as follows: Age 34, height 6 ft. 1 in.; weight 14 st. 8 lb. The most striking feature about the patient was the development of fat, especially in the gluteal, supra-gluteal, and mammary regions. There was nothing unusual to note about the bony or muscular development, which appeared normal for a man of his age, except that the muscle tone was generally poor and the abdomen unduly prominent and pendulous. The complexion was somewhat striking, the skin having a faintly yellow tint and the cheeks being a dusky crimson.

Hair.—There was a marked alteration in the distribution of hair. The hair of the head was plentiful and curly, but except in the axillæ and on the pubis it was absent from the trunk. The arms and legs were equally smooth. The pubic hair, although plentiful, ended above in a well-defined horizontal line as in the female. There was no hair about the umbilicus or around the nipples.

External Genitalia.—The penis and scrotum appeared normal, the testes were undersized, unduly soft to the touch, and without testicular sensation. Cremasteric reflex absent. Prostate small. Vesicles not felt. There was marked development of the breasts with rosy nipples and complete absence of hair. The mental condition excellent, although previously the patient had suffered from prolonged bouts of despondency. Blood counts, sugar-tolerance tests, and metabolism curves are appended later.

Operation. — August, 1923, under general anæsthesia, six grafts were inserted, three into each vaginal cavity.

Course of Case.—Normal. The patient was discharged on the fourteenth day feeling well but otherwise no change was noted.

Blood Count.—R.B.C., 5,200,000; W.B.C., 12,000; hæmoglobin, 86 per cent.; colour index, 0·82. Differential: polymorphs, 53 per cent.; lymphocytes, 41 per cent.; large mononuclears, 4·5 per cent.; eosinophils, 1 per cent.; basophils, 0·5 per cent. Wassermann test negative.

Subsequent History.—No change was noted until Sept. 17th, 1923, when an increased growth of hair on the chin was detected, the growth in 12 hours being as much as previously occurred in 24. There was also a change in the character of the nipples, which had lost their rosy pink and taken on a more masculine hue. Nocturnal emissions were more frequent and erections stronger. There has been a steady diminution in weight since the operation (15 st. to 13 st. 9 lb.) and an increase in energy. He has had no headaches. Nov. 19th: No marked change since previous examination. There is certainly an increase in the rate of growth of hair, so that the patient now shaves daily. The deposits of fat in the breasts, buttocks, abdomen, and thighs do not appear to have diminished. The patient feels remarkably well, and is capable of greater muscular effort. In view of the fact that other glands are involved in the deficiency he has been placed on pituitary extract.

FIG. 2.

Case of eunuchoidism showing typical changes associated with lack of internal secretion of the testis. The arrangement of the pubic hair is as in the female, and there is marked hypertrophy of the breasts, increase of fat over the hips, and disappearance of hair on the body. The patient was treated by means of testicular grafts placed in the tunica vaginalis.

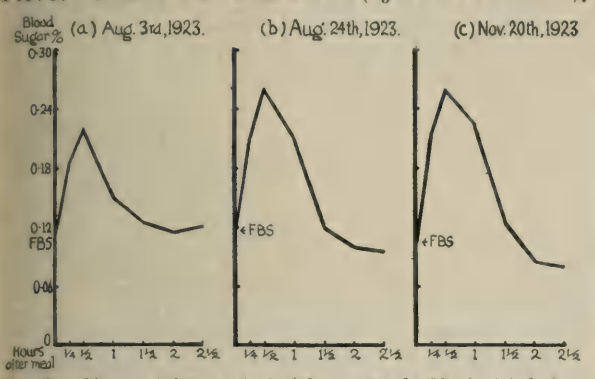
This case presents certain differences from Case 1. The departure from the normal is not so great, and the oxygen consumption (slightly below normal) is practically the same

for both observations. The respiratory quotient throughout is extraordinarily low, never rising above 0·79 and falling to 0·66 during the exercise. There is, however, in the second observation a marked improvement with regard to exercise; the oxygen consumption does not rise so greatly (the subject weighed 13 lb. less), and the return to the normal level is almost complete within three minutes of the cessation of exercise. At the first examination the oxygen consumption was still considerably above the resting value three minutes after work had ceased. (Fig. 3.)

FIG. 3.—*Glucose-Tolerance Curves (by Dr. P. O. Ellison).*



Case 2.—Glucose-tolerance tests (glucose meals, 50 g.): (*a*) before, (*b*) after testicle graft, (*c*) four months later. Urine: (*a*) no sugar before test, slight reduction after one hour, no reduction after two hours; (*b*) no sugar before, much sugar one hour after glucose, a trace after another hour; (*c*) no sugar before test, much sugar one hour after glucose, a trace after another hour. F.B.S. = fasting blood-sugar.

CASE 3.—The patient, aged 15¼, was an intelligent healthy-looking boy who complained that he had been rejected for the Air Force owing to his lack of development. On examination he resembled a boy of 12, his height being 4 ft. 11 in. and his weight 6 st. 12 lb. The external genitalia were very small, not larger than those of a boy of 7. The testicles were the size of almonds and very soft to the touch. There was complete absence of hair on the body and the limbs. There were no abnormal deposits of subcutaneous fat on the breasts or elsewhere about the body and nothing of note in the bony development. The condition appeared to be one of delayed puberty possibly resulting from a pituitary defect of the Loraine type. An examination of the mental development carried out by Dr. Miles showed that the patient was distinctly above the average of the ordinary secondary school scholar. In contrast to previous cases sent for examination, he showed an unusual resistance to mental fatigue. The patient's parents were of normal development, but he had a brother who was also juvenile in appearance. Orchitic extracts by the mouth having failed to produce any effect, grafts were employed.

Operation.—On August 27th, 1923, three grafts were inserted in the right tunica vaginalis and at the same time circumcision was carried out on account of phimosis. On examination of the small testicle exposed during operation it was found to be of the variety generally seen in undescended testicle, the epididymis being large relative to the testis and separated from it by a large digital fossa in which a graft was placed. The wound healed by first intention and the patient was discharged on the fourteenth day.

Subsequent History.—He was examined on Nov. 9th, two and a half months after operation; height 5 ft., weight 6 st. 11 lb. No change could be seen beyond the appearance of some very fine hairs upon the pubis. The grafts could still be felt in the upper part of the scrotum. On Dec. 12th, continued growth of fine hair on pubis; height 5 ft., weight 6 st. 13 lb. The patient is still under observation. Although there has only been an increase in height of one inch since the operation, and although the genitalia do not appear to have increased materially in size, the growth of pubic hair is of favourable import.

CASE 4.—Patient, aged 21, was admitted to the Miller Hospital under the care of Mr. Cecil Joll on Feb. 5th, 1923, for symptoms of pituitary tumour, the symptom being persistent headache, vomiting, and failure of vision. Although 21 years of age he had the appearance of a child of 12, and it was stated that he had not grown since that age. Vomiting had started at the age of 13, had no relation to food, and was accompanied by severe occipital headache. During the last six months there had been failure in eyesight, marked loss of flesh, and a great increase in the severity of his symptoms. Examination of the discs showed a condition of "choked disc" with surrounding œdema and small superficial hæmorrhages. Skiagrams negative. Examining the patient from the point of view of the genitalia I found that he had development of a boy of 10. The testes could just be palpated and appeared unusually soft. There was complete absence of hair on the trunk, and only a few fine hairs on the forearm and thigh. There was no prominence of the breasts, and the amount of subcutaneous fat was everywhere below the normal. Although unusually intelligent and alert, the patient appeared to have no sexual knowledge, and never to have shown any interest in the opposite sex.

A diagnosis of the pituitary tumour was made, and in view of the increasing symptoms a decompression operation was carried out on Feb. 8th by Mr. Joll. On the 12th I inserted three grafts into the right vaginal cavity, in order to test their effect on the patient's genital development.

Subsequent History.—Three days after the operation the patient called the house surgeon's attention to the fact that he was experiencing erections for the first time in his life. These continued and appeared to become stronger, but unfortunately the cerebral condition, which had at first been benefited by decompression, again began to cause trouble. A second decompression on the left side was therefore carried out, again with temporary benefit. The patient, however, showed progressive emaciation, and his condition steadily deteriorated until his death on July 20th.

Post Mortem.—The body showed a very severe degree of emaciation. Over the pubis, which previous to the operation had been bare, were some strong dark hairs. On removing the brain a tumour, about the size of a walnut, was found on the upper part of the medulla, spreading upwards into the fourth ventricle, and extending laterally between the pons, medulla, and cerebellum.

Examination of Genitalia.—The scrotum was opened and the testicles removed for examination. The only remains of the grafts that could be found consisted of a small area about a centimetre in diameter in the upper part of the tunica vaginalis. Mr. Geoffrey Keynes's report on his histological examination of this area is appended, as well as the report on the patient's testicle.

Sections of Testis and Testicular Graft.

(1) *Graft.*—The graft appears as a thin layer of tissue lying on the surface of the epididymis. No normal tubules remain in the graft; each appears to be represented by a space containing one or more large structureless cells with peripheral nuclei. No interstitial cells can be seen with Soudan III. Although the testicular tissue appears to have degenerated almost completely, the graft contains several well-formed blood-vessels. The epididymis and vas deferens are normal.

(2) *Testicle.*—The tubules of the testicle are undeveloped. There is no sign of spermatogenesis. No interstitial cells can be seen in paraffin or gelatin sections, though small fat globules are visible among the epithelial cells in a few of the tubules.

Note.—The only positive results obtained by grafting in this case were the onset of erections and the development of pubic hair. The very marked emaciation and the rapid downward course of the patient as the result of his cranial condition were, however, unfavourable factors.

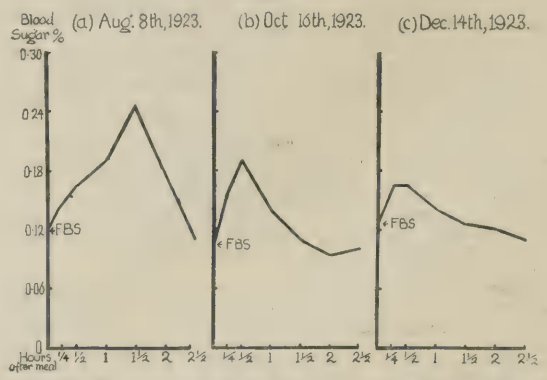
CASE 5.—Patient, aged 39; in August, 1922, had left testicle removed for tuberculosis; in April, 1923, had right testicle and cord removed for recurrence of disease on opposite side. Since the loss of his second testicle he had not been conscious of any marked change either physical or mental. Partial erections occasionally in the morning: no nocturnal emissions. The patient was engaged to be married and presented himself for grafting in the hope that this would allow him to carry through his plans. His only complaint was that erections were rare and transient, and that he was conscious of a very definite loss of muscular energy so that he tired after a comparatively short walk (one mile). Previous to his operations he had walked 12 miles without difficulty. He was not conscious of any mental deterioration, memory and concentration being good, nor had he suffered from depression or other alterations in temperament. Since his operation he had lost a stone in weight. On examination the chief indication of lack of testicular secretion was the absence of hair about the trunk and limbs, except over the pubis, and in the axillæ. However, he still shaved daily, and the hair of the scalp was unaltered. There were no abnormal deposits of subcutaneous fat or development of the breasts. The penis had not appreciably altered in size and the prostate was still palpable.

Operation.—On Sept. 9th, 1923, grafts from the ectopic testis of a man of 38 were employed and were inserted in the following situations: (1) Right tunica vaginalis, (2) left rectus, (3) subperitoneally in the left inguinal region. Convalescence was as usual, except that the patient complained a week later of intense frontal headaches. These were intense for a week and then gradually diminished. Associated with the headaches was a certain degree of

polyuria, as much as 66 oz. being passed per diem. A careful examination failed to discover any cause for the headaches in the eyes, nasal passages, or sinuses, and it is possible that they were pituitary in origin and resulting from the action of the grafts on that gland.

At the end of ten days the headache diminished in intensity, the polyuria ceased, and the patient stated that he felt better. He is still under observation, but has up to the present noted very little change in sexual feeling or in the strength of his erections. However, that the grafts have not been without influence is shown not only by the phenomenon of headaches and polyuria already referred to, but also by the change in the blood-sugar curves.

FIG. 4.



Case 5.—Glucose-tolerance tests (glucose meals, 50 g.): (*a*) before, (*b*) after testicle graft, (*c*) two months later. Urine: (*a*) no sugar before test; no further example could be obtained; (*b*) and (*c*) no sugar before or after taking glucose.

Blood Count (August 3rd, 1923).—R.B.C., 5,300,000 per c.mm.; W.B.C., 7200 per c.mm.; H.C., 94 per cent.; C.I., 0·89; polymorphs, 58 per cent. (4176 per c.mm.); lymphocytes, 32 per cent. (2304 per c.mm.); large mononuclears, 8 per cent. (576 per c.mm.); eosinophils, 2 per cent. (144 per c.mm.); basophils, 0 per cent.; no abnormal cells seen; Wassermann, negative.

General Examination of Urine (Dec. 14th, 1923).—Clear pale yellow urine with a small sediment. Reaction: Acid. Specific gravity: 1018. Albumin: 0·7 per cent. Sugar: Nil. Centrifugalised deposit: A few red blood cells. Fairly numerous white blood cells. Casts in moderate numbers, all hyaline. Some epithelial cells from the urinary tract. (Fig. 4.)

CASE 6.—Patient, aged 58, had had both testicles removed for tuberculosis, the right in November, 1921, the left in January, 1922. Subsequent to castration he put on over a stone in weight. There was also a diminution in the rate of growth of the beard, so that he only required to shave on alternate days, whereas previously he had shaved once or sometimes twice daily. Moreover, the bowels, which had previously been regular, now gave him great trouble, so that he was entirely dependent on purgatives. For two months after operation he had noted erections, but these were now absent. There was complete loss of sexual desire, but occasional nocturnal emissions, unaccompanied by any dream. In temperament he had changed so that he was inclined to be despondent and was without initiative. He complained of hot flushes occurring very frequently and causing him a good deal of distress. These started in the face which became very red, so that other people noticed it. The flush then spread to the rest of his body and he broke out in a profuse perspiration.

Operation.—On Feb. 12th, 1923, an incision was made over the upper part of the scrotum. Considerable difficulty was experienced in finding the vaginal sac, which appeared to have been in great part obliterated, as a result of the previous operation. A bed was made for three grafts on either side, in what appeared to be the remains of the vaginal cavity, and the scrotum was closed in the usual manner.

Course of Case.—For the first three weeks after operation the patient stated that he felt remarkably well, that his appetite had improved, and that he felt much less depressed. He engaged in reading and writing, and said that his hot flushes troubled him very little. A week after the operation he had had an erection. The improvement, however, that was at first noted was not maintained, and when seen two months later the patient had relapsed into his previous condition. On examining the scrotum no remains of the grafts could be felt, and it is almost certain that they had become completely absorbed. The failure in this case was due to the error of persisting in the scrotal operation instead of abandoning the attempt to find a tunica vaginalis and emplanting the grafts, as in Case 5, in the rectus muscle. (Fig. 5.)

	Feb. 8th, 1923.	Feb. 22nd, 1923.
Blood Count:		
R.B.C.	4,960,000	5,840,000
W.B.C.	10,800	12,000
Hæmoglobin	90 per cent.	90 per cent.
C.L.	0·9	0·79
Differential Count:		
Polymorphs	46 per cent.	66·5 per cent.

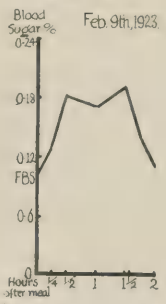
Large mononuclears	4 ,, ,,	3 ,, ,,
Large lymphocytes	4 } 44 per	2·5 } 26·5 per
Small ,,	30 } cent.	24·0 } cent.
Transitionals	3 per cent.	0·5 per cent.
Blood urea	17 mg.	

CASE 7.—The patient, aged 30, was referred to me by Dr. Crichton Miller as a typical case of dementia præcox. He gave no evidence of testicular deficiency, but in view of the work of Mott and others on the degenerative changes occurring in the testes in these cases it was considered justifiable to try the effect of a graft.

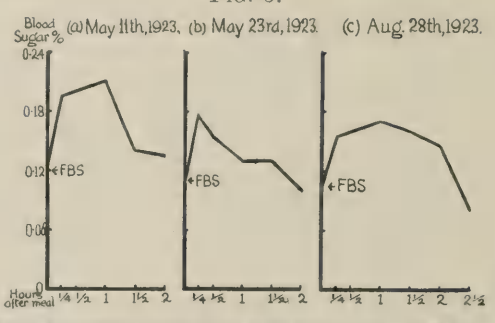
Operation.—Grafts were implanted on May 15th, 1923. The patient was seen two or three times after the operation, but no alteration in his condition, either mental or physical, could be found. Estimation, however, of the blood-sugar curves showed that the grafts had not been without effect on his metabolism. In view of the fact, however, that dementia præcox is associated not only with changes in the testis but also with widespread degenerative processes

FIG. 5.



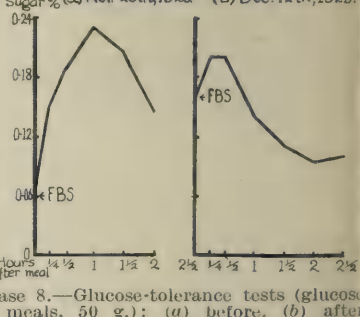
Case 6.—Glucose-tolerance tests (glucose meals, 50 g.). Unfortunately no curves were obtained after operation.

FIG. 6.



Case 7.—Glucose-tolerance tests (glucose meals, 50 g.): (*a*) before, (*b*) after testicle graft, (*c*) three months later.

FIG 7.



Case 8.—Glucose-tolerance tests (glucose meals, 50 g.): (*a*) before, (*b*) after testicle graft.* Urine: (*a*) no sugar before test; no further sample could be obtained; (*b*) no sugar before test; glycosuria present one and a half hours after the meal.

* This patient partook of a fairly substantial meal immediately before the time appointed for his test. It was only possible to keep him fasting for two hours from the beginning of his lunch, as the alternative meant the complete abandonment of the tolerance test. Hence his "fasting" blood-sugar shows a state of hyperglycæmia. It is worthy of note that otherwise the type of response to 50 g. of glucose before and after the testicle graft is identical with that of Case 5.

in the endocrine as well as in the central nervous system, it would be too much to expect that a testicular graft should have any tangible effect in such a condition.

Blood count (May 11th, 1923): R.B.C., 5,200,000; leucocytes, 6800; hæmoglobin, 100 per cent.; colour index, 0·96. Differential count: Polymorphs, 59 per cent.; lymphocytes, 32 per cent.; large mononuclears, 6 per cent.; eosinophils, 3 per cent.; basophils, 2 per cent. (Fig. 6.)

CASE 8.—Patient, aged 45, referred to me by Colone L. W. Harrison for impotence. The patient stated that he had occasional erections in the morning, but that they were transient in character. Sex desire was present though feeble. There were no obvious signs of testicular deficiency. He shaved daily, showed well-marked hair development, and normal development of the genitalia. He had been treated for syphilis and the right testis was indurated and shrunken.

Operation.—On Nov. 20th, 1923, six grafts were implanted within the scrotum. On Dec. 7th the patient stated that he had several strong and more prolonged erections. As he had to leave for Canada, no further opportunity occurred for examining him. (Fig. 7.)

CASES 9 and 10.—In both of these cases grafts were implanted for senility during the course of an operation for prostatectomy. Case 9 made an excellent recovery and left the hospital in a greatly improved state of health. As, however, most of this could be accounted for by the beneficial results of prostatectomy, it is impossible to say to what extent the testicular grafts had any effect. Case 10 was a feeble old man with marked kyphosis, bronchitis, and cardiac trouble, who died three weeks after enucleation, of pulmonary complications. During the first part of his convalescence he had made good progress, and on his death his relations (who knew nothing of the insertion of the graft) deplored to the house surgeon the misfortune of his death as he had been so well after his operation, and, what was so remarkable, the hair on his head had begun to grow again!

At the autopsy I examined the grafts that had been inserted. The operation had not been an aseptic one and there was evidence of suppuration. A microscopic examination of the grafts showed necrosis, more marked towards the centre of the graft. It is probable that the temporary improvement in his condition and the growth of hair were due to absorption of hormone, even although necrosis had occurred.

INFLUENCE OF THE GRAFTS ON THE GLUCOSE-TOLERANCE CURVES.

For the following description of the method of examining the patients, and for his comments on the changes observed in the glucose-tolerance curves after operation, I am indebted to Dr. P. O. Ellison.

"The method of blood-sugar estimation devised by Prof. H. MacLean has been used throughout. After a fast of three hours, a sample of blood was taken from the patient, who was immediately given a dose of 50 g. of glucose in 150 c.cm. of water. Further samples of blood were taken at intervals up to a period of two or two and a half hours. The amount of sugar in each sample was estimated, and a curve plotted from the results.

"The first curve in each series was made a few days before the operation; the second curve between two and three weeks after operation, to gauge the immediate effect of the absorption of testicular substance, allowing an interval for any possible inflammatory change to subside; the third after a further interval of from two to three months.

"In each case a definite change in the response to 50 g. of glucose has been found in the curve taken shortly after the graft. It might be expected that any modification that occurred would be of the same nature. The response of one patient, however, differs in a very striking manner from all the others (Case 2).

"In three of the patients, in the test taken before operation, the blood-sugar does not reach its maximum until one and a half, one, and one hour respectively. The maximums were unusually high—0·23, 0·25, and 0·21. The blood-sugar had diminished to approximately normal values within two to two and a half hours. These curves, therefore, show that the patients had a definite diminution of sugar-tolerance. The curve taken two to three weeks *after* operation shows that the blood-sugar reaches its maximum height within half an hour and has returned to normal value in an hour; the sugar-tolerance was therefore normal.

"Case 2 presents different features, for here the blood-sugar concentration half an hour after a dose of 50 g. of glucose is much higher (0·26) than before the graft, and it is accompanied by a pronounced glycosuria. The case is, however, complicated by the fact that he presents features of pituitary disease and the blood-sugar tracing resembles in some degree the curve described by MacLean under the name of 'lag' curve. Another test, repeated after an interval of three months, gives identical results.

"Taking these four cases into consideration, it seems reasonable to conclude that a definite effect has been produced on the mechanism of carbohydrate metabolism of patients who have been subjected to the operation of testicle grafting. In two of them the effect produced seems to be wearing off a little, but in the third the effect is maintained up to date. The natural assumption is that the change is due to the absorption of testicular hormone. The maximum effect is produced shortly after the implantation of the graft. It may be that a successful testicle graft, yielding testicular hormone, will cause a permanent alteration in the type of response to the ingestion of a certain amount of carbohydrate; and that a reversion to the former type of curve would mean absorption of the graft. In any case it is not desirable to attempt to interpret these changes any further, and it is best to keep an open mind on their significance until further cases and prolonged observation give us sufficient data to make our deductions."

THE LIMITATIONS OF THE TREATMENT OF TESTICULAR DEFICIENCY BY MEANS OF GRAFTS.

Although the results obtained from the treatment of testicular deficiency by means of grafts are distinctly promising, it must be remembered that there exist limitations to the use of the method quite apart from those imposed by the difficulty of obtaining material. In very few of the cases that present themselves for treatment with signs of testicular deficiency is the deficiency entirely confined to the testicle. In other words, we are seldom called upon to treat a frank state of hyper- or hypo-secretion of the testis. Especially is this true of those cases of congenital deficiency that are the result of some general pathological process taking place early in life. In such cases, even although only one gland may originally have been at fault, as the result of its failure other members of the endocrine group in time become affected. Tiernay has laid special emphasis on the importance of this reciprocal involvement of other glands, in a recent paper on the subject of pituitary disorders, and what is true of pituitary deficiencies is equally true of disorders of the testicular secretion. I cannot do better, therefore, than reproduce his own words on the subject: "We have found that many of the pituitary insufficiencies have been in their early stages apparently uniglandular and that after a variable length of time, usually a year, there almost constantly occurs a secondary reciprocal involvement of the thyroid and gonads. We have also found that after a reciprocal involvement, the diagnosis of which is based upon associated hormonic signs, there is less likelihood of sufficient response to therapy either single or compound."

An excellent example of this reciprocal involvement of other glands of internal secretion is furnished by No. 2 of the cases reported. In this case atrophy of the testis had been followed by involvement of the pituitary, so that the clinical picture was that of testicular deficiency associated with hypo-pituitarism rather than that of testicular insufficiency alone. For this reason the results obtained from a testicular transplant were limited and did not effect complete disappearance of symptoms. The same observations apply with even greater force to Cases 3 and 4, in which the pituitary gland was in all probability primarily at fault and the gonads only secondarily involved. To obtain the best results in these cases grafting should be combined with the use of extracts of the other glands involved.

Duration of Grafts.

A further question of the greatest importance in assessing the value of grafts in the treatment of testicular insufficiency is the question of their durability. Will a hetero-graft of testicular tissue that has been successfully vascularised survive indefinitely, or will it undergo slow absorption? To this question I am unable to give a positive answer based on my own work, as none of my operation cases are of sufficiently long standing to allow of deductions being made. Voronoff has stated that in one of his successful cases the improvement has been maintained for a period of four years, and he is not inclined to place a limit on the life of a graft. Personally I believe

that a hetero-graft, however complete its vascularisation may be, undergoes from the very beginning a process of absorption. I have arrived at this conclusion partly from a consideration of the behaviour of hetero-grafts in general, and partly from observations of my own cases. The time taken for a graft to become absorbed must, of course, vary in different cases, but I am inclined to think that a life of two years is the utmost that can be expected. This does not, of course, necessarily mean that at the end of that time the patient will relapse into the state in which he existed previous to his operation. Morris made the interesting observation that in one of his cases who possessed testicles, although atrophied ones, the insertion of a graft stimulated the growth of the patient's own testes, and that this enlargement was maintained even after the grafts were no longer palpable. A somewhat similar action may possibly be exerted on other endocrine tissue and the impetus given by the graft thus outlast its life. The probability, therefore, that grafts will in time become absorbed is not a valid argument against their use. It may, for instance, be possible by means of a transplant to assist a boy showing signs of eunuchoidism through the period of puberty, even although later the grafts may disappear. Lydston, who has been a pioneer in this work, has written in no undecided manner on the very topic: "It is my belief that practically all, if not all, subjects, if operated on at or about the usual age of puberty can be taken through puberty and will show sex development with corresponding secondary masculine sex characteristics approximating the normal more or less closely." I am in entire agreement with Lydston in this, provided the case be one of pure testicular deficiency and not one of hypo-pituitarism.

THE RÔLE OF THE MUCOUS MEMBRANE IN DISEASES OF NOSE, THROAT, AND EAR.*

BY W. STUART-LOW, F.R.C.S. ENG.,
CONSULTING SURGEON, CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.

COMPARING and contrasting the skin proper with the mucous membranes, or, as I should say, the inner skin, one cannot help being struck with the great attention that has always been and is still being paid to the skin; it has a history and a literature, and societies and journals devoted to its study. Investigation and research have made the skin a favourite field for work, whereas the mucous membrane or inner skin has suffered comparative neglect as regards systematic study as an organ and a system in the animal economy; and yet the part played by this inner skin is of paramount importance and far exceeds that of the skin proper as a body protector and preserver against the inroads of disease. For the functional activity of the mucous membrane it is indispensable that the surface should constantly maintain its natural moisture, and for this purpose a mucous secretion is continually being poured over it. Mucus is not the simple solution that we are apt to consider it, but is of very complex composition and extraordinary function. Its composition has not yet been elucidated. We know that it contains a protein radical and glucosamin—the nitrogen-containing carbohydrate of mucin, a non-fermentable sugar. This carbohydrate group is very rich in oxygen. Mucin also contains a very large amount of sulphur. It has now been proved that mucin with its wonderful chemical composition has a barrier action against the entrance of toxic ferments and bacteria into the system, and this in virtue of the fact that the nitrogen-containing carbohydrate is not fermentable, and is not affected by the oxidising and dissociating ferments of mammals. Mucin is also highly resistive to putrefaction, and it was affirmed by Cohnheim that "the peculiar physiological property of mucin makes the entrance of putrefactive bacteria a difficult matter, while the bactericidal properties also play a part.

One of the curious facts of pathology is that certain bacteria actually secrete a true mucin for their own protection against the attack of other bacteria. Mucin belongs to the amido group; its exact stereochemical position, being very intricate, has not yet been fully worked out. It is very rich in oxygen, however, and it is known that this oxygen is very loosely attached and can be, and is, readily parted with, and that it is in such a manner that enzymes (ferments) given off by virulent bacteria are destroyed and the body protected from their insidious and destructive ravages. The wide range and high value of mucin are therefore evident.

STRUCTURE AND FUNCTIONS OF MUCUS.

The structure of mucus in its singular complexity is enough in itself to support the belief that its functions are more intimate and subtle than that of a mere lubricant. The moist and sticky surface of the mucous membrane catches up the innumerable particles of dirt and bacteria that enter with the inhaled air. In order to carry out these purposes it is armed with two mechanisms of great value—one the secretion, mucus, of which we have just given a description, and the other the ciliary action of the mucous membrane. Once a stationary state becomes established, the bacteria and their toxins are likely to penetrate to the epithelial cells, and, by a solution of them through the production of enzymes—ferments—pass into the circulation. There is now experimental proof that in the "carrier" state when the body is protected from the onset of various pathogenic organisms it is the mucus surrounding the bacteria that restrains their virulence. This protection is not a real immunity in the essential meaning of the term, for its subjects often suffer an infection at a later date when the protective mucous barrier has gone. This explains why the deadly meningococcus and the deceptive diphtheria germ can rest in the naso-pharynx, throat, and nose, their host remaining immune meanwhile, but may be readily transmitted to another person not equally protected. The virulently-toxic Shiga's bacillus, in the same manner, can be lodged in the system for a long time without giving rise to toxic symptoms.

It is now 22 years since I first drew attention to the value of mucin as a therapeutical agent in two papers published in THE LANCET,[1] and research since that time has fully borne out its great usefulness.

THE EAR FROM THE ENTRANCE TO THE EUSTACHIAN TUBE UPWARDS.

In considering the mucous membrane and the part it plays in diseases affecting the various regions, we will first take that tract running from the pharyngeal end of the Eustachian tube up through the middle ear and on to the apex of the mastoid. The Eustachian tube and the tympanic cavity are lined by a common mucous membrane with a ciliated epithelium. The mucous membrane varies in its consistency, in the number of mucous glands and lymphatics, and in the kind of epithelium. From the lowest part of the Eustachian tube, where the mucous membrane is thick, it gradually becomes thinner and thinner right over the tympanic cavity through the aditus to the

* Abstract of an address delivered at the Central London Throat, Nose, and Ear Hospital.

[1] THE LANCET, 1901, ii., 972; 1902, i., 961.

lowest mastoid cells, where it is a muco-periosteum and contains neither mucous glands nor cilia. On the inner side of the membrana tympani it is a very thin delicate layer covered with squamous epithelium. The epithelium on the ossicle and tensor tympani and stapedius muscles is not ciliated. There are few mucous glands in the tympanic cavity, but throughout there is a distinct development of the lymphatic layer. At the pharyngeal end of the Eustachian tube, where it bulges into the pharynx, and for a third of its length upwards, there is a marked development of the mucous membrane; the latter is thick and vascular, and the lymphatics and mucous glands are well developed and numerous. At this part these structures constitute a veritable lymphatic gland surrounding the tube, and this acts as a guard to the entrance, effectually stopping, destroying, and carrying away any septic organisms that might try to work their way into the tympanic cavity from the naso-pharynx. Over the foramen rotundum the mucous lining is very delicate, as is the fibrous membrane that closes this opening, so much so that in life it is transparent, a thick mucous membrane would not aid the transmission of sound. At the entrance to the aditus there is a special fold of mucous membrane which practically makes the tympanum and the antrum independent cavities. This is often so well developed that mastoiditis may be present without otitis, or, as oftener happens, otitis without mastoiditis. The fact that the mucous lining of the antrum and mastoid cells is so thin as to constitute a muco-periosteum containing no mucous glands and having but very little underlying lymphatic layer explains what is familiar to us all—the rapid way in which sepsis can, and often does, spread in this region. In my experience, such cases of rapidly spreading sepsis with bone caries are most often met with in young adults. There may be an extraordinary degree of absorption of bone in the mastoid, especially of its inner shell, so that the whole process forms a single cavity bounded by dura mater and lateral sinus on the upper, inner, and posterior sides, while the outer wall resists perforation till late. Perforation (Bezold's) into the digastric fossa is common. In spite of this extensive destruction the temperature is usually normal, or but slightly raised. Peri-sinous abscess is very common, or the sinus may form part of the boundaries of a single large cavity. In one of my cases—a man of 40—the abscess within the mastoid communicated with a large peri-sinous abscess.

The sea of lymph in the submucous lymphatics of the middle ear and Eustachian tube doubtless communicates with the parilymph and endolymph, and in this way helps to maintain the tension in these situations, so essential for hearing and equilibration. The dragging action of the tensor tympani and stapedius muscles doubtless helps to pump this lymph on its course. Is it not likely that the connexion that has been shown to exist between middle and internal ear deafness has here an explanation? In otosclerosis, chronic catarrh of the middle ear, and chronic suppuration of the middle ear (residual) it is now found that there is an impairment of the labyrinthine function. This may be because through disturbance or cessation of this lymphatic circulation the tension in the perilymphatic and endolymphatic channels is impaired, and, therefore, the chance of the specialised epithelium in the organ of Corti, maculæ, and cristæ interpreting the vibrations of the waves of pressure is diminished. There can be little doubt that nearly all affections of the ear (especially now that nerve deafness is known to be largely influenced by middle-ear conditions) result from sepsis introduced from below and passing upwards into the Eustachian tube from a septic pharynx—a failure of the mucous and lymphatic structures, stationed at the lower end of the Eustachian tube, to protect the vulnerable middle ear.

After many years' experience I have come to the conclusion that chronic catarrh of the middle ear—that bugbear of otology—is a consequence of insidious sepsis, let into the tympanic cavity in this manner. This would cause irritation, for septic organisms and their products are exceedingly irritating to delicate mucous linings, especially if their virulence is not restrained by the presence of mucous secretion. These infections would also result not only in irritation and congestion of the mucous lining of the middle ear, but in desquamation of the superficial epithelial covering, ending in atrophy. It has often impressed itself upon me that even oto-sclerosis must be a consequence of sepsis. Once the mucous and lymphatic structures at the lower end of the Eustachian tubes are rendered useless, the passage is open, and tension not only in the middle ear, but also in the labyrinth, is reduced; nutrition of their structure is so altered that impairment and fixation follow.

NOSE AND NASO-PHARYNX.

In the nose and naso-pharynx the epithelial covering is everywhere ciliated except in the olfactory region proper, in the upper third of the nasal cavity. The lymphatic layer is also well developed throughout, and there is a great accession of it on the posterior wall of the naso-pharynx where adenoids accumulate. The lymphatic layer of the mucous membrane is also particularly well marked in the inferior turbinals, especially in the posterior half and on the posterior part of the nasal septum, in which situation mucous glands are specially abundant. The special functions of the mucus are pre-eminently displayed in the nose, where, being sticky, the mucus traps foreign bodies, dust, &c., and bacteria, entangles them, destroys them, dissolves them, and holds them till the phagocytes can come along and consume them. An efficient mucous membrane, then, lets nothing pass; and, if it did, whatever escapes would be blown upon the posterior wall of the naso-pharynx, and there caught in the same way as in the nose through which it had escaped.

Paget's investigations on the production of antibodies by the nasal mucous membrane which leads to destruction or neutralisation of the toxins of the tubercle bacillus are very remarkable, and well emphasise the high value of nose breathing in the prevention of respiratory diseases and the bactericidal properties of the secretions of the upper respiratory tract. Swabs taken from the nasal passages of students and nurses in consumptive wards are often found to contain tubercle bacilli, but tuberculosis of the nasal passages is quite rare. It is evident, therefore, that in the upper respiratory passage there is a bactericide capable of destroying these bacteria.

The mucous membrane of the nose is in one respect very different from that of the ear, in that it contains erectile tissue. The latter is absent in the Eustachian tube and tympanum; and just as much of our work in the ear results from the mucous lining being so thin, so also much of our work in the nose directly follows from the lining being thick and erectile, and thereby causing nasal obstruction, a very serious handicap in the fight against sepsis.

I should like to say a word about rhinitis sicca and nasal mucous polypi—two conditions frequently in our hands for treatment, and very common.

Rhinitis Sicca.—Rhinitis sicca—so called for want of a better name—or, as I should call it, hypomyxia-naso-pharyngia, the deficient secretion of mucus. This is, I think, much the commonest deviation from health of the nasal mucous membrane. The condition of the anterior half of the inferior turbinal is the criterion of the normal mucous membrane, and in health appears rosy-red, rotund, resilient, and moist. In rhinitis sicca it is pale, desiccated, crusty, and cobwebby—that is, strands of dry mucus pass from the septum to the turbinal. The rest of the nasal lining is more or less dry and crusty. This dry, and therefore functionless, condition of the mucous membrane of the nose frequently results in serious deterioration of health, since bacteria-laden dust is freely inhaled, passing unfiltered down into the lungs, and is a common precedent of tuberculosis. Moreover, normally over a pint of healthy mucus should pass down through the naso-pharynx to the œsophagus daily. In the absence of this these parts become desiccated,

with consequences which if prolonged over a lengthy period are many and varied, and always deteriorative. It is now recognised that man is becoming less and less hirsute. Nature seems to have anticipated that man would, in his multifarious occupations, be liable to have to respire all sorts of impure and bacteria-laden air; to combat the dangers incident to this respiration the nose is supplied with a most complete and efficient protective apparatus in the shape of the short stiff hairs lining the entrance of the nose. These hairs catch and hold dust and all debris from the air; and, after having been temporarily arrested, this debris is readily blown out again. Should such aerial flotsam and jetsam pass this air filter and be drawn, with the inspired air, into the middle chambers it would then be arrested and held by the mucous coating on the lining; and, most likely causing irritation, be violently expelled by setting up sneezing. This is how sneezing is beneficial, becoming a valuable protection by forcibly throwing out foreign material from the nose. Loss of hair on the external skin may be a matter of indifference to the human race, since we can readily replace its function by wearing extra clothing; but in the case of the nasal entrance, loss of hairy protection is a serious defect, enabling microbes freely to enter the nasal cavities—freedom of access which lays the body more readily open to bacterial attack. It is no less certain, however, that man, and especially woman, is rapidly becoming less and less mucose. Rhinitis sicca, or hypomyxia-naso-pharyngia, is becoming common. This means a dry nasal interior, the secretion from the nose being thin and watery—serous. In the absence of the sticky normal mucus the bacteria-trapping function of the nasal lining is lost, and its protection against inhaled particles diminished. The pint of mucous secretion that should be produced daily in the nasal spaces is in abeyance, and the moistening, protecting, and cleansing process that goes on through the passage of this amount of mucous discharge down over the naso-pharynx, oro-pharynx, laryngo-pharynx, and œsophagus ceases; thus these surfaces are exposed to irritation and become congested and inflamed, and malignant disease is likely also to arise as a result of prolonged epithelial irritation.

Nasal Mucous Polypi.—It is very noticeable that nasal mucous polypi always spring from the region of the middle turbinal or higher up, but never from the inferior turbinal. I have often told the students in my clinic that I would give £20 to anyone showing me a mucous polypus arising from the inferior turbinal. I think this immunity from polypi is due to two conditions—first, that the mucous covering on the inferior turbinals is much thicker and has many more mucous glands on it, being thus much less likely to become dry than the thinner lining of the middle turbinal; and secondly, because we inhale through the middle meatus, which is dried and irritated by the impact of the dust-laden inhaled air. The statement that there is always sepsis—even caries of the bone—at the spot from which the polypus springs I cannot accept. Again, we exhale through the inferior meatus, and the expired air saturated with water is constantly preventing the inferior turbinal from getting too dry, so dry that a mucous polypus might spring from it if irritation from dust, &c., were present. I am told by a friend who has travelled much in Russia that mucous polypi are very common in that country, almost every second person being affected. This is no doubt largely accounted for by the very sandy, dusty atmosphere, and the warm, dry, and impure air of the living rooms. Russia, when she has recovered from her present distressful state, is doubtless the field for our rising generation of naso-pharyngeal specialists.

The amount of dirt in the London atmosphere that the nose has to deal with and prevent from getting into the lungs is enormous. It is a fact that 5 million tons of coal are consumed in London annually for domestic purposes alone. It is calculated that as much as 90 tons of soot is a common quantity to be floating over London, and that when the wind is in the north dust is wafted down to us even from the Midlands. If we could roll away the clouds of smoke which daily hang over the homes of our people, we should by the same action make exiles and fugitives of many of our deadliest foes. It has been possible to create a smokeless New York, even a smokeless Essen. That London and other of our cities remain under this curse is proof only of our backwardness in making use of the knowledge which is now at our disposal. It will be agreed, I think, that the nose with a normal mucous lining is one of the chief gateways of health and happiness, and on its proper function depends both physical and mental efficiency.

MOUTH AND ORO-PHARYNX.

The mucous membrane of the mouth and oro-pharynx is covered with squamous epithelium thicker in some parts than in others, having in it comparatively few mucous glands, and those very minute. On the gums there are none; there are none on the dorsum of the tongue, none on the back of the pharynx; but there are mucous glands on the sides. The cavity of the mouth is largely dependent for its moisture and mucus on the efficient action of the salivary glands; and the oro-pharynx for its mucous coating and lubrication depends upon discharge coming down from the naso-pharynx. Dr. Sim Wallace was the first to emphasise the great value of mucus as an antiseptic and preventive of dental caries. Physicians have always laid great stress on the importance of looking at the tongue as a criterion of the proper performance of the gastric function. We have, as medical students, been schooled on this point, and the public expect the tongue to be looked at; it is a tradition, to neglect which would jeopardise a reputation for wisdom and carefulness. I think, however, that it would be much more helpful to look past the tongue at the posterior wall of the oro-pharynx and observe its coating, moisture, or dryness as an indication of the normal amount and quality of mucous secretion passing down from the naso-pharynx. If this surface is seen to be desiccated the stomach and œsophagus are not receiving an adequate amount of mucus to supplement their own supply, and should there be streaks of mucus adhering to the oro-pharyngeal posterior wall, it can be taken as a sure indication of a pathological change in the mucus-secreting function. Whether the tongue is clean or not is largely determined by the nature and consistency of the food and the amount of the salivary secretion. If the food is firm or hard, the attrition of the lingual dorsum on the surface of the palate keeps it clear of superfluous and deciduous epithelium, and so, what is called "clean." For a healthy, clean, aseptic mouth the chief requirements, therefore, are attrition, friction of the tongue, teeth, gums, and palate; and an abundant salivary secretion, one of the principal constituents of which is mucus, both as a lubricant and as a restrainer of sepsis. I consider that we do not realise sufficiently the value of saliva as the main antiseptic of the mouth and oro-pharynx. And it is also the chief lubricant and protection of the mucous lining.

The sublingual glands are entirely given up to the secretion of a mucous saliva. The submaxillary glands are principally mucus-secreting, although partially serous, while the parotid gland is entirely serous, secreting no mucus. Quarts of saliva are poured out into the mouth in the course of a day, and the total quantity of mucus thus secreted is very large.

In severe oral ulceration, ulcerative and necrotic stomatitis, Vincent's angina, and other intractable ulcerations of the mouth, it has been found very difficult to modify the bacterial flora by intensive treatment. This is due to the fact that the organisms found in the mouth have extended into its superficial layers, into crevices between the epithelial cells, and into the orifices of the mucous glands. These bacteria are very firmly lodged in the tissues, and chemicals applied to the mucous surfaces cannot effect sterilisation without also destroying the superficial layers of epithelium at the same time. The lymphatic layer of the mucous membrane is distinct in the mouth, although thin in the oro-pharynx, especially on the

posterior wall; but there are accumulations in places, emphatically so in the lingual and faucial tonsils. Both of these are simply a great thickening and heaping up of the lymphatic layers of the mucous membrane in the two situations. Over the tonsil the mucous membrane is very thin, being only a single layer of flattened cells; there are no mucous glands on the surface, and few on the tonsillar crypts. In both regions phagocytosis is very active, and the fact that the mucous covering is thin on the tonsil probably favours it. It is quite likely that pyorrhœa alveolaris is coincident with a shortage of salivary secretion, especially the more concentrated and viscid secretion of the sublingual and submaxillary glands. Pyorrhœa alveolaris is now considered by Goadby to be primarily a disease of the gums, owing to irritation and infection of the gum tissues around the necks of the teeth, and beginning with a mild but chronic infection of the gingival margin. I have recently observed two cases of salivary calculus in elderly people, when the mouth was very foul and there was much tartar on the teeth. The mouth in both was frequently very dry. It is safe to say that the salivary secretion was reduced; and it is not at all unlikely that this, and all the trouble (including the evident pyorrhœa) was due to salivary shortage.

In xerostoma, met with more commonly in women, where the mouth is dry and leathery and there is a great shortage of the salivary flow, the teeth are so affected that they crumble and fall out. This emphasises the invaluable rôle of the saliva, and especially the abundant mucin contained in it in the maintenance of oral hygiene. I think it is to be regretted that sialogogues have now largely gone out of fashion in our prescriptions; some of these I have found very useful, such as small doses of copper salts—ordering stout to be taken suffices as a sialogogue, as stout contains a small amount of copper salts. Jaborandi, and small doses of mercury, and potassium iodide, of course, are effective mouth-moisteners. Lobelia I have found useful in augmenting the salivary flow, and the sulphate in small doses often acts beneficially in asthma. This may be by modifying, and most likely augmenting, the mucous secretions which are lessened and perverted in this distressing affection.

THE CANCER PROBLEM.

Since three-quarters of all malignant disease arises on epithelial-covered surfaces, it is appropriate that a consideration of it should now command our attention. As before mentioned when discussing histological physiology of mucous membranes, everywhere in the healthy body there is found a separating material between the cells. Even the most closely approximated cells, such as the squamous cells on the surface of the vocal cords, are separated by intercellular cement material. Compare this state of things with the cells in an epithelioma. Here there is no separating substance whatever, but these cancer cells lie close together, and in the cell nests they are very firmly packed. Now this is a very striking contrast, and it is not at all unlikely that the rubbing shoulders, so to speak, of those cells sets up such a disturbance of the metabolism as to account for subsequent rapid division. Such cells have been said to be embryonic (rapidly dividing growing from within) and so the cancerous cell is supposed to have taken on the characteristics of the embryonic cell, and cancer is said to be a reversion to the embryonic condition. Certainly, the more the cancer cells resemble the embryonic cells, the more rapid the progress of their growth. In the ovum the cells divide with great rapidity after fertilisation has taken place. Symmetrical division goes on again and again until a mulberry-like mass of cells is formed—the morula. In this way arises a collection of small cells with no intercellular material whatever. A cavity soon appears in the morula, and the blastula is constituted—the cells now arranging themselves around the periphery and a group of cells forms at one pole, many of which are more irregular than those around the periphery. All are very rapidly dividing and soon become arranged in three layers—the ectoderm, the endoderm, and the mesoderm—constituting the blastoderm. The essential lesion of carcinoma is the penetration of cells into the surrounding tissues, but whether this new departure on the part of the cells is a result of a cellular change or of some alteration in the intercellular-resisting substance is not yet clear.

The probability is that there is a certain degree of both. In old age the intercellular material undergoes a wasting change, and as a result of this its resistive power against the ingrowth of epithelial cells is lessened and thus the onset of carcinoma is favoured, particularly as the overlying epithelium remains much longer active and thus there is an influence inducing the cells to penetrate inwards among the tissues. The centrosome, in cells on epithelial mucous surfaces, occupies that part of the cell nearest the surface and, therefore, the part most exposed to injury and irritation. The centrosome is the dynamic centre and plays the leading part in the division of the nucleus, the proliferation of the cell, and the regulation of movement.

Now, I believe that there is a long antecedent or precancerous stage in the development of cancer, and that during this time what occurs is a gradual removal of the intercellular cement material, and so bringing the cells themselves closer and closer together until they finally touch—juxtapose—and that this results in a friction or disturbance, and an irritation ending in a rapid cell division.

Perhaps the processes of irritation, such as occurs from paraffin and tar, which have resulted in the artificial production of cancer in mice and rats, act in such a way. In support of this contention, it is remarkable to note that cancer most often arises in regions where the epithelial cells are naturally surrounded most scantily by intercellular material—viz., on the skin surface, on the vocal chords, on the surface of the palate and its pillars, on the lips, &c., and in the breast.

It may be that two factors work towards the preparation of the tissues for the actual start of the carcinogenous change in any region, as I am persuaded from long years of study of cancer—first, gradual and continuous deterioration of health during which time the intercellular cement material, tissue-mucus, is absorbed or wasted; and secondly, a local change, most probably an irritant. That the cancerous growth is the result of some long-continued irritation is the oldest theory of all. The local production of cancer in mice and rats is a distinct advance. Researches on rats, in setting up the cancerous change on the squamous-celled surface of the stomach in the cardiac region are important, and prove that a surface covered with squamous cells is most susceptible, or, in other words, least resistant. This, I think, is due to the scanty intercellular material found in squamous covered surfaces. A new light was shed on cancer research when Johannes Fibiger, of Copenhagen, carried out his brilliant work on the production of gastric cancer in rats, showing that cancer was capable of being produced experimentally. In the sugar refineries of Copenhagen both cockroaches and rats swarm, and the rats eating the cockroaches developed a tumour in the cardiac end of the stomach (in this animal, covered with a squamous epithelium) which proved to be an epithelioma. The explanation of this result is that the larvæ of a nematode worm (thread-worm) pass a stage of development in the muscles of the cockroach, and this swallowed by the rat becomes fully developed in the squamous epithelium of the cardiac end of the stomach, thereby producing an epithelioma. Much has been done in the way of laboratory research, but experiment on animals, while helpful, is not going to induce us to lessen the intensity and incisiveness of our clinical work. I am very hopeful that much may yet be accomplished in our own specialty. We are warranted in such expectancy from the frequency with which the malady occurs in the throat, and the unique opportunity thus given us for clinical study.

A SIMPLE METHOD FOR THE PREPARATION OF INSULIN BY AQUEOUS EXTRACTION.

A Preliminary Communication

BY E. C. DODDS, M.B., B.S., B.SC. LOND., M.R.C.S.,
CHEMICAL PATHOLOGIST TO THE MIDDLESEX HOSPITAL, AND LECTURER IN BIOCHEMISTRY, UNIVERSITY OF LONDON;
AND
F. DICKENS, B.A. CANTAB., PH.D. LOND., A.I.C., D.I.C.,
ASSISTANT IN BIOCHEMISTRY DEPARTMENT, MIDDLESEX HOSPITAL.

(From the Biochemical Department of the Bland-Sutton Institute of Pathology, Middlesex Hospital.)

THE investigations about to be described were undertaken with a view to determining whether any simplification could be effected in the method now in general use for the preparation of insulin. The method of Collip,[1] as modified by Dudley,[2] gives very satisfactory yields, but is admittedly expensive both from the point of view of alcohol and labour. For a five kilo batch of pancreas 13·5 litres of 95 per cent. alcohol, and 3 litres of absolute alcohol are required, whilst from the point of view of labour the supervision of an expert is required for practically the whole of the process which takes, on an average, about eight days.

In the first experiments of Banting and Best [3] water was used as an extracting fluid, but the yields were poor, owing to the unchecked action of destructive enzymes. After careful experiments alcohol was substituted for water, since it inhibited tryptic action, and at the same time extracted the active principle. From these experiments the method of Collip was elaborated. In a recent paper of Best and Scott [4] these writers refer to attempts at a more economical water extraction process, but out of 150 experiments made by them their best yields only amounted to a quarter of that obtained by their alcohol process. Perhaps the poor results can be attributed to prolonged exposure to tryptic action during the filtrations which, we have found, present many difficulties. Allen, Piper, Kimball, and Murlin [5] published a rapid method of insulin extraction using 1/5 N HCl as an extractor. They do not state their yields, however. We have tried this method but with little success.

Reduction of Tryptic Action: Separation of Insulin from Pancreatic Proteins.

Remembering that insulin is freely soluble in water and that this fluid forms its natural medium, we thought it highly probable that aqueous extraction would really be the ideal method, provided that tryptic action could be reduced to a minimum. In order that a water extraction process may give a satisfactory yield, the following points are essential. Firstly, reduction of tryptic action to a minimum; and secondly, efficient separation of insulin from the pancreatic proteins.

The first difficulty can be overcome by reducing the time of extraction to a minimum consistent with thorough extraction, and at the same time employing some inhibitory substance in the extracting fluid. Collip had suggested that formic acid was advantageous, hence it was thought that its addition to the extracting fluid would help in the inhibition of tryptic action. The second question regarding selective separation of insulin from the relatively enormous quantity of protein associated with it presents much greater difficulties.

The solution to this problem was indicated by the results of some experiments carried out in these laboratories on the relative solubility of insulin and protein picrates in organic solvents. Dudley [2] had previously shown that insulin picrate is highly insoluble in water. It was therefore a matter of great interest when we found that whilst the picrates of most proteins are sparingly soluble in moist acetone or alcohol, insulin picrate dissolves in these solvents with unusual readiness.* This fact overcomes the difficulty of separating insulin picrate in a highly concentrated form from the bulk of extraneous protein picrates precipitated with it; whilst Dudley's purification method provides the key to the regeneration of its hydrochloride from insulin picrate.

Experiments were at once commenced with a view to determining whether this could not be made the basis of a new process. Outlined briefly, the method consists of extracting the pancreas with aqueous chilled formic acid, and precipitating all the proteins from the fluid residue by the addition of saturated aqueous picric acid. The precipitate is filtered off and the moist picrates are extracted with acetone, thus dissolving out the insulin picrate. The acetone solution is filtered off, and the contained picrate precipitated by dilution with water and picric acid. This crude insulin picrate is filtered off and dissolved in acid alcohol after the method of Dudley, and, on dilution with acetone, the hydrochloride separates.

Technique of Method.

After many experiments and trials, the following method has been found to yield satisfactory results.

First Day.—Freshly collected pancreas is dissected to remove fat and extraneous tissue and weighed. The following description applies to a 5 kg. batch.

The pancreas is minced into 2·5 litres of 1 per cent. aqueous formic acid, which has been previously chilled to about −3° C. The mixture is well stirred at intervals, and allowed to stand for 10 to 20 minutes, after which it is poured on to a fine sieve, and as much liquid as possible is pressed out by hand. The fluid is received into an equal volume of saturated aqueous picric acid solution. The solid material retained by the sieve is pressed in "jean" and the expressed liquid added to the picric acid mixture. The solid material is removed from the press and is reminced into a further 2·5 litres of chilled formic acid solution, and the above process repeated, using a further quantity of the picric acid solution. This procedure is repeated a third time, giving in all a total volume of about 15 litres of the picric acid mixture. After the mixture has been well stirred and allowed to stand for ten minutes a portion is removed and filtered through a small folded filter and the clear filtrate tested for complete precipitation by the addition of more picric acid solution. Should a precipitate form, more picric is added to the main bulk. The precipitated picrates are then collected by filtration.

We have found the most rapid method to be preliminary filtration through folded Chardin filter papers, from which the wet precipitate is transferred to Buchner funnels. The total time taken by this procedure should not exceed two hours. The moist picrates are extracted two or three times by stirring thoroughly with acetone (about a litre for each extraction), pouring the pasty mass on to a folded Chardin filter paper, and finally pressing out through "jean." The clear acetone extract, which is of a dark-brown colour, is diluted with an equal volume of water. The precipitation of the picrate is completed by the addition of one volume of saturated aqueous picric acid, and the precipitate is allowed to settle overnight. This completes the first day's operations.

Second Day.—The clear, supernatant fluid is siphoned off and the picrate collected on a Buchner funnel. It occasionally happens that the picrate rises to the surface of the liquid, but this does not cause any inconvenience. It is washed with a dilute solution of picric acid and the moist picrate is converted into the hydrochloride by Dudley's method. For this purpose it is dissolved in acid alcohol prepared by mixing 25 c.cm. of 3N aqueous HCl with 75 c.cm. of alcohol. 10 to 20 c.cm. of this mixture are usually required for each gramme of picrate. By careful

* While this paper was being prepared for publication the authors learned in a private communication from Dr. Dudley that he had independently observed the solubility of insulin picrate in mixtures of water and alcohol, and that a paper by him, in which this observation is recorded, is now in the press.

rubbing with a glass rod, a turbid solution of a dark-brown colour is obtained, from which the hydrochloride is precipitated by the addition of 10 to 20 volumes of acetone. The hydrochloride is allowed to settle, and the clear supernatant fluid is decanted. The remainder is poured on to a Buchner funnel and the precipitate is washed with acetone until free from picric acid, and finally with dry ether. It is then dried in a vacuum desiccator overnight. The crude hydrochloride so obtained is a perfectly white, non-hygroscopic, amorphous powder, the rabbit unit of which usually lies between 3 to 6 mg. In some recent batches the rabbit unit has been as low as 1·5 to 2 mg.

Results.

The following are typical of the results obtained:—

1. *Exp. 8.*—Ox pancreas. Six kilos of dissected pancreas yielded 6·02 g. of hydrochloride. This was standardised in the usual method; 4, 6, and 8 mg. being given, and the rabbit unit was found to be 4 mg.

Rabbit No. 6, weight 2·2 kg. Blood taken at 7 P.M., 110 mg. per cent. Injection of 4 mg. in 1 c.cm. immediately after bleeding. Blood taken at 8 P.M., 59, at 9 P.M., 45, at 10 P.M., 48 mg. per cent. The total rabbit number of units was therefore 1504—i.e., 250 rabbit units per kg. The hydrochloride was then purified by Dudley's picrate process, and yielded 0·705 g. of pure hydrochloride. The rabbit unit of this was determined in the usual manner, 0·5, 1, and 1·5 mg. being given. It was found that 0·5 mg. was the required dose.

Rabbit No. 10, weight 2 kg. Blood taken 11 A.M., 125 mg. per cent. 0·5 mg. given in 1 c.cm. immediately after. Blood taken at 12.5 P.M., 33, at 12.55 P.M., 30, at 2 P.M., 42 mg. per cent. The total yield of purified hydrochloride, with a rabbit dose of 0·5 mg., was therefore 1400 rabbit units—i.e., 233 rabbit units per kg.

2. *Exp. 7.*—Pig pancreas. Two kilos of dissected pancreas. Owing to the fatty nature fully 20 minutes was allowed for each extraction. The yield of insulin was 1·346 g. On standardisation, the rabbit unit was 2 mg.; 1·5, 2, and 6 mg. were given to the rabbits.

Rabbit No. 5, weight 2 kg. Blood taken 2.30 P.M., 140 mg. per cent. 2 mg. immediately injected. Blood taken at 3.25 P.M., 66, at 4.30 P.M., 34, at 6 P.M., 40·8 mg. per cent. Convulsions at 4.30 P.M. The total yield was therefore 673 rabbit units—i.e., 337 units per kg. On purification by Dudley's method, yielded 0·232 g. of hydrochloride. The rabbit unit was found to be 0·3 mg.; 0·3, 0·6, and 1·0 mg. were given.

Rabbit No. 4, weight 2·3 kg. Blood taken at 10.15 A.M., 132 mg. per cent. Injection immediately of 0·3 mg. in 1 c.cm. Blood at 11.15 A.M., 34, at 12.15, 27, at 1.40, 55 mg. per cent. The total yield was therefore 773 rabbit units, or 386 per kg. This, it will be noted, is higher than the crude yield, the probable explanation being due to the inaccuracy of the rabbit methods of standardisation.

3. *Exp. 4.*—Horse pancreas. 4·5 kg. dissected pancreas extracted twice with 3 litres of 1 per cent. aqueous formic acid, yield of crude insulin 10·06 g. Rabbit unit 10 mg.; 10, 30, and 50 mg. were used.

Rabbit No. 3, weight 2·6 kg. Blood at 10.30, sugar 142 mg. per cent. Immediate injection of 10 mg. in 1 c.cm. Blood at 11.35, sugar 64, at 12.30, sugar 36, at 1.15, sugar 40 mg. per cent. The rabbit with 50 mg. had violent convulsions after two hours. The yield was therefore 1060 rabbit units—i.e., 235 units per kg. The crude hydrochloride was used for other purposes and was not purified.

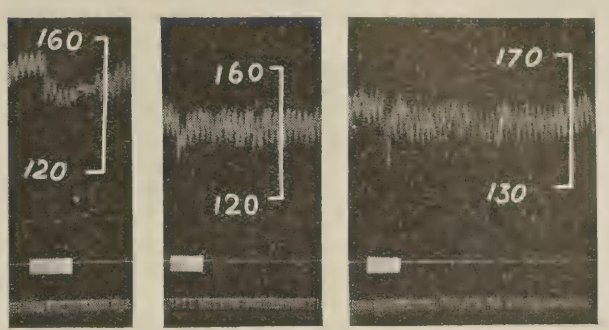
We have been able to repeat these experiments with consistent results, of which the above are typical instances. The yield has been steadily increasing with greater familiarity with the method.

As this process depends on quite different principles from the standard methods in use at the present time, it was thought necessary to test the possibility of a depressor effect. Prof. Swale Vincent and Dr. S. Wright very kindly performed blood-pressure experiments in the usual manner on two cats, the results of which we publish with their consent. The crude insulin hydrochloride made by this method was found to cause a very slight fall in blood pressure when injected intravenously. Twenty mg. containing 5 rabbit units caused a fall of 3 to 4 mm. (Tracing 1), but the purified hydrochloride was practically without depressor effect, as shown in Tracings No. 2 and 3. No. 2 represents the effect of 10 mg., No. 3 of 5 mg. of the purified hydrochloride, corresponding to 20 and 10 rabbit units respectively. The signal marks the time of injection.

These results are similar to those described by Dudley except in so far that the crude hydrochloride shows less depressor effect than crude insulin prepared by the alcohol process. Another important point is the question as to whether the final product contains any trypsin. To test this a previously standardised solution of hydrochloride was left in a 37° C. incubator overnight, and was re-standardised after incubation. The following are the details of the experiment.

The insulin made in Experiment 8 was used (see above). The rabbit unit, before incubation, was 0·5 mg. After incubation 1 c.cm., containing 0·5 mg., was injected into a rabbit with the following results: Blood at 11.5 A.M. 135 mg. per cent.; injection immediately after, blood at 12.5 P.M. 50, at 1 P.M. 40, at 2 P.M. 40 mg. per cent. From this experiment it is safe to conclude that the product is stable.

Blood-Pressure Tracings.



(1) crude ox 20 mg.; (2) pure ox 2 c.cm.; (3) pure ox 0·5 c.cm.

Insulin prepared by this method has been employed clinically on four human subjects and up to the present has been found quite satisfactory. No local reaction has been noted.

Conclusion.

This is intended merely as a preliminary communication. Many possible modifications suggest themselves. For example, improved yields might be obtained by distilling off in vacuo the acetone from the acetone picrate solution. Also the optimum concentration of acetone for the extraction of the picrates is now under investigation. From some experiments now in progress it appears that the insulin picrate might be fractionally precipitated from the acetone solution, thus yielding a purer product. Promising results have been obtained by alcohol and acetone alcohol extraction of the picrates. Modifications in the extracting fluid are also being investigated.

The object of publishing this preliminary note is to describe a workable water extraction process as an alternative to the lengthy and extensive alcohol extraction methods. The cost of materials in the present process is very small compared with that of the alcohol method, and the crude product can be prepared with ease in two days.

We wish to express our appreciation for the generous support of the Cancer and General Research Committee of the Middlesex Hospital. We have been in communication with Dr. Dale and Dr. Dudley of the scientific staff of the Medical Research Council and wish to express our thanks to them for their interest in this work, for information concerning details, at present in the press, of the method for the regeneration of the hydrochloride (included by their permission), and for many helpful suggestions with regard to the testing of the final product. The Medical Research Council also kindly provided facilities for the supply of pancreas used in these experiments.

THE USE OF THE X RAYS IN ANTE-NATAL WORK.

BY EDWARD W. H. SHENTON, M.R.C.S. ENG.,
LATE SENIOR RADIOGRAPHER, GUY'S HOSPITAL, LONDON;
AND
CHARLES H. S. HORWITZ, M.R.C.S. ENG.,
RESIDENT PHYSICIAN, LONDON HOME OF TWILIGHT SLEEP, STREATHAM, S.W.

IF asked to name the besetting difficulty of the obstetrician engaged to attend a woman having her first baby we should describe it as the satisfaction of his own conscience that there was sufficient room for the baby's head to pass through the maternal passages. Anything that can lighten his burden in this direction achieves great public service and deserves the greatest publicity.

According to text-books, mensuration of the female pelvis is a comparatively easy matter, but anyone whose task is to be constantly endeavouring to estimate the relative sizes of the baby's head to the bony pelvis, very soon arrives at a different conclusion. The administration of an anæsthetic is recommended in doubtful cases, so that with a relaxed abdominal wall one is more likely to be able to ascertain whether the head will enter the pelvic brim or not. But even here, we have found it most difficult in fat subjects, with a quantity of liquor amnii, to ascertain with anything like accuracy what was the true condition of affairs. It has been laid down by a well-known authority that often the only course to be adopted in borderline or doubtful cases is to allow a woman to go into labour and "wait and see." If serious difficulty is encountered, it is then one's duty to warn the mother that in future labours she will have either to submit to a Cæsarean section at full term or have an induction at the eighth month. Now, with the aid of X rays, a ready and easy means is provided for obtaining accurate knowledge of the size of the baby's head relative to that of the maternal pelvis. A glance at the illustrations, which have been traced from the radiogram obtained, will show that this is so.

FIG. 1.

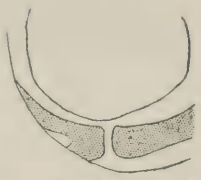

FIG. 2.

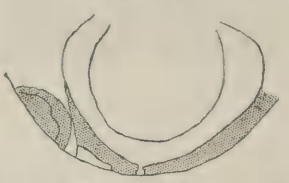

FIG. 3.

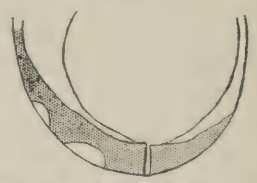

FIG. 4.

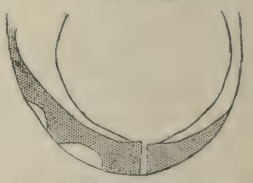

Diagrams traced from radiograms of the condition described in the text. Fig. 1 shows the head lying just above the pelvic brim. Figs. 2 and 3 show adequate disparity between the child's head and the pelvis. Fig. 4 shows that although the head is lying above the pelvic brim there is ample room for its passage into the cavity.

An Illustrative Case.

The subject from whom Fig. 1 was obtained was a very fat and apprehensive female. It was extremely difficult to know what the presentation was. There was nothing to be felt per vaginam, for nothing had entered the brim. From abdominal palpation we thought it was a breech, but were not certain, as there was an enormous amount of fat, fluid, and fussiness. We had her X rayed and nothing indicative of the head was seen below, so we were confirmed in our belief that the case was a pelvic presentation. We then did a version by external manipulation and applied a tight abdominal binder. The next X ray picture (Fig. 1) showed that our manipulations had been successful, for the head here is now lying just above the pelvic brim. Without the aid of the X rays we were up against this difficulty. There was just the possibility of the presentation being cephalic, and we were loath to do a version in those circumstances, for there might be a chance of bringing about the very thing it was our endeavour to avoid. Without the aid of the X ray we confess we should have allowed the woman to go into labour with the baby presenting by the breech—hoping that our suspicions were not correct. That would have entailed extra risk to both mother and child. A breech often means for the mother a bad perineal laceration, sometimes involving the rectum, and for the child premature inspiration and the swallowing of amniotic fluid with its concomitant risks. As it was, the result of the birth was in every way satisfactory except for details now to be mentioned peculiar to this particular case.

The patient had entered the home in order to have twilight sleep administered. She waited for five weeks, and, as nothing happened, and as she had entered the tenth month since the first day of her last period, a few bougies were introduced under anæsthesia, and labour started 12 hours later. As is usual with induction cases, labour is inclined to be slow and tedious, and for this reason twilight sleep is contra-indicated in such cases. The birth of the head and shoulders showed that the presentation was a left occiput anterior. There was no tear of the perineum, and the child was in every way normal and uninjured. It is a useful preliminary to the introduction of bougies to give injections of pituitrin, 0·5 c.cm. night and morning for three consecutive days prior to their introduction.

Cases Appropriate for This Method.

Our invariable custom now in a case about which we entertain any doubt—and to us there is always an element of doubt about any case of a primipara where the head is still above the brim of the pelvis during the last two weeks—is to have her X rayed. The knowledge so gained has proved of the greatest possible assistance. It is with a renewed sense of confidence and security that we then allow such a case to go into labour when the X ray has depicted an adequate disparity between the child's head and the pelvis, as, for instance, in Figs. 2 and 3. Only once in a fairly large number of cases now have we had reason to be at all disappointed with the X ray findings. Fig. 4 shows that although the head is lying above the pelvic brim there yet appears to be ample room for its passage into the cavity. We also believed so at the time, but subsequent events proved otherwise for there was a rather prominent sacral promontory. This entailed the application of forceps and a fairly hard tussle in order to get a well-ossified head past the obstruction. This difficulty has now been largely overcome by taking the photograph at a different angle, so that a view is obtained more directly down into the pelvis instead of a merely transverse view of the inlet, which can be so misleading when a well-marked promontory of the sacrum exists. A means now also exists of taking a radiogram of the outlet.

Another point about an X ray photograph is that some idea is obtained as to the amount of ossification the head has undergone, and that may be a real help in coming to some conclusion as to whether the child is overdue. It will be by the acquisition of this more accurate knowledge that X ray pictures undoubtedly afford, that the adoption of procedures suitable for particular cases will be more practised, and will render less exacting the life of the obstetrician.

Since writing on the subject of X rays in obstetric practice in 1922 [1] one of us (E. W. H. S.) has had the

[1] THE LANCET, 1922 i., 860.

opportunity of examining many pregnant women with X rays. The technical difficulties have disappeared with practice, and it is now a quick and simple process to give the obstetrician the few simple facts which conduce to safe delivery. Formerly much time has been spent in devising a system of pelvimetry, but however accurately the pelvis was measured, we were still left in doubt as to the size of the head. What really matters is not the absolute but the relative measurements of head and pelvis; and these measurements are readily obtained by radiography, for it needs no special training to say whether the head will or will not pass through the pelvic canal.

We do not think we are overstating the case when we say that this is the only method yet discovered which can clear up all doubts on the subject. One of us (C. H. S. H.), who has had more than usual opportunities of judging, can testify to the value of this method regarding the position of the fœtus. As we have pointed out before, there is not the slightest risk to mother or child, the X ray exposure merely being that of any ordinary body examination, the fœtus being exceptionally well protected by the fluid. Furthermore, newly-born babies show complete immunity to ordinary X ray exposure. In 25 years' experience, one of use (E. W. H. S.) has never seen any X ray reaction, although one has continually to examine babies for swallowed foreign bodies, pyloric obstruction, or other causes. Another attraction, perhaps not a very important one, is that the examination is devoid of any of the disagreeableness associated with manual manipulation.

Regarding the time at which ossification makes the fœtus visible, we are of opinion that this will vary considerably. A recent case, systematically watched from the third month, only became visible at the beginning of the seventh month. Stereoscopy has proved of value in a few cases, and it is a matter of extraordinary interest to see the fœtal head and the surrounding bones in relief.

Clinical and Laboratory Notes.

NOTES ON TWO CASES OF HÆMOPERITONEUM DUE TO RUPTURE OF BLOOD-VESSELS IN THE GASTRO-SPLENIC OMENTUM.

By RODNEY MAINGOT, F.R.C.S. ENG.,

CHIEF ASSISTANT TO A SURGICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL; HON. SURGICAL REGISTRAR, WEST LONDON HOSPITAL.

HÆMOPERITONEUM due to rupture of the blood-vessels in the gastro-splenic omentum following on an external injury is a rare occurrence; and these cases are recorded as they possess many points of similarity and general interest.

CASE 1.—Female, aged 5, admitted to the West London Hospital on Dec. 3rd, 1923, in a collapsed condition. This little girl was run over in the street by a milk-cart, the wheel of which passed over her abdomen.

Condition on Admission.—She was brought to hospital half an hour after the accident. Her pulse was then 160 and almost imperceptible at the wrist. Temperature 96° F., respirations—very shallow and rapid—about 44 to the minute. The child was dyspnœic, cyanosed, and restless. Pupils widely dilated. Many superficial abrasions were present. Small cut over right iliac fossa. Examination revealed no fracture of ribs, spine, or limbs. Thorax normal. The abdomen was "board-like" in its rigidity, and tender all over, but particularly on the left side: Shifting dullness detected in left flank. No decrease of liver dullness. Urine clear. As the patient appeared to be rapidly sinking, immediate cœliotomy was decided upon.

Operation.—This was performed about one hour after the accident, under ether, gas, and oxygen anæsthesia. Right paramedian incision 4 inches long. Peritoneum full of fresh blood, contained some large semi-solid clots in pelvis. The various portions of the gastro-intestinal tract were systematically examined and found to be normal. Urinary bladder, liver, and renal areas appeared intact. A small tear, however, was located in the gastro-splenic omentum, and a small spurting blood-vessel was identified, seized with pressure forceps, and ligatured. The abdominal cavity was then washed out free of all blood and clots, and about half a pint of hot normal saline was allowed to remain inside. The wound was closed up in the usual manner. During the operation 1 pint of normal saline was administered subcutaneously; and 1/120 gr. of strychnine hydrochloride was injected into the left ventricle during a temporary cessation of the heart's beat.

Although the patient was practicaly moribund after the operation, she rallied gallantly, and after withstanding a severe attack of acute bronchitis, made a good recovery.

CASE 2.—Male, aged 15, was "run over" by a taxi-cab whilst wheeling a barrow. He stated that one wheel passed over his abdomen. He was brought to the West London Hospital on Nov. 12th, 1923, about an hour after the accident, when he complained of severe abdominal pain, thirst, and difficulty in breathing.

Condition on Admission.—Temperature 97° F., pulse 112, respirations 22. The patient was very pale, restless, slightly cyanosed, dyspnœic, and sweating freely. Nothing abnormal detected in thorax. No clinical evidence of any fracture. Epigastrium very rigid and tender. Shifting dullness detected. Catheter passed. Urine normal. Five hours later, T. 97°, P. 130, R. 30. Vomited once. No blood in vomit. Rigidity of abdominal muscles more marked. Per rectum, tender.

Operation.—Ten hours after accident, under gas and oxygen anæsthesia. Right paramedian incision 3½ inches in length. Abdomen contained fresh blood and some blood clots. All abdominal viscera examined found to be intact. A diffuse bleeding area was discovered in gastro-splenic omentum. This area was firmly packed with gauze, one end of which was brought out into the left flank through a separate "stab" wound. The abdomen was then closed after removal of the large blood clots. The gauze packing was removed after 48 hours.

This patient made a gratifying recovery, and left hospital a fortnight after his operation. This case (No. 2) was admitted under the care of Mr. Donald Armour, and I am indebted to him for his kind permission in allowing me to publish his notes.

A CASE OF SMALL SUB-PERIOSTEAL FIBROMA OF THE TIBIA.

By JOHN A. C. MACEWEN, M.B., C.M., F.R.F.P.S. GLASG.,

SURGEON ROYAL INFIRMARY AND DISTRICT HOSPITALS, GLASGOW.

THIS case of small sub-periosteal fibroma of the tibia caused much pain in the leg and localised tenderness.

A woman, aged 24, was admitted to Oakbank Hospital complaining of dull aching pain and slight swelling of the right lower limb of one year's duration. The pain, which was most marked over lower third of tibia, was also experienced in the hip- and knee-joints on movement, and was increased by the pressure of the bedclothes. Examination was negative save that the leg, which appeared to be slightly swollen, but did not pit on pressure, was exquisitely tender about the junction of the middle and lower third of the tibia. X ray photographs showed no abnormality of the bone, the joints appeared quite normal, and the Wassermann reaction was negative. Rest in bed did not alleviate the symptoms.

Operation.—An exploratory incision was made over the tender spot, and a small hard tumour, the size of a lentil, was removed from a depression on the surface of the tibia, underneath the periosteum.

The pathological report stated that the tumour presented the structure of a fibroma, with interlacing bundles.

The patient made a perfect recovery, the pain and swelling disappearing entirely, so that she is now fit for her regular work.

I am indebted to Dr. Janet A. O. Weir, resident at Oakbank Hospital, for the preparation of the report on this case.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

A MEETING of this Society was held at 11, Chandos-street, Cavendish-square, W., on Feb. 11th, Dr. HERBERT SPENCER being in the chair, when a discussion was held on the

General Symptoms and Remote Manifestations of Common Affections of the Nasopharynx, the Nasal Accessory Sinuses, and the Throat.

Mr. HERBERT TILLEY, in opening the discussion, said that he would limit his remarks to conditions of inflammatory origin, and largely restricted himself to a demonstration by lantern-slides of the chief points of interest in his communication. Diseases of the nasopharynx, he said, were largely the pathological conditions which affected the lymphoid tissue of the post-nasal space. The well-defined but anatomically connected deposits of lymphoid or adenoid tissue grouped around the nasopharyngeal and faucial regions, forming what was known as Waldeyer's ring comprised the lymphoid tissue of the nasopharynx, the palatine or faucial tonsils, and the lingual tonsils. Lymphatic vessels passed from each of these to well-defined groups of cervical glands in the anterior or posterior triangles of the neck. There were also, in children, up to the third or fourth year, two pairs of lymphatic glands between the posterior wall of the pharynx and the anterior surface of the second and third cervical vertebræ. The common form of retropharyngeal abscess was the result of inflammation and suppuration in these glands. Histologically these lymphoid structures were essentially identical, and pathological conditions were rarely limited to any one of them. It was well-known that these aggregations were normal and well-defined structures in the earlier years of childhood, and that they exhibited a marked tendency to involution about the age of puberty and during the period of adolescence, but it was often forgotten that such a change might not take place, and consequently pathological conditions of these lymphoid collections were not uncommon in adult life. Their function scarcely came within the title of the discussion, but had an important bearing upon it.

Amongst other contributions the work of Kenelm Digby, Good (Chicago), and Dudley (Medical Research Council) went far to prove that the phagocytes of the tonsils, Peyer's patches and other sub-epithelial solitary lymph glands were continually ingesting the adjacent bacteria in the nasal and alimentary channels, and thereby constantly producing a healthily acquired immunity against various infections. It would be an extremely valuable piece of information if the medical officers of fever hospitals could show what sort of response to infection has been made by patients whose tonsils and adenoids had been completely removed in comparison with those who still possessed a normal amount of those tissues.

The lymphoid tonsillar deposits were well-developed in children. Their reaction to infection, as well as that of their associated cervical glands, suggested that they acted as protective structures in the first and second "lines of defence" respectively. At varying periods of time after complete removal of the faucial tonsils their recesses were occasionally seen to be partially occupied by lymphoid tissue which had grown up from the adjacent lingual tonsils. These were not a recurrence, but simply a pushing up of tissue into that place. In other instances prominent longitudinal deposits of a similar nature occupied the lateral walls of the pharynx. Quite recently he had seen a boy, aged 10, who four years before had his adenoids removed and tonsils enucleated. On the posterior pharyngeal wall there were the largest "granulations" of lymphoid tissue he had ever seen, which were probably the cause of the chronic "dry cough" from which relief was sought. Nature, apparently, had some very definite reason for placing sub-epithelial lymphatic tissue in those situations; thus such structures should not be sacrificed without more consideration than is often given to the question of their removal. Whether the constituents of Waldeyer's ring furnished an internal secretion akin to those of the endocrine glands was a view at present based rather upon theoretical considerations than on clinical observation and experience.

Effects of Inflammation.

With regard to the evil results which may follow when pathological conditions affect any one or more of the constituents of the lymphatic ring, the chief interest centred around the effects produced by inflammation arising from infection by pathogenic or pyogenic organisms, or both. The most frequent result, and especially after recurrent attacks of inflammation, was that hypertrophy of the lymphoid tissue known as "adenoids and tonsils"—i.e., the existence of an abnormal amount of lymphoid tissue in the nasopharynx and in the recesses between the faucial pillars. While hyperplasia was the usual result of inflammation during childhood it was important to bear in mind that pathological conditions might exist *without* hypertrophic changes, in which case the remoter manifestations were often more prominent than the local evidences of disease. Such considerations rendered it easier to answer the question, "What do we mean by *diseased* tonsils and adenoids?" The pathologist might hold that the mere presence of purulent debris and micro-organisms in their crypts and recesses was only an expression of physiological activity, while epithelial abrasions and the existence of polymorphonuclear leucocytes should be regarded as a surer sign of disease. The practical clinician would probably, and, he thought, rightly, maintain that the question could be answered only by an investigation of the history of the symptoms and of all the factors presented by the individual case.

Adenoids.

It was a common experience to meet this affection without a corresponding hypertrophy of the faucial tonsils, but less frequent to find the latter condition without some overgrowth of the nasopharyngeal lymphoid tissue. The general symptoms caused by adenoids might be divided into three categories according to the most prominent type of symptoms produced—viz.: (1) Those which indicate obstruction of the upper air passages; (2) local or remote symptoms of infection; (1) disturbance of reflex origin.

The Throat.

The commoner affections of the throat were due to inflammation of the palatine or faucial tonsils. The general symptoms of the commoner types of acute inflammation or tonsillitis were well known; their clinical manifestations were determined by the nature and virulence of the infecting organisms, their site of entry, and the resisting power of the patient. Other things being equal, the local and constitutional symptoms would be more severe should the predominating organism be a virulent type of streptococcus than in the case of staphylococcal or pneumococcal infection. The site of invasion had led to the recognition of at least three types of acute tonsillitis: (1) lacunar tonsillitis, where the brunt of the inflammation affects the crypts or lacunæ (often spoken of as "ulcerated sore throat"); (2) parenchymatous tonsillitis, in which the lymphoid follicles were acutely inflamed; (3) peritonsillitis or quinsy, where, while the tonsil was always inflamed, the characteristic lesion was inflammation and suppuration in the cellular tissues outside the capsule of the tonsil terminating in an abscess. This usually "pointed" in the soft palate above and to the outer side of the tonsil.

It was usual to recognise at least three types of chronic inflammation—viz., (1) chronic lacunar tonsillitis, where the crypts were filled with inflam-

matory products and swarming with micro-organisms; (2) hyperplasia of the lymphoid follicles, which produced large, soft tonsils of varying size and shape; (3) fibroid degeneration, in which connective tissue preponderated at the expense of the lymphoid elements.

Tuberculosis of the Tonsils.

As was the case in adenoids, tuberculosis of the tonsils was not infrequent, being latent and exhibiting no clinical signs of its presence. Philip Mitchell stated that of 64 children with tuberculous glands in the neck, 24 showed histological evidence of tuberculosis of the tonsils. The remoter manifestations of chronic tonsillitis were second only in importance to infective conditions of the teeth. In addition to ill-defined symptoms of impaired general health many definite and localised lesions had been proved to be due to a focus of infection in the tonsils. Such was the case with respect to fibrositis, myositis, and chronic arthritis.

The Nasal Accessory Sinuses.

These comprised the maxillary, ethmoid, frontal, and sphenoidal sinuses. The most common affections of these air-cells resulted from invasion by infective organisms, and the consequent inflammation assumed an acute, subacute, or chronic form. If the nasal accessory sinuses were methodically investigated during the post-mortem examinations of all cases of acute meningitis it would be found that a large number were the result of unsuspected infection from the sphenoidal and ethmoidal air-cells. Concerning the remoter manifestations of accessory sinus disease in adults it was his experience that gastric, pulmonary, and ocular symptoms are more frequent than cardiac, muscular, or arthritic complications. The constant swallowing or inhalation of septic matter is probably responsible for the first two. The pulmonary affections referred to are chronic bronchial catarrh, bronchitis, and not infrequently asthma. In consulting his physician for these complaints the patient often made no mention of a previous "chronic nasal catarrh," which only caused an inconvenience, because to him the pulmonary trouble is the real grievance. The great majority of chronic nasal catarrhs were really muco-purulent discharges from the nasal sinuses, and the infective micro-organisms which caused them would often be found in the patient's expectoration. Still more important was the fact that if the source of infection be removed its complications in the lower air-passages would often disappear without any special treatment.

Discussion.

The PRESIDENT expressed his appreciation of the caution advised by Mr. Tilley; in view of the tortuous cavities which had been so well illustrated upon the screen, operation in these cases was very difficult, and treatment of the conditions referred to should be left to specialists.

Sir HUMPHRY ROLLESTON said that the problems raised were on much the same lines as those in connexion with oral sepsis and formed part of the wider conception of focal infections. The common affections of the throat and naso-pharynx were especially prone to lead, by a process of direct spread, to disorders of the respiratory tract—laryngitis and bronchitis; a special form of this sequence of events was seen in post-operative lung complications, which in the past were often explained as pulmonary embolism; but according to Whipple, who called the condition pneumonitis, were commonly due to pneumococcus type IV. As with the teeth, so with the infections in the naso-pharynx and adjacent parts, a distinction between discharge into the alimentary canal on the one hand and into the lymphatic or blood-stream on the other hand, seemed important; the distinction must not, however, be pressed too far, for hæmatogenous infection, especially of the gall-bladder, might occur in the abdominal viscera. Much inflammatory disturbance of the tonsils, sinuses, &c., might exist, for a time at any rate, without any obvious general or remote manifestations. As in the more acute fevers, there was an incubation period, sometimes lasting for years, during which the process of sensitisation of parts of the body apparently took place. But as a cause of the sudden outburst of general or remote manifestations in a previously latent case of such a kind, the occurrence of a secondary infection must be admitted; and further, the chronic absorption of toxic products might have sapped the patient's powers of resistance and prepared the way for the new infection. The conception of local sensitisation of tissues, for example, of the articular structures, to toxins absorbed from the tonsils and sinuses was also of interest in connexion with Rosenow's view that bacteria have very special affinities for certain tissues, for example, streptococci from the tonsils are prone to select the joints, muscles, and the gall-bladder. A female patient, who was having a streptococcic vaccine, had attacks of biliary colic which seemed to be definitely related to the vaccines; the latter were stopped on the hypothesis that they set up cholecystitis in a sensitised gall-bladder. This stoppage was followed by cessation of the biliary attacks, and for six months all seemed well, but then the biliary attacks recurred and operation revealed numerous small calculi in the gall-bladder. The vaccine might have set up cholecystic reaction and extrusion of the calculi, but these alone might as a series of coincidences have caused the colic. A difficult point concerned with secondary or mixed infections of the throat was to distinguish between those which give rise to rheumatism—namely, manifestations held in check, if not abolished, by efficient salicylate treatment—and those which, not being thus restrained, were more virulent. Probably these conditions might occur together, and then at the best only a temporary improvement followed salicylate.

Dr. JOHN POYNTON dwelt on the connexion between tonsillitis and acute rheumatism. In 1900 he and Dr. Paine had isolated a diplococcus from the mitral and aortic valves of a case of heart disease, and had by means of this organism produced experimental rheumatic lesions. He looked upon the tonsils as a first line of defence, which might, if damaged, become a source of danger, in which case they must be removed. Removal, however, could not be relied upon to prevent further attacks of any particular condition. There was difficulty in defining a healthy tonsil, although much was known concerning infection. With regard to appendicitis, he had used a micrococcus from a boy with rheumatoid arthritis to produce experimental appendicitis, from which he had recovered the organism used. He showed slides illustrative of experimental appendicitis, pointing out how the infective organisms were taken up by the lymph cells, which were there shown to be exercising a defensive function. He also referred to the frequency of acute tonsillitis in leukæmia. He believed that some day the so-called blood diseases would be recognised as examples of abnormal reactions to forms of blood infection.

Sir STCLAIR THOMSON spoke of the extent of the subject, remarking that one evening could easily be spent in discussing the remote manifestations of infections of tonsils and another to those of infections of adenoids. Nasal obstruction, catarrh, and interference with breathing and swallowing were the chief symptoms handled by the specialist, and were therefore not included in the discussion. The specialist could, however, suggest two points to assist the family physician to recognise disease of the accessory sinuses: (1) a bad smell from the nose, observed by the patient; (2) the presence of pus, whether appearing in the nasal discharge or in the post-nasal space. He uttered a warning against too active surgery in the cases under discussion; it was advisable to operate "à froid," not "à chaud." He showed several slides of charts illustrating the prolonged fever sometimes caused by the presence of pus in the nose.

Mr. W. M. MOLLISON said that there was scarcely a disease for which the surgeon was not sometimes asked to remove the tonsils; he proposed to deal

only with nephritis as a result of tonsillitis. The surgeon was usually called in after the first attack of nephritis; albuminuria and hæmaturia generally increased immediately after operation for removal of tonsils, but later they disappeared. A. A. Osman had found that at Guy's Hospital, of a series of over 60 cases of nephritis, 55 per cent. had begun with tonsillitis. He (Mr. Mollison) recalled a case of a girl, aged 26, who had had two attacks of acute nephritis following acute tonsillitis. He had removed the tonsils, and heard two or three years after from the physician in charge of the case that the patient had had no further attack of acute nephritis, and showed a very slight degree of albuminuria. In other cases he had found albuminuria persist after removal of tonsils.

Dr. E. M. CALLENDER spoke of the pitfalls of the subject from the general practitioner's point of view. He agreed that Waldeyer's ring constituted a first line of defence against infection. He could remember no child in his own practice who had had the naso-pharynx cleared and had thereafter shown more liability to disease; if anything, he sometimes thought, these children were less liable to be infected than others. The general practitioner saw the beginnings of disease, but those beginnings were sometimes very difficult to recognise; he instanced a case where he had been called to a girl who was stated to be suffering from "a touch of sun," who presented only an ordinary febrile condition, only complained of a sore throat 24 hours later, and developed a tonsillitis 24 hours later still. During the war, in both England and France, he had been struck by the numbers of men with chronic otorrhœa; the latter seemed to go on all right with free drainage, but there was no free drainage in infections of the accessory sinuses. The most frequent form of such infections was the common cold—preventable, he thought, if taken before the bacilli were buried in the inflamed mucous membrane. He divided colds into those caused by *B. catarrhalis* and those caused by the pneumococcus.

Mr. E. D. D. DAVIS named many conditions for which he had been asked to remove tonsils. The tonsils, being specialised lymphatic glands, must always be examined before other less likely causes of illness were considered. Experience had not convinced him that colds were any less frequent after tonsillar operations.

Dr. WILLIAM HILL recalled that in his student days, before the discovery of the Klebs-Löffler bacillus, he was taught that albuminuria should be searched for in acute tonsillitis, and that if albuminuria was present the case was probably diphtheria rather than acute tonsillitis. He had found in his own experience that this idea would not fit in with facts.

Mr. TILLEY briefly replied.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Feb. 7th, Dr. ELIOT CURWEN, the President, being in the chair.

Prof. HUGH MACLEAN read a paper on the

Present Position of Renal Disease and Albuminuria.

He considered many of the older methods for testing the efficiency of the kidneys were of very little value, and at the present date unnecessary. The urea-concentration test—which is of a simple character, not expensive, and capable of being carried out by any general practitioner in a few minutes—was the most efficient and satisfactory. Albumin in the urine he did not consider so serious a symptom as was formerly thought. A small portion of the kidney might be disorganised, permitting the transudation of albumin, whilst the remainder was in a healthy condition and capable of carrying on the full functions. Rest and warmth are the chief lines of treatment. Washing out the kidney with large draughts of water he did not consider of much use as the kidney in the diseased state was incapable of excreting the water. Great reduction of protein food was not only considered unnecessary but in some cases harmful.—A vote of thanks was proposed by Dr. E. F. MAYNARD, seconded by Dr. R. SANDERSON, and carried unanimously.

Dr. H. M. GALT showed microscopical slides of (1) injected kidney, (2) normal human kidney (stained), (3) kidney in advanced interstitial nephritis, (4) kidney showing early amyloid change.

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

A MEETING of this Society was held on Feb. 1st, with Dr. A. MAITLAND RAMSAY, the President, in the chair.

Dr. A. E. MILNER gave a communication on the

Treatment of Lupus Vulgaris by the Diathermy Current.

After a brief description of the current and the form of apparatus used, Dr. Milner explained in detail the method he employed in the treatment of lupus vulgaris. The patient is placed on the condenser couch and the diathermy current turned on. The operator approximates a well-earthed electrode about the thickness of a darning needle to a distance of one-sixteenth of an inch from the part to be treated, when a succession of sparks passes from the patient to the electrode. A general anæsthetic is essential, and, of course, the danger of ether in the presence of sparks must be remembered. The area to be treated is first circumscribed by a ring of sparks, leaving about one-eighth inch of healthy tissue around it, and is then systematically cauterised over the entire surface. A dressing of calamine and bismuth cream is employed thereafter. A few cases are cured by one treatment, but usually two or three are necessary. The resulting scar is surprisingly good and scarcely noticeable. Should the scar be at all thick owing to previous treatment of the lupus with other methods, the application of X rays is effective. Dr. Milner had found that the most favourable case to treat was lupus vulgaris simplex, and emphasised the necessity of ensuring that every diseased part was accessible to the spark. He had found the results unsatisfactory in the cases where there was, in addition to the lupus, tuberculous disease of the mucous membrane of the nose, mouth, or lacrymal apparatus, as reinfection of the wound almost invariably took place.

The analysis of cases treated, excluding all cases in which the nasal or other mucous membranes were affected with lupus, was as follows: Total number of cases treated, 60; cases cured, 42; total number of operations performed on cases cured, 145; cured by one operation, 5; cured by two operations, 5; average number of operations on cases cured, 3·5; average time occupied in treatment of each case, 3·4 months. Time since cure was effected: Over 4 years, 1 case; over 3 years, 13 cases; over 2 years, 6 cases; under 2 years, 22 cases.

Dr. A. BRUCE MACLEAN described the results of the treatment of a variety of cases by

Medical Diathermy.

He had found the best results in the following types of case: (1) Fibrositis; where definite nodules can be felt. These nodes were usually rendered painless after a few applications, and often disappeared in a few weeks. (2) Neuritic pains and neuralgias; sciatica responded well to four to six treatments of about 40 minutes each. (3) Arthritis. Although little influence could be exerted on the disease, relief of pain could nearly always be obtained. (4) Circulatory disturbances; particularly those in which a

gh blood pressure was the important factor, as the athermy current had a marked influence in the duction of the blood pressure. (5) Gynæcological ases—e.g., ovarian neuralgia, dysmenorrhœa, &c.

Dr. LAWRENCE STEWART, in the absence of Dr. AMES R. RIDDELL, showed a series of cases of odent ulcer treated by the diathermy spark.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTIONS OF MEDICINE AND SURGERY.

A JOINT meeting of these sections was held in the Royal College of Physicians of Ireland on Jan. 25th. The President of the Surgical Section, Sir WILLIAM . DE COURCY WHEELER, was in the chair.

JAUNDICE.

In opening the discussion on this subject Mr.). P. D. WILKIE (Edinburgh) said that he felt joint iscussions were most useful, and he was of opinion hat close coöperation between physicians and surgeons vas essential. One form of hæmolytic jaundice was ongenital, and it was the exception rather than the ule for surgeons to be called on in such cases. Removal of the spleen in cases of hæmolytic jaundice vas being widely practised in recent years. He ersonally had performed this operation with great uccess in cases of the acquired type of hæmolytic aundice, but these cases were relatively rare. He was of opinion that the diagnosis of jaundice cases was of he greatest importance, because the different forms of treatment were decided on according to the diagnosis. If a surgeon saw a case of jaundice which had been liagnosed as obstructive jaundice, he usually thought hat it might be due to gall-stones, and at operation ie looked out for these. Causes of obstruction of the ile-ducts other than stone or malignant disease were liscussed, including pancreatitis and cicatricial con- raction following such operations as cholecystectomy. When the gall-bladder was available and the obstruc- tion to the biliary passages could not be removed, cholecystenterostomy, and particularly cholecysto- gastrostomy, gave excellent results. The operation of anastomosing the common hepatic duct to the duodenum was attended with considerable risk, particularly if the patient was very jaundiced, and the greatest risk was that of hæmorrhage. This could be diminished by decreasing the coagulation-time of the blood by means of intramuscular injections of 15 c.cm. of a 30 per cent. solution of sodium citrate into each buttock, following the method of Neuhof and Hirschfeld. These injections were painful unless preceded by a local anæsthetic such as novocaine. The method of lessening coagulation-time introduced by Lee and Vincent and advocated by Walters at the Mayo Clinic, by injecting 5 c.cm. of a 10 per cent. solution of calcium chloride three times daily for three days before operation, had not given satisfactory results in Edinburgh, and had been discarded in favour of the intramuscular injection of sodium citrate. Recently, blood transfusion had been done before operation, and if there was much bleeding after operation it was repeated. There was also the danger of hepatic insufficiency, as a result of which patients frequently did very well for the first few days after operation, but became ill about the third day and died soon afterwards in a state of coma. This could be guarded against to some extent by giving glucose by the mouth or subcutaneously, before operation: experiment had shown that life could be greatly prolonged in a dog deprived of its liver by giving glucose. Hot packs to the liver were useful in combating post-operative hepatic shock. Mr. Wilkie dealt in this connexion with the "white bile" which was found occasionally filling the bile-ducts and the gall-bladder in cases of obstructive jaundice. He described the fluid as crystal clear and approximating more closely the composition of distilled water than any other fluid found in any circumstance in the human body. When the obstruction was relieved in these cases and the patient lived, biliary secretion of normal colour and constitution reappeared within a few days. Coloured drawings were shown illustrating the effects of experimental ligations of the biliary ducts, demonstrating that "white bile" was a secretion of the ducts themselves, which sometimes, in the human subject, continued when the activity of the liver cells was in abeyance. Renal insufficiency also had to be considered.

The van den Bergh Test.

Dr. T. G. MOORHEAD said that from a physician's point of view jaundice was not a very satisfactory subject to deal with. A great deal had been learned in recent years concerning the pathology and ætiology of jaundice, but no real advance had taken place in its treatment. There was no gland in the body over which the physicians seemed to have less power, as far as remedies were concerned, than over the liver. He agreed fully with Mr. Wilkie that the most important thing for the physician to do was to arrive at an accurate diagnosis, and in this respect an advance had been made by the introduction of the van den Bergh test, but unfortunately, this test had proved less satisfactory than was at first hoped. Since the appearance of McNee's paper in the *British Medical Journal* of May, 1922, he personally, and many others, had been working with the test. It was at first hoped that it would enable the physician to distinguish between obstructive jaundice and toxic jaundice, but this hope had proved fallacious. Dr. Moorhead hoped, therefore, that further experience in or modification of the test would soon be produced. Where diagnosis was impossible he felt that an exploratory laparatomy should be performed, if conditions were not improving with the patient, after a lapse of some weeks. Even as a physician he would rather have an unnecessary laparotomy performed than fail to recommend one which might do good. He would like to add his testimony to that of Mr. Wilkie regarding the success of cholecysto-gastrostomy in suitable cases, and lastly, he would like to say that in many gall-stone cases, in which jaundice did not develop, operation was not essential.

Dr. ALFRED R. PARSONS referred to the van den Bergh test, and said that, as far as his own experience went, the test certainly demonstrated by the different reaction obtained that the type of bilirubin found in the blood in hæmolytic jaundice differed from that found in obstructive jaundice.

Practical Points in Prognosis.

The CHAIRMAN drew attention to certain practical points affecting the prognosis in cases of obstructive jaundice. He said that (1) surgeons in the past rather dreaded the possibility of post-operative oozing of blood into the general peritoneal cavity and recently papers were published indicating that probably a 58 per cent. mortality could be traced in part to slow intra-abdominal hæmorrhage. He referred to the recent work of Walters, Vincent, Lee, and others in administering calcium chloride to quicken the coagulation-time of the blood. Calcium also combined with the bile pigments in the blood-stream and so reduced toxæmia. (2) Much attention had been recently focused on the presence of white bile found in the ducts in cases of obstruction, and on the high mortality which followed any operative treatment in such cases. The term "white bile" was a misnomer; it was a colourless fluid secreted by the glands lining the ducts, and indicated hepatic insufficiency following obstruction. The patient might or might not be jaundiced, and thick, black bile was found in a non-functioning gall-bladder, the result of stasis. The bile had probably remained in the gall-bladder for a considerable time, and must not be mistaken for fresh bile passed into the gall-bladder from a functionating liver. (3) The prognosis was bad, he held, if bile did not appear soon after the establishment of drainage in cases of jaundice.

or if only a little came for a few days and then stopped. In these cases the prolonged back-pressure on the liver had probably caused such injury to the hepatic cells that there was cessation of function which, if not quickly restored, was followed by death. (4) A sudden flow of bile flooding the operative field in cases of obstruction gave anxiety. Such sudden relief of back-pressure had a similar effect on the liver as sudden relief of back-pressure had on the kidneys. The liver became engorged with blood as the result of sudden emptying of the bile-ducts, and the condition known as "liver shock" might follow a few hours after operation. In these cases surgeons endeavoured to decompress the liver gradually by keeping a clamp on the tube and allowing small quantities of bile to escape at regulated intervals.

The Chairman further referred to the reports he had made to the Academy of Medicine on the results of the Talma-Morison operation in 1904. In 1914 he reported a case referred to him by Dr. Parsons, in which tapping of the abdomen was resorted to with ever-shortening intervals until the patient became emaciated and confined to bed. At operation the liver was found fibrous, hard, and contracted to less than half the normal size. The operation did not cure the patient's weakness for indulgence in alcohol, but otherwise he remained well to this day. At the time when these early cases were reported, jaundice was considered a contra-indication to operation in cases of hepatic cirrhosis. Kocher, in his text-book, referred to the work done in Dublin in connexion with this subject, but thought that the operation, with certain precautions, would be successful even in the presence of jaundice.

The Rôle of the Spleen in Jaundice.

Considering recent work on the rôle of the spleen in cases of cirrhosis of the liver and jaundice, all were agreed on the excellent results which followed splenectomy in hæmolytic jaundice and Banti's disease; but it had not been so generally accepted that certain cases of cirrhosis of the liver responded satisfactorily to the same operation. According to Mayo, approximately one-fourth of the total blood in the portal circulation came from the spleen. A spleen over-burdened with toxic blood might deliver an unfinished product and be directly responsible for hepatic cirrhosis; and again, if cirrhosis arose independently, the hepatic cells which had a high power of regeneration might be relieved by stopping the blood flow from the spleen; the underlying principle being the same as in the Talma-Morison operation.

DR LEONARD ABRAHAMSON said that for some time it was believed that infectious jaundice was due to associated infection of the bile-ducts, but latterly it had been found that these cases were really due to septicæmia. It was probable that the mode of infection was the blood-stream, and that if blood cultures were done sufficiently often, organisms would be found in the blood-stream. If cases of catarrhal jaundice were seen early enough, and blood cultures were done in every case, he thought it would be an advance in the treatment of jaundice. In French schools they thought that there were three types of jaundice: (1) the definitely obstructive type; (2) the definitely hæmolytic type; and (3) the toxæmic type. Cases of jaundice were often seen in which there was retention of the bile-pigments, but no retention of bile-salts, or in which there was retention of the bile-salts, and not of the bile-pigments. Up to the present, there was really no good test for liver insufficiency. He would like to know if in cases which were operated on for jaundice horse serum had any value in preventing hæmorrhage. He had seen horse serum given in one case only, but in that case there had been practically no hæmorrhage. Urobilinogen was found frequently in the urine of jaundiced patients, and he believed this showed liver deficiency. Cases of heart failure in which there was definite jaundice were generally fatal, and he would like to know what the actual cause of death in such cases was.

Mr. C. J. MACAULEY said that, in his opinion, surgeons were too inclined to take over a case straight from a physician and operate at once without being confident enough of the diagnosis, and commented on the points which had been raised about renal insufficiency and hepatic insufficiency.

Dr. HENRY MOORE said that in nearly every case of jaundice in his experience bile was found in the stomach contents at some time during the three-hour period, and yet in some cases he had come across the bile did not seem to cause the patients very much inconvenience. He quite agreed with Dr. Abrahamson that there was no very reliable test for liver insufficiency. He believed a new test had recently been invented by the Americans. He did not think much information could be got by testing substances, he would rely more upon functional tests.

Sir WILLIAM TAYLOR said he thought that in a great many cases the bad effects after operation could be avoided if more care was taken in diagnosis. He did not agree with Dr. Moorhead that a patient with gall-stones should not be operated on. He would operate on every case of gall-stones, provided the patient had sufficient symptoms to justify a definite diagnosis of gall-stones.

UNIVERSITY COLLEGE, CORK, SCIENTIFIC AND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of the Medical Section of this Society was held on Jan. 29th, with Dr. D. MORRISSY in the chair.

Dr. J. B. HORGAN presented a case of mastoid suppuration in a male aged 30 years, which illustrated the difficulties of diagnosis of a suspected lateral sinus thrombosis. Symptoms and temperature showed no abatement some three days after a radical operation for the relief of an acute exacerbation of a chronic suppurative otitis media. Examination of cerebro-spinal fluid showed a normal fluid, the lungs were normal, and examination of the blood gave no indication beyond a relative preponderance of polymorphs in an otherwise normal white-cell count. There were no rigors or chilly feelings. The temperature still running an intermittent course, a blood culture was made in which streptococci were obtained in pure culture. The internal jugular vein was ligatured and resected, and the lateral sinus was found to contain a septic thrombus some 2 inches long. On removal of this with obliteration of the sinus and administration of antistreptococcus serum the patient made a complete if tardy recovery.

Dr. H. COTTER presented a case of separation of the upper humeral epiphysis without displacement, and with an almost negligible history of injury. A radiogram was shown in illustration of the condition which was remarkable in that symptoms of pain and a coarse crepitus were first complained of two months after injury, and were possibly due to organisation of an effusion into the joint capsule.

Dr. R. C. CUMMINS demonstrated two cured cases previously shown before treatment had been instituted. They were, respectively, kerion of the beard treated with a mercurial ointment and staphylococcic vaccine, and a lupoid syphilide of the circumoral region.

Dr. N. MARSHALL CUMMINS presented a case of congenital defect in the ventricular septum. This was remarkable in that the patient was 30 years old, had never complained of cardiac distress, and had never been ill in his life. Cyanosis, polycythæmia, left ventricular hypertrophy, and a loud systolic murmur with maximum audibility at the fourth left interspace radiating into the neck, arms, and over the chest posteriorly, were all present.

Messrs. William Heinemann (Medical Books), Ltd., announce the forthcoming appearance of "Insulin in General Practice," by Dr. A. Clarke Begg, written entirely from the clinical standpoint.

Rebiews and Notices of Books.

PSYCHO-ANALYSIS.

A Critical Examination of Psycho-Analysis. By A. WOHLGEMUTH, D.Sc. Lond. London: George Allen and Unwin. 1923. Pp. 250. 10*s.* 6*d.*

EXCEPT for the work of MacCurdy and Rivers, there has been little effective criticism of psycho-analysis, and the student will open Dr. Wohlgemuth's book with the expectation of finding help in sifting the wheat from the chaff. The author soon settles down to consider fundamental questions and asserts that to talk about psychic facts before and after the stage of "awareness" is surely nonsensical, for the essential of a psychic fact is just this awareness. But many observers have found themselves obliged to assume that mental processes take place without the subject being aware of them, and the author's dismissal of this assumption as nonsensical is a *petitio principii*, though he tells us that psycho-analysts produce not a shred of proof, only assertions. One seeks for evidence that he has followed the same methods that these observers have followed, but, unfortunately, it is not easy to tell when he is "guying" the methods and when he is producing evidence meant to be taken seriously. He attempts by introspection to discover within himself particular tendencies which Freud claims to be present in every normal man, and on failing he remarks that Freud and his followers will retort that the experiments merely prove that no such tendencies are *conscious* in him, which is precisely what the experiments do prove. Since psycho-analysts postulate that such tendencies cannot be discovered by unaided introspection, the experiments have little bearing upon the subject and are not strengthened by the addendum that "their psycho-analytic method merely discovers in the patient what the psycho-analyst has been putting there himself," which is another *petitio principii*. The clinical experience of the results of the revival of lost memories, a method which as applied to war cases led many workers to accept the theory of the unconscious, is dismissed by a comparison with Mesmer's "salutary crisis" and the statement, without references, that "some authorities have pronounced themselves against this method in no equivocal manner."

There are, as would be expected from a psychologist of Dr. Wohlgemuth's standing, many sound criticisms to be found in the book. Some of the mystical and fantastic developments of psycho-analysis provide the author with points for effective attack, and he is not slow to detect important inconsistencies between the opinions of Freud and of Ernest Jones, his well-known disciple in this country. But he sets out to prove too much. It is too late in the day to say that psycho-analysis is a confidence trick, or that psycho-analysts are moral voyeurs, and the joke about psycho-analists on pp. 205 and 224 has lost its freshness. The book may afford pleasant reading to those who like to see psycho-analysis smitten hip and thigh, but it is not a sober and dispassionate examination of Freud's teachings.

Psycho-Analysts Analysed. By P. MCBRIDE, M.D., F.R.C.P.E., F.R.S.E. With Introduction by Sir H. BRYAN DONKIN, M.D. Oxon., F.R.C.P. London: William Heinemann (Medical Books) Ltd. 1924. Pp. 142. 3*s.* 6*d.*

Dr. McBride submits psycho-analysis to such criticism as he considers it to merit and arrives at certain conclusions, the first two of which are: that the whole scheme rests upon pure hypothesis or a series of hypotheses, and that these hypotheses "are so improbable as to vitiate their use as legitimate premisses." Upon these conclusions it follows naturally that it is unjustifiable to deduce from the hypotheses a method of treatment, and that, where this has been done, no evidence of success is forthcoming. There is nothing more important for the progress of medicine than submission of medical theories to criticism, but we do not find in this short series of chapters the broad outlook or unbiassed attitude which makes such criticism helpful. With other of the conclusions to which readers are invited to assent we could agree or partly agree, or from them could differ to a greater or less extent, without finding ourselves compelled to condemn in uncompromising language the practice of psycho-analysis. Certainly this practice has been exploited by some in an unworthy manner, but we feel that the author of "Psycho-Analysts Analysed" has entirely failed to demonstrate that no good has or can ever emerge from it.

NUTRITION.

Nutrition and Clinical Dietetics. Third edition. By HERBERT S. CARTER, M.A., M.D., Assistant Clinical Professor of Medicine, Columbia University, New York; PAUL E. HOWE, M.A., Ph.D., Associate, Rockefeller Institute for Medical Research; and HOWARD H. MASON, A.B., M.D., Associate in Diseases of Children, Columbia University. Philadelphia and New York: Lea and Febiger. 1923. Pp. 731. $7.50.

THE third edition of this excellent American work on dietetics has several improvements and additions. Much has been added in the chapter on Vitamins, which has been brought thoroughly up to date, while the discussion of the feeding of children has been enlarged to include the results of the recent critical survey of the subject by Holt and Fales in the United States. Recent work in connexion with the investigation of rickets and an account of Pirquet's "nem" system of feeding have also been included. In the section on Clinical Dietetics there is an interesting discussion of the subject of the ketone-antiketone properties of foods in their relation to diabetes.

Nutrition: The Chemistry of Life. By LAFAYETTE B. MENDEL, Sterling Professor of Physiological Chemistry, Yale University; Research Associate of the Carnegie Institute of Washington, D.C. Yale University Press. London: Humphrey Milford, Oxford University Press. 1923. Pp. 150. 14*s.*

THIS charming little book, the subject-matter of which formed the Hitchcock Lectures delivered at the University of California, will be welcomed by a large number of readers. The author is one who speaks with authority on this subject, and has dealt with it in an entertaining manner. The historical matter will for the most part be new to many, and serves to show how greatly and how rapidly the subject has developed. There are five chapters, the first is a retrospect, the second deals with the importance of "little things" in nutrition, the third with the vitamins, the fourth with the protein factor in nutrition, and the last with the energy problem in nutrition. The book is logical, the story is well sustained, and the style interesting, while good illustrations are numerous. Our congratulations to the author on a really excellent book.

DISEASES OF THE EAR.

Third edition. By PHILIP D. KERRISON, M.D., Junior Aural Surgeon to the Manhattan Eye and Ear Hospital. London and Philadelphia: J. B. Lippincott Company. 1923. Pp. 614. 35*s.*

THE publication of a third edition of this book within three years of the appearance of the second edition is proof of its popularity, which is well deserved. It is a model of what a text-book should be, for it contains a careful and thorough description of examination methods, providing elementary knowledge which the student should and the practitioner must possess, and gives details about the more obscure conditions which the specialist requires. In this edition there is but little change

in the substance of the work. A new and valuable chapter has been added on tumours of the eighth cranial nerve, based chiefly on Prof. Cushing's series of cases. The recent work on the otolith apparatus by Magnus and de Kleijn is just mentioned; a short abstract, sufficient to indicate its scope, would have been welcome. On the subject of cochlear function Wrightson's theory of audition and Gray's theory of maximum stimulation now receive mention, and, under the ætiology of otosclerosis, also Gray's degeneration theory.

The book is well illustrated, and is one of the best text-books on the subject we have seen.

TUBERCULOSIS.

Pulmonary Tuberculosis: its Diagnosis and Treatment. By JOHN GUY, M.D., D.P.H. Camb., F.R.F.P. & S. Glasg., F.R.C.P. Edin. Edinburgh: Oliver and Boyd. 1923. Pp. 307. 16*s*.

THIS book is intended primarily for the student, but the author hopes it may be of some use to the practitioner wishing to refresh his knowledge. It should fulfil both purposes well, although the practitioner may, perhaps, find the chapters on treatment comparatively short. But the author is well advised in devoting so large a section of his book to diagnosis, and the various means by which the disease can be detected early. The practitioner will often find that early diagnosis and simple rest treatment will save the patient from the need for the tinkering and symptomatic treatment the advanced consumptive is usually given. It is a sign of the times that the treatments to which the author gives most prominence are sanatorium treatment and artificial pneumothorax—measures neither of which comes, as a rule, within the sphere of the practitioner. He will assuredly again come into his own when he diagnoses the disease before gross changes occur.

With regard to tuberculin, the author does not consider the case for it to be proven, and he notes that the present consensus of opinion is against it. There is nothing so important in the diagnosis and treatment of tuberculosis as the scientific use of the clinical thermometer, and it is disappointing to find the author to be vague in his references to temperatures. On p. 227, for example, he writes: "If fever be present, and the temperature reach 100° F. in the morning, this period in bed should be extended indefinitely." On the next page he writes: "In sanatorium practice it is an almost invariable rule that a patient with either a morning temperature of 99° F. or an evening one of 100° F. (rectal) should rest all the following day." Readers unfamiliar with sanatorium treatment might assume wrongly from these words that if the temperature were a few tenths below the figures given, rest in bed was not indicated. In the chapter on Difficulties of Diagnosis he is to be congratulated on his condemnation of the authority who "plumps for" a diagnosis of tuberculosis on inadequate evidence. He gets the credit for early diagnosis, but many a non-tuberculous person struggles for the rest of his life under the stigma of tuberculosis. The author's advocacy of employing all the most searching modern diagnostic methods is most timely, and in this respect, as well as in many others, his book should prove of value.

Rules for Recovery from Tuberculosis. Fourth edition. Thoroughly revised. By LAWRASON BROWN, M.D. Philadelphia and New York: Lea and Febiger. 1923. Pp. 217. $1.50.

THIS is an old friend. Several changes have been introduced, vitamins being briefly discussed, and several new suggestions being made in the chapter on foods. Throughout the book numerous minor amendments have been made in an attempt to keep it abreast of modern knowledge. But there are no revolutionary changes, and this is all to the good, for the earlier editions have been most excellent. Ostensibly, this book is for the guidance of the patient, but were every physician to study it with the attention usually reserved for larger and more pretentious works, the standard of treatment of tuberculosis would undoubtedly be raised. The author possesses the rare combination of facility of diction and the capacity to condense important information, and the reader should be careful not to skim the book, failing to note that there is some profound truth in almost every sentence.

SCIENCE AND THE FUTURE.

Dædalus. By J. B. S. HALDANE. London: Kegan Paul, Trench, Trübner and Co. 1924. Pp. 93. 2*s*. 6*d*.

"WONDERFULLY clever and I daresay mostly true," as Darwin said when he had been reading Herbert Spencer.

In this bright and witty book the Reader in Biochemistry in the University of Cambridge exercises an admirable faculty of being serious without being solemn in telling of his dreams of what scientific progress will bring. Chemistry and physics will proceed on their way; cheap power will be collected by windmills and stored as hydrogen made electrolytically from water; food will be made in factories, carbohydrates from cellulose, proteids from coal and free nitrogen; space and time will be minimised in various directions. But the future really lies with the biologist, who alone can make man what he should be—body, soul, and spirit. We are at present almost wholly ignorant of biology which makes us too modest in our estimates of what it may achieve in the future: once it can disentangle generalisations of the order of those which have lately been tumbling over one another in molecular physics we shall realise what its potentialities are. As a small example the author gives us the production of children in vitro: a good ovary will produce an egg a month under suitable conditions, and most of them can be fertilised and grown successfully in artificial solution for nine months and then brought out into the air. These ectogenetic children will restore the population depleted by the success of preventive campaigns, and the ova and spermatozoa can be so selected that the very best products can be guaranteed. So shall science ultimately achieve its aim—that man should conquer space, time, and matter, and then his body and finally the evil in his soul. "The open secret my door discloses Is fairer than God or woman or roses," as the author says elsewhere.

Mr. Haldane's essay can be heartily commended for general reading, even to those who saw its substance in the *Century Magazine* for August, 1923—a previous publication which does not seem to be mentioned in the present version.

THE ELEMENTS OF PUBLIC HEALTH ADMINISTRATION.

By G. S. LUCKETT, M.D., Director of Public Health, New Mexico; and H. F. GRAY, B.S., M.S., Chief of Division of Sanitary Engineering and Sanitation, New Mexico. Philadelphia: P. Blakiston's Son and Co. 1923. Pp. 460. $3.

THE authors explain that, in the autumn of 1919 they were called upon to help in the construction of an entirely new State health department, where no organised central health agency had previously existed. This book is in no wise intended to supplant the more comprehensive text-books, but rather to furnish a handy manual of practical suggestions for the use of the practising physicians appointed as part-time health officers in the various districts, many of whom had been necessarily out of touch with modern health agencies for years. We should imagine that the book fulfilled its original purpose admirably, and will prove of practical value to many new health officers of small communities. To British readers the book will prove of interest, as showing the difference in methods which have to be adopted in such a country as New Mexico. For example, there is no mention of hospitals for infectious disease or sanatoriums. Part I

deals with public health administrative measures. Part II. deals with a large number of preventable diseases, including many which are met with in the Southern States, but which cannot, as a rule, concern the British medical officer of health; these include Malta fever, hookworm disease, beri-beri, pellagra, Rocky mountain spotted fever, and dengue. Part III. consists of appendices on various subjects, such as a plan of county health work, instructions to public health nurses, a curriculum for midwives, a dairy score card, the technique of the Schick test, disinfection and delousing methods.

No doubt the British sanitary officer will find much of interest in this volume.

CYTOLOGY.

The Physical Basis of Life. By E. B. WILSON. New Haven: Yale University Press. 1923. With 20 figures in the text. Pp. 51. 7*s.*

THIS is the first William Thompson Sedgwick memorial lecture given in the Massachusetts Institute of Technology to commemorate that distinguished and loved biologist and hygienist. It is a survey, in general terms, and addressed to a wide biological audience, of the present state of knowledge of cell structure and its significance. Prof. Wilson is a convinced mechanist, though he is not concerned to argue the matter here: he has taken the title of a famous address of Huxley's which, as he says, put a spell on him when he was a college student, and he points out how the "protoplasm" which was then the physical basis of life has since been dissected with the discovery of a great variety of organs, first mostly in the nucleus, in more recent times in the cytoplasm too. He might as well have called his lecture "The Cell in Development and Inheritance"—a book which has enthralled many an undergraduate, and which has unfolded in such a wonderful way of late at the hands of his colleagues at Columbia. We are glad to see that a new edition—about 20 years overdue—is in preparation.

SURGICAL "DON'TS" (AND "DO'S").

By C. HAMILTON WHITEFORD, M.R.C.S., L.R.C.P., Hon. Surgeon to the Plymouth Infirmary. London: Harrison and Sons, Ltd. 1923. Pp. 46. 3*s.*

THE sprightliness of the title of this booklet does not get lost in any of the ten short chapters it contains. They have been published elsewhere from time to time during the past 13 years, the first being a paper read in 1910, the last being written in 1923. Many of the "Don'ts" are useful, isolated scraps of advice, but there are a few "Don'ts" which recur throughout the booklet with certain variations, and which give a clue to what are the author's pet aversions. "Don't overrate the importance of manual dexterity." Further on he urges his readers not to confuse the operator with the surgeon. The operator's "sole asset" is his manual dexterity; he is happy only when operating, and is a distinct danger to the public. The surgeon, on the other hand, knows when not to operate. "The war has produced a copious crop of operators, but has not correspondingly increased the supply of surgeons." Some of the "Don'ts" verge on the superfluous and are hardly polite. "Don't have anything to do with secret commissions," is a warning which, like Do not commit adultery, might be taken for granted. There is one curious "Don't." It runs: "Don't accept the position of honorary surgeon to a doctor and his family, when you are never asked to attend to the surgical needs of his patients. Actions speak louder than words, and the implication, obvious and illogical, is that you are considered capable of undertaking gratuitous attendance on the doctor and his family, but incapable of treating his paying patients." The ethics of this advice are rather doubtful, but perhaps the author could a tale unfold to justify this. Most of the advice given is sound and some is witty, and the recently qualified medical student will find here much knowledge as well as mirth.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

VII.—ACTIONS FOR DAMAGES: ERRORS OF TREATMENT.

BY HUGH WOODS, M.D., D.P.H.,
GENERAL SECRETARY, LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

. . . . being in,
Bear't, that the opposèd may beware of thee.
—*Hamlet.* Act I. Sc. 3.

WHEN every proper precaution has been taken against the risk of claims for damages founded on alleged wrong diagnosis, there still remain the risks that arise out of accusations of wrong treatment. The same condition or ailment is by no means always treated in the same way by different practitioners. Modes of treatment apparently quite different may be equally good, or opinion may be equally divided as to which is the best, or the mode of treatment approved by a distinct minority, or even by a single individual, may in fact be the best. Nevertheless, a judge and jury, who know little or nothing about it, are apt to regard any departure from the recognised routine treatment as being due to careless neglect to observe the ordinary rules of medical practice, and if a number of medical witnesses all admit that the treatment was not that which they would themselves have adopted, it may be unhesitatingly condemned even though quite suitable and quite carefully and deliberately adopted.

Safeguard of Consultation.

When a case presents special difficulties, or appears likely to have an unfavourable result, it is a great safeguard to call another doctor into consultation, and preferably one of high standing in the profession, or a specialist in cases of the kind. Here again the question of expense may have to be considered, and if it is objected to, the medical attendant will be well advised to provide himself with clear evidence that he had advised the calling in of a consultant, and that the responsibility for its not being done rests with the patient or the responsible relatives. Where medical assistance is desirable it should be asked for. If an operation is undertaken single-handed, and some mishap occurs which might conceivably have been avoided if another doctor had been present, the operator may be regarded as guilty of negligence in not insisting on medical assistance before undertaking the operation.

The Giving of Anæsthetics.

It is seldom right to attempt to operate and anæsthetise at the same time. In midwifery cases it is not uncommon for a doctor to administer an anæsthetic and to instruct a nurse to continue the administration while he uses the forceps or performs some obstetric operation, and it is sometimes not easy or perhaps practicable to do otherwise; but if any mishap occurs the doctor will run the risk of being mulcted in damages unless he can prove that there would have been greater danger in waiting until medical assistance had been procured. When there is no need for haste, and the operation can be safely and properly deferred till a qualified anæsthetist can be obtained, it is not advisable to undertake the dual responsibility.

Operation in Presence of a Third Person.

Again, it is seldom wise to perform even the more trivial operations without some responsible person being present. The experience of a patient fainting, or collapsing seriously under an operation, with imminent danger of sudden death when no one else

is present, will make a doctor very reluctant to place himself in a similar position a second time. It is desirable to have notes of cases dealt with, but in a busy general practice it is exceptional for any record to be kept of anything beyond the visits and consultations and the medicines prescribed. Prescriptions should always be recorded, especially when any poisonous drug is prescribed, whether the doctor dispenses his own medicines or not.

Delayed Complaints.

It quite often happens that no complaint of any kind is made of the treatment of a patient until, perhaps after the lapse of a year or two, the patient is informed that steps will be taken to enforce payment of the fees which remain unpaid notwithstanding the frequent rendering of the account. Then grave charges of negligence or wrong treatment are launched and payment is refused with a threat of action for damages. The doctor tries to recollect the case, and searches for any record of it, but the whole final result often amounts to a strong personal conviction that there is no foundation for the accusations, and to nothing more. Under such circumstances it needs not a little courage to go into court, and the unscrupulous patient, quite appreciating the situation, knows that he has a very good chance of escaping payment although he has no grounds whatever for his complaints. If the doctor does not sue for his fees it may encourage his patient to venture on a speculative action for damages, or he may content himself with boasting that he accused the doctor of negligence and refused to pay him and that the doctor was afraid to go into court.

Exaggerated Importance of Many Claims for Damages.

Threats of actions for damages against doctors are very common, and although they should be taken seriously they ought not to be feared in the great majority of cases. The object of such threats is usually to avoid payment of fees, and sometimes it is a comparatively safe method of attempting to blackmail. A firm attitude is essential, and great care should be taken not to spoil a good case by hasty replies inspired by indignation or alarm. Many doctors have an exaggerated idea of the harm that may be done to their practices by actions for damages. In many cases, even when damages are awarded against them, the advertising influence of a case of public interest and the sympathy aroused among their friends and neighbours may more than counterbalance any ill-effects, if the evidence does not disclose clearly reprehensible conduct, or make them appear incompetent, ridiculous, or contemptible. What makes actions for damages pecuniarily unsatisfactory is the fact that in most of the cases the plaintiff, when he loses his case, does not pay the defendant's costs, and consequently a successfully defended action involves heavy loss to the doctor, although, of course, such loss is lighter than if he had lost the case. The anticipation of such a result is not unlikely to weigh too heavily with a medical practitioner of scanty means if he has to defend himself, and it may lead him to yield to unjust demands to the encouragement of dishonest persons who seek to prey on medical men. In modern times it is to be feared that the law courts occasionally afford an effective means of dishonestly extorting money, because it is often cheaper to buy off a plaintiff than to defend an action successfully and pay the heavy costs of a barren victory.

Claims Suitable for Reasonable Settlement.

There are claims for damages which should be honestly admitted, but not in such a way as to enable an unscrupulous person to use the admission for what is morally, though not legally, blackmailing. The human machine is not so perfect that it does not occasionally fail to avoid accidents which might be avoided, and although there may be no moral culpability, yet it seems only fair that the person whose failure has caused the accident should bear the consequences, as far as is reasonable, rather than the person who is undoubtedly quite blameless. In such cases it is both honourable and prudent to settle a claim on reasonable terms, which should include on the part of the claimant an admission that there was nothing in the mishap for which liability is accepted which is discreditable to the doctor professionally. Care should also be taken that no loophole is left for subsequent claims on various pretexts which might be put forward after denial of legal liability had been rendered impracticable. When extortionate demands are persisted in they should be resisted if possible. In some cases, even when it is doubtful if there is any legal liability, but where the claim is a genuine one and the patient has in fact suffered damage, it may be advisable generously to give a "solatium" if it is accepted in a proper spirit and as a gratuitous donation, all legal claims being effectively withdrawn.

INSTITUTIONAL MEDICAL OFFICERS AND INCOME-TAX ASSESSMENT.

THE letter of the General Secretary of the Medical Defence Union, which appeared in our issue of Feb. 9th, proves the necessity of carefully scrutinising tax demands, a course recently emphasised in this column. The decision of the Special Commissioners that a medical superintendent, occupying premises by virtue of his office, is not liable to tax on the value thereof is simply an application of an established principle. In income-tax law a profit which is not cash, or capable of translation into cash, is not assessable upon the recipient, and the case of Tennant *v.* Smith (1892) is regarded as the leading decision on the point. In that case a banking company assigned to their agent as a residence a portion of their bank premises in respect of which they were assessed under Schedule "A." The agent was required to reside in the building as the servant of the bank, and for the purpose of the performance of his duties. It was then held that the value of the residence was not an emolument of office in respect of which the agent was chargeable with income-tax; and was not to be included in estimating the total amount of the agent's income for the purposes of a claim of abatement. Lord Watson said: "I do not think it comes within the category of profits, because that word, in its ordinary acceptation, appears to me to denote something acquired, and which the acquirer becomes possessed of to his advantage—in other words, money—or that which can be turned to pecuniary account." The Lord Chancellor said: "I do not deny that, if substantial things of money value were capable of being turned into money, they might for that purpose represent money's worth, and be therefore taxable . . . The thing sought to be taxed is not income unless it can be turned into money." The value of the house in such circumstances, therefore, is neither assessable on the employee nor should it be included in his return of total income. Neither is the value of board and/or lodging assessable, and it should be similarly excluded.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: *Parkin Prize.*—In terms of the bequest made to the College by the late Dr. John Parkin, Fellow of the College, a prize is offered for the best essay on certain subjects connected with medicine. The subject of the essay for the present period is on the Effects of Volcanic Action in the Production of Epidemic Diseases in the Animal and in the Vegetable Creation, and in the Production of Hurricanes and Abnormal Atmospherical Vicissitudes. The prize is of the value of £100, and is open to competitors of all nations. Essays intended for competition, which must be written in the English language, to be received by the Secretary not later than Dec. 31st, 1924. Each essay must bear a motto, and be accompanied by a sealed envelope bearing the same motto outside, and the author's name inside. The successful candidate must publish his essay at his own expense, and present a printed copy of it to the College within the space of three months after the adjudication of the prize.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 16, 1924.

INFLUENZA.

DEATHS from influenza in the 105 great towns increased from 236 to 367, and in London from 74 to 122, in the last week (ended Feb. 2nd) for which figures are available. The distribution of these deaths showed somewhat increased incidence upon the ages 45–65 as compared with the age-group 65 and upwards, but no increased proportion of deaths below 45—that is to say, no reversion to the 1918 epidemic type. The rate of increase slackened from 64 per cent., which was the increase in the week ending Jan. 19th over the previous week, to 54 per cent. Provisional figures for the week ending Feb. 9th suggest that although the absolute maximum of the epidemic has not yet been reached, the rate of increase appears to be slackening. The mortality in any one week, even in the most unfavourable conditions, will hardly be as severe as that of 1922. The greatest stress of mortality has so far fallen on London and certain coastal regions, particularly in the north-east. Thus, in South Shields deaths from influenza in the successive weeks have been 4, 14, and 24; in Newcastle-on-Tyne 1, 9, and 16. Clinical reports are consistent with the impressions derived from the mortality figures. Widespread epidemic influenza of a mild 3–4 day type has prevailed in Durham and Northumberland. An area including Bath, Gloucester, Weston-super-Mare, and Trowbridge has been widely affected by mild influenza, and there is some evidence of extension to the South Wales coalfield. In the north-west cases have been relatively few. There is complete concordance of opinion that severe and pneumonic complications are very rare. In Paris influenza is unusually prevalent, it is increasing in Switzerland, declining in Algeria and Mauritius. This is the position as it is seen by the medical officers of the Ministry of Health.

Every such recurrent wave of epidemic influenza raises the question of the relationship of these minor epidemics to each other, to sporadic cases, and to the great pandemics such as that of 1918–19. Up to the present the lack of any constant bacteriological findings has rendered it difficult to arrive at a conclusion as to these relationships, and almost impossible to decide whether the protean conditions—gastric, nervous, cardiac, pharyngeal, and pulmonary—grouped under the common head of "influenza" are really manifestations of the activity of the same pathogenic agent. Whether a patient suffers from a "cold in the nose" or from "influenza" is largely a matter of individual taste or temperament, and so many chronic and subacute disorders have according to the histories given by the patients started in an attack of "influenza" that a condition, real enough as an entity and vastly potent as an initiator of morbid processes, is perhaps now hardly receiving its due meed of attention as an ætiological factor. Some hope of escape from this chaos was offered by the investigations of Drs. P. K. OLITSKY and F. L. GATES, reviewed in our columns [1] a couple of years ago, and more recent work of these authors [2] holds out some prospect that in the future "influenza," from being the limbo of all undiagnosed acute conditions, may come to be an entity as sharply defined and as readily diagnosable as typhoid fever. This happy consummation, of course, depends on whether or not the work of Drs. OLITSKY and GATES is capable of being reproduced in the hands of other investigators. Time alone will show this; already some evidence apparently in support is to hand from Japan.[3] The position at the moment is that from the naso-pharyngeal washings of patients suffering from influenza in the 1918–19 pandemic the American workers were able to cultivate a minute Gram-negative anaerobic organism, growing freely on artificial media, capable of passing earthenware filters and named by them *B. pneumosintes*. By injecting this organism intra-tracheally into rabbits they were able to produce a condition not dissimilar from epidemic influenza and clinically manifesting itself by conjunctivitis, fever, and malaise; the blood showed a leucopenia. The uncomplicated condition was not fatal, recovery taking place in from three to six days. If killed during the course of the disturbance the lungs of the infected animals were found to show constant and characteristic changes, consisting of œdema, emphysema, hæmorrhage, and a slight degree of cellular infiltration. The intra-tracheal introduction of pathogenic organisms such as streptococci or Pfeiffer's bacillus while the lungs were in this condition rapidly led to the development of a fatal pneumonia of the "influenzal" type.

The occurrence of a small wave of epidemic influenza in New York some months ago offered an opportunity for ascertaining whether the *B. pneumosintes* was concerned in this in the same way as in the 1918–19 pandemic, during which it was first isolated. In the course of their previous work Drs. OLITSKY and GATES had been able to demonstrate that on injection of the organism into the blood-stream of rabbits agglutinins were developed; they further showed that similar agglutinins appeared in the blood of human beings inoculated with suspensions of the dead organism. In their recent investigations they were able to demonstrate the presence of agglutinins active against the 1918–19 strain of *B. pneumosintes* in the blood of all the patients examined. These agglutinins appeared as early as ten days from the onset of the disease, and seemed to reach a maximum by about the seventeenth day; they persisted for some months—at least five—but not indefinitely, as was shown by the fact that the blood of persons who had suffered in the 1918–19 or 1919–20 epidemic, but not since, was free from them. The agglutination titre was low; even with special buffering of the antigen it seldom went beyond 1 in 40 in injected animals and in the human cases a positive result at a dilution of 1 in 10 was taken as diagnostic. Antibodies were also demonstrable by a precipitin test. Granted that *B. pneumosintes* is confirmed as the ætiological factor in the influenzal entity—a matter concerning which Drs. OLITSKY and GATES make no dogmatic assertions—these agglutinin and precipitin reactions may prove of great value.

CREMATION AND THE CONCEALMENT OF CRIME.

IN a lecture on the Disposal of the Dead, with Special Reference to Cremation, recently delivered before the Royal Institute of Public Health, Dr. H. T. HERRING, who is the medical referee to the Golders Green and Woking Crematoria, dealt with various objections to the practice of cremation. While this now well-established practice has not yet entirely disarmed popular antagonisms which in part are based upon genuine religious feeling and in part upon ancient prejudices, its advocates are aware that they have to reckon with one substantial objection—namely, the fact that incineration of the body obliterates all traces of crime. Against this objection it may fairly be argued that the present system of the law of death certification, which we hope soon to see amended,[1] is so lax that a murderer is but little inconvenienced in obtaining the burial of his victim under the existing facilities. In all murder cases the criminal is anxious not only to conceal his own part in the death, but also to conceal the facts of death itself. Where this is the position, questions of the relative advantages of graveyard and crematorium are immaterial. In other cases—for example, in the series of murders by arsenical poisoning in recent years—it looks as though the criminal was sufficiently deterred from taking advantage of the method of cremation by the very stringent precautions which the State enjoins and the very searching interrogatories which the adoption of that method entails.

The Cremation Act of 1902, passed nearly 20 years after Mr. Justice STEPHEN had decided that cremation was not illegal, authorised the Home Secretary (or in Scotland the Secretary for Scotland) to make regulations as to the construction and inspection of crematoria and as to the conditions in which the burning of human remains may take place. The Home Office Regulations of 1903 prohibited cremation except in a crematorium of the opening of which official notice had been given. They forbade the burning of unidentified human remains or of the body of anyone who has left a written direction to the contrary. The necessary forms and certificates to be filled up are most elaborate. Apart from the simpler procedure where a coroner gives a certificate following the verdict of a coroner's jury, the requisite action is as follows. A form of application is filled up by the executor or nearest surviving relative; if anyone else is the applicant he has to give a satisfactory explanation of the reason why the executor or next-of-kin has not applied. Two medical certificates are required, one from the doctor who attended the deceased during his last illness and can definitely certify the cause of death, the other a confirmatory certificate by a specially qualified medical practitioner. Both the application (which has to be supported by a statutory declaration) and the former of the two certificates must give a specific answer to the question whether there is any reason to suspect that death was directly or indirectly due to violence, poison, privation, or neglect. The application and the two certificates are quasi-judicially examined by a specially qualified medical referee who can refer them back for further information. The medical referee is forbidden to allow cremation unless satisfied that the fact and cause of death are satisfactorily ascertained; if it appears that death might have been due to violence, an illegal operation, privation, or neglect, he must require a post-mortem examination; if the post mortem fails to reveal the cause of death there must be an inquest. Finally the medical referee may refuse cremation without stating any reason. These Regulations of 1903 have been recalled in some detail to show their reassuring character. In 1920 they were revised and re-issued, but only three modifications were found necessary. One of these alterations empowered the Home Secretary to relax the procedure in certain cases of death outside England and on certain conditions. Another allowed the Home Secretary to dispense with an inquest in certain cases. A third exacted more information from the medical attendant of the deceased. In addition to stating the primary and secondary causes of death as formerly, he is now obliged to say whether any other cause, and if so what, contributed to or accelerated death; his certificate also now includes a declaration in the widest terms that there is no circumstance of any sort known to him which makes cremation undesirable.

If anyone, reading the Home Office Regulations and the wording of the forms and certificates, thinks them insufficient for the purpose, he will still find it hard to imagine how they could be made more comprehensive. The burden of investigation is properly laid upon the medical profession; it has not been suggested that there has been failure to discharge the responsibility. The ingenuity of criminals and the fallibility of human beings make it impossible to claim that the machinery eliminates all risk that cremation will allow crime to go undetected. But, short of repealing the Cremation Act and making cremation entirely illegal, it is difficult to devise safeguards more satisfactory than those which at present exist.

[1] See the summary of the proposed Bill in THE LANCET of Jan. 12th p. 92.

PHYSIOLOGICAL EFFECTS OF RADIUM AND X RAYS.

THE scanty literature of this subject has been enriched lately in a paper by Dr. J. C. MOTTRAM and Dr. W. CRAMER in the *Quarterly Journal of Experimental Physiology* (Vol. XIII., Nos. 3 and 4), and by a series of articles in Vol. VII. of the Collected Reprints from the George Williams Hooper Foundation for Medical Research, by Mr. S. L. WARREN, Dr. G. K. WHIPPLE, and Dr. I. MCQUARRIE of California University. The first paper deals with the effects of exposing rats to the beta and gamma rays of radium, the special points under investigation being the effect upon metabolism and tumour growth and some special action upon the testis and pituitary. When rats were given comparatively small doses of radiation, repeated over 40 days, they became fatter and grew inoculated sarcoma less than controls; this is confirmatory of the general findings of RUSS, CHAMBERS, and SCOTT in the case of rats and of SUGUIRA and FAILLA in the case of mice, but the present authors observed the very significant facts that in the irradiated rats there was atrophy of the seminiferous tubules with increase of the interstitial cells, as well as abnormal appearances in the pituitary gland. On irradiating the testis only, the rest of the animal being protected, atrophy of the testis occurred, yet the weight of the animal increased, this increase being attributed by the authors to the formation of fat. On giving a relatively large dose of radiation to the head of the animal only, no variation from the normal was found, and the conclusion seems justified that the pituitary changes previously observed were secondary. A large part of the paper is devoted to the histological appearances of the various organs in question under various experimental conditions. A significant finding was that atrophy of the testis brought about by irradiation is accompanied with hypertrophy of the interstitial tissue. Dr. MOTTRAM and Dr. CRAMER endeavour to correlate the inter-

relationship between testis and pituitary; in particular they refer to the conclusion of other writers that the change in the anterior lobe of the pituitary following castration is due to the withdrawal of an internal secretion attributed to the interstitial cells of the testis. They point out that this cannot be the case as the effect in question sets in after irradiation, when the interstitial cells are present or even increased. They conclude therefore that the pituitary change must be due to absence of seminal epithelium. Their observations show that the two component tissues of the testis, the spermatogenic and the interstitial, have distinct and independent effects upon the organism, that of the interstitial cells being the more profound. Even in the absence of spermatogenic tissue they provide an internal secretion which produces changes in the intermediate and nervous portions of the pituitary. Possibly other endocrine organs are affected also and contribute to the metabolic changes noted. In an appendix Dr. CRAMER describes cells in the pituitary of the rat which do not appear to have been noticed before; he calls them lipo-neurocytes. The authors have not found them in the cat, dog, rabbit or guinea-pig.

The American studies are on X ray intoxication and have a practical bearing upon the treatment by means of penetrating rays, especially where irradiation involves exposure of the abdomen. Similar doses of X rays over thorax and over abdomen produce very different effects in dogs. A dose which, directed over the thorax, gives no clinical evidence of intoxication ensures the death of the animal on the fourth day if given over the abdomen. Histological examination showed that the epithelium of the small intestine from the pylorus to the ileocæcal valve is highly sensitive to X rays. The authors attribute the intoxicating effects which follow deep irradiation to necrosis of this epithelium. The second article compares the rates of autolysis in many of the tissues of the dog under normal conditions and after doses of radiation. In general an increased rate of autolysis was found in irradiated organs, a point of special interest being that in dogs the secretory crypt of epithelium of the small intestine autolyses first and the epithelium of the villi last, the reverse being true under normal conditions. Finally a study of renal function after X ray exposures is of a reassuring character, for the authors find that the epithelium of the kidney is much more resistant to X rays than is the epithelium of the small intestine. "Our experiments give no support," the authors categorically state, "to the current belief that an X ray nephritis may be produced by direct or indirect action of the hard Rontgen rays." Large doses were given directly over the kidney, and although a slight lowering of renal function lasting a few days was noticed, no histological changes could be discovered in the kidney itself.

THE PROTECTION OF YOUTH.

THE first Bill[1] of the new Government has been ordered by the House of Commons to be printed, and has for its general object the consolidation, extension, and amendment of the Children Acts 1908 to 1921; it is presented by Mr. C. G. AMMON, Parliamentary Secretary to the Admiralty. The Bill contains enactments relating to offences against the person where the age of the subject is under 16, makes provision among other things to extend and amend the law of homicide in connexion with childbirth, and goes with particularity into the subject of infant life protection. Many new offences are created by the proposed enactments, but one of the final clauses provides that notwithstanding anything in the measure, no persons of or over the age of 16 years and under the age of 19 years shall be liable to be kept in penal servitude: the greater rigours are kept rightly for the older offenders. The first part of the Bill, which is to have force also in Scotland, extends the law of homicide to the protection of every child partly issued from the womb of its mother, while the criminal causation of the death of an unborn child will amount to felony punishable with penal servitude, or by imprisonment with or without hard labour. Enactments in the Criminal Law Amendment Acts of 1885 and 1922, with respect to sexual offences against young girls, are re-enacted with amendments and fresh provisions, while boys under 16 are also protected from the lascivious actions of women and girls over the age of 18 years. The purpose of these provisions is obvious and admirable, but medical men will see that, where their evidence is required, it may often be difficult to speak with certainty, while it is undoubted that the public will undergo added risks of blackmail, a crime now dangerously prevalent. For these reasons certain of the proposals will undergo criticism when the measure is debated in Parliament, but the evils against which the law is being directed are of so gross a nature, and have for so long been demanding abolition, that we hope to see the remedies proposed arrive in substance, even if with modification.

The number of children who will require care and maintenance, when separated from parents or guardians who have shown themselves unworthy, will be increased by the new legislation, and the second part of the Bill, in detailing the measures to be taken for infant life protection, places great responsibility upon the Minister of Health. All persons undertaking, in return for payment or reward, direct or indirect, the care and maintenance of orphans or infants who have been separated from their parents, have to make their position good to the local authority, that is to the county or borough council, and their selection will have to be justified to the Minister of Health. To be certain that adequate shelter and succour will be afforded to the children the local authority must appoint persons of either sex to be infant protection visitors, with the duties of keeping watch from time to time over the infant charges and the premises on which they are kept; while philanthropic societies, performing similar duties in respect of the infants, will be obliged to furnish reports of their procedure to the local authority. Great liberty of action is given to the local authority with regard to appointing these visitors, either as individuals or as a committee, and there is no reason to suppose that every care will not be taken; but it is obvious that the necessity for medical advice, both in choosing the visitors and defining their activities, will often be valuable. No visitor will be useful who is not kind, but it is necessary that the visitors should also be wise and tactful, for it is proposed to give them considerable discretion in discharging their duties. It will be necessary for the local medical practitioners to be familiar with the visiting machinery. In the routine of their professional duties they will be in charge of any case of sickness that may arise; by communication with the medical officers of the local authorities they can get into touch both with those who are responsible for the selection of the visitors, and with the Minister of Health to whom this selection has to be justified. For these reasons the appointment of a visiting committee rather than the selection of individual visitors appears to us quite important: for in a committee some can supply the tact and some the discretion, while all, it may be hoped, will furnish the kindness. The proceedings of such a committee could be made known in a regular way to the medical men of the district, when help could be obtained in many directions, the medical officers of health coöperating with the practitioners to supply it. We are taking it for granted that, either individually or through such committees, full use will be made of much excellent service now proceeding directly or indirectly along the indicated lines.

Annotations.

"Ne quid nimis."

THE PRICE OF INSULIN.

THE story of insulin has made one of the brightest chapters in modern therapeutics, clouded only by the fact that it has not been possible to distribute the boon which medicine has provided equitably as between the rich and the poor. At first the limitation of the available supply made it impossible for any but a well-to-do diabetic subject to use the remedy for "a carbohydrate jag" (the phrase has been used in scientific circles), and the lesson has since been taught that even the most lavish use of the preparation cannot dispense with the restriction of diet and the temperate habit of life which must be observed by all diabetic subjects. After a period of general disappointment, during which people of moderate means were unable to obtain the remedy in the necessary quantities for themselves or their dependents, there have followed the happier events of far larger production, lowered prices, and in certain circumstances gratuitous supply. The Province of Ontario, for example, is providing its diabetics with free insulin on the certificate of their medical advisers.

We print this week a preliminary communication from the Bio-Chemistry Department of the Middlesex Hospital, which opens the possiblity for a *substantial* reduction in the price of insulin. This will occur if the process of manufacture can be quickened, and if alcohol can be dispensed with in the preparation of the remedy. The change may then be dramatic, and to medical men it will be a pleasing reflection, if the work proves successful, that it has been carried out at a scientific department of one of our voluntary hospitals, with the collaboration of the Medical Research Council, and has been placed immediately and without reserve at the disposal of the community. It is one more example, if example were needed, of the essential soundness of the voluntary hospital principle, for the voluntary hospital is here seen to be coming to the aid of that class which lies between the persons who are fit objects of medical charity and those to whom the price which they pay for medical service is of little matter.

"SOME ENCOURAGEMENTS IN THE SURGERY OF MALIGNANT DISEASE."

ALL surgeons of experience have had occasional unexpected successes in the surgery of malignant disease but these have been overshadowed, perhaps too much, by the number of failures; for failures so often occur in those very cases in which the prognosis has appeared most hopeful. It was, therefore, a happy thought of Mr. G. Grey Turner to give an address last week to the Section of Surgery of the Royal Society of Medicine on the subject of encouragement. In this address Mr. Turner described a large number of cases of proven malignant disease operated upon with such success that they were alive and well five, ten, or more years later, or died after a considerable interval of apparently perfect health from some other malady. While many of these cases were examples of carcinoma of the colon, a form of comparatively low malignancy, where the anatomical conditions often lend themselves to an "ideal cancer operation," there were examples of success in other and more malignant tumours and even after metastasis had occurred. In the discussion that followed, other surgeons were able to recall some very striking cures of malignant disease by surgery, perhaps the most arresting being that told by Mr. James Berry of a case of periosteal sarcoma of the bones of the forearm, alive and well 33 years after amputation through the arm by Sir T. Smith. Mr. J. E. Adams knew of a case of sarcoma of the intestine first operated upon in 1912; further operation two years later revealed extensive secondary dissemination in the peritoneum, yet the patient was now alive and well, had married, and was at present an expectant mother. The question of "spontaneous cure" was raised by Mr. H. W. Carson in whose practice such an event had occurred. From Mr. Turner's address and the discussion two facts emerge. First, that a bold surgeon may by heroic measures occasionally save an apparently hopeless case of malignant disease; and secondly, that local recurrence or even metastasis after a primary operation is not an absolute bar to the successful issue of a further operation. While the statistics of the surgery of malignant disease remain as depressing as they are, these two facts should be kept in view before a hopeless prognosis is delivered.

THE ULTIMATE RESULTS OF TREATMENT BY ARTIFICIAL PNEUMOTHORAX.

BURIED in a gigantic work,[1] to which many authors have contributed, is an article by Prof. U. Carpi on the ultimate results of treatment by artificial pneumothorax. His paper is opportune, for the critics of this treatment have lately shifted their ground, admitting that the immediate results may be excellent, but arguing that it is only palliative and incapable of achieving permanent arrest of the disease. In addition to reviewing his own results after a fairly long observation period, Prof. Carpi has collected the statistics of Dumarest and Murard, L. v. Muralt, Saugman, Tiderström and Esther Carling. Prof. Carpi's own cases number 129, of which 120 were cases of pulmonary tuberculosis. In 28 cases pleural adhesions prevented the collapse of the affected lung, and within a year 20 of these 28 cases had terminated fatally. These 28 cases he uses as controls—the standard by which he judges the efficacy of artificial pneumothorax treatment in the 92 patients in whom a pneumothorax could be induced. Only 38 of these patients died during the first year of observation. In 33 cases definite recovery was effected, and in 20 complete restoration of fitness for work could be claimed. In other words, more than 21 per cent. of the patients thus treated were enabled to take up their work as before, whereas only three of the 28 controls could do so. In many cases the recovery effected by an artificial pneumothorax had been maintained for seven to ten years, and it was evident that this recovery was anatomical as well as clinical—i.e., that the condition of the lungs was like that found post mortem in cases of healing of tuberculous lesions by fibrosis. Prof. Carpi reproduces numerous illustrations showing the changes which the collapsed lung undergoes, but in the end he admits that the mode of action of a pneumothorax is not that simple process which some would have us believe. The fact that laryngeal disease and even renal disease may clear up after a pneumothorax has been induced suggests that the process is not a strictly local one, but one with far-reaching changes in the specific defensive mechanism of the body as a whole.

NATIONAL HEALTH COMMITTEES.

IN a refreshing address[2] to the London Centre of the National Association of Trade Union Approved Societies, Mr. C. A. Clark, clerk to the West Ham Insurance Committee, spoke of the long-forgotten function of national insurance committees in the sphere of public health. It was laid down in the original 1911 Act that, in addition to their other powers and duties, insurance committees should make such reports on the health of insured persons within the area as the Insurance Commissioners might prescribe. Few insurance committees have taken up the production and publication of health reports, partly owing

[1] Handbuch der gesamten Tuberkulose-therapie. Edited by Prof. Ernst Loewenstein. Vol. II. Vienna: Urban and Schwarzenberg. 1923. Pp. 1045–2025. Swiss Fr.33.75.

[2] National Insurance Gazette, Jan. 12th, 1924, p. 20.

to the absence of trustworthy ready-to-hand data and partly from fear of trenching on the ground of the public health authority. But Mr. Clark points out with justice that these committees have already much material at hand relating to health causes and effects, some of which might throw light on housing and other health problems, and he exhorts the committees to take their share in the strenuous and continuous effort which will be necessary if present housing conditions are to be ameliorated. He would like the committees to disseminate information on the few simple health rules of real value to the community. Here again the statutory obligation of insurance committees to "make provision for the giving of lectures and the publication of information on questions relating to health" has been almost completely overlooked. Expenditure by these committees upon lectures has been restricted since 1918 on account of the diversion of the general purposes fund, but interest on bank balances is still available for this laudable purpose. Mr. Clark would concentrate on the health instruction of elementary school-children, and on enlightening parents in regard to the preventable miseries of their own past school life. Generally speaking, he would promulgate health in the following forms: (1) lantern lectures at schools; (2) at cinemas, theatres, or halls; (3) unillustrated lectures at schools; (4) competitive essays by scholars in connexion with either of the above; (5) the health game or crusade in schools; (6) distribution of literature and competitive essays thereon. At a time when the efficiency of all branches of the insurance medical service is being closely scrutinised, it would not be amiss for the insurance committees, which were once actually known as national *health* committees, to see whether some onus does not rest upon them in publishing the elements of health in accordance with the information which is in their hands, and to some extent in their hands alone.

ACUTE SYPHILITIC TRANSVERSE MYELITIS.

Dr. H. N. Cole,[1] of the Department of Dermatology and Syphilology of the Medical Department of the Western Reserve University, and of the Cleveland City Hospital, who reports two illustrative cases, remarks that acute syphilitic transverse myelitis is actually not very uncommon. Of 1085 cases of syphilitic disease of the nervous system, mainly among Fournier's patients, Boulloche found 77 with a spinal onset. Williamson, in 1899, stated that between 1880 and 1899 118 cases of tabes occurred at the Manchester Royal Infirmary, as compared with 32 cases of spinal syphilis, six of which were examples of acute syphilitic myelitis and four of Erb's spastic type. There is a marked preponderance of males affected by the disease. Among 62 cases described by Kuh there were only six female patients. The process is most likely to occur in the active period of life, so that most of the patients were in the second or third decades of life, when acute syphilitic infection is most frequent. Cold, sexual excess, nervous disposition, alcoholism, trauma, and physical exhaustion have been regarded as of ætiological importance. The date of the syphilitic infection at which acute myelitis may appear varies considerably, ranging from two months after spirochætal invasion, as in one of Dr. Cole's patients, who still had a chancre of the lip and a papular syphilide, to 27 years after infection, as in one of Williamson's cases. The symptoms may develop suddenly within a few hours, or the process may require from several days to a week or more to develop fully. Pain in the back, of which both Dr. Cole's patients complained, and retention of urine are prodromal symptoms, as well as paræsthesiæ, girdle sensation, shooting pains, tiredness in the limbs, and muscle twitchings. Sooner or later complete paralysis of the limbs, in a few cases involving the arms, ensues. Sensation is generally affected. Bed-sores appear early and spread rapidly. There is usually an early infection of the paralysed bladder, the process travelling up to the kidney and resulting in a chronic pyelocystitis. Acute syphilitic transverse myelitis is therefore a severe process, and its termination is often fatal and rapid. Unless seen early the cord lesion causes great loss of irreplaceable tissue. One of Dr. Cole's patients died 37 days after the first pain in the back, and the necropsy showed syphilitic vascular changes and softening of the lumbo-sacral cord with accompanying pyelocystitis, while the other, in whom there were flaccid paralysis of the lower limbs, sphincter paralysis, and bed-sores, made rapid improvement under treatment with injections of arsphenamin and mercurial inunction, so that he regained complete control of his extremities.

HYDROGEN SULPHIDE.

USEFUL service has been rendered by C. W. Mitchell and S. J. Davenport in collating knowledge and observations with regard to the action of sulphuretted hydrogen.[1] This gas is formed when organic matter decomposes and it has been the cause of fatalities in sewers; it also occurs occasionally in mines, and is an ever-present danger in certain chemical processes. Nevertheless, as this review of the literature brings out, there is uncertainty as to the changes which occur in the body and result in poisoning. Many have worked at the subject, among others Dupuytren, Magendie, Claude Bernard, Hoppe-Seyler, Laborde, Gamgee, and Harnack. The gas, if concentrated, resembles carbon monoxide in the rapidity with which it may act; the subject appears to drop almost instantaneously. When less concentrated the symptoms of poisoning are proportionately slower in developing and the picture is nearer to that of poisoning by arseniuretted hydrogen. The smell of the gas which gives warning of its presence may explain why more cases do not occur; but a close observer, who once was suddenly overcome and dropped into an adjoining canal whence he was fortunately recovered to tell his story, declared to the writer that when in sufficient concentration to asphyxiate the gas is odourless and is only to be detected by a sweet taste. Possibly the acute cases belong to the anoxæmia series to which Haldane has paid special attention; certainly Haggard has recently suggested that inhaled hydrogen sulphide passes into solution in the blood, where it is rapidly oxidised, the oxygen being obtained from the hæmoglobin. At the same time the products of oxidation combine with the sodium in the plasma, whence may follow the later or more chronic effects of poisoning, such as mental and gastric disturbances and hepatogenic icterus. The review presented is held to establish that hydrogen sulphide is one of the most toxic of gases, comparable to hydrogen cyanide in the rapidity of its action and the concentration from which death will result. Even in concentrations of 0·005, such as may occur in industries, the gas is toxic. It is therefore an industrial poison with which we should be well acquainted.

SOPHISTICATED MILK.

AT the present time there is considerable activity within the ranks of the milk trade in regard to improving the methods of production and purveying of milk, particularly as to improvements leading to a diminution in bacterial contamination. The annual report for 1922 of Dr. G. Clark Trotter, medical officer of health for Islington (which has only just reached us), shows that the danger of chemical sophistication still has to be guarded against, and demands unsleeping supervision. His report gives some interesting particulars in regard to milk adulteration and what he describes as an apparently organised attempt on the part of itinerant vendors to foist upon the poorer population sophisticated milk. This took the form of different milk vendors, one

man being at the back of the whole concern and supplying the milk in bulk to each retailer, touring the poorer streets and underselling the legitimate vendors in price, the profit being made up by the use of adulterated milk. Considerable ingenuity was displayed, and one defendant admitted in court that as a general rule all customers who asked for "a pint" or "a quart" were served with the separated, or mixed milk, while those who distinctly specified "milk" were served with the genuine article. Within a period of about four months out of 18 official samples purchased from these vendors eight out of 14 were adulterated, the other four being sold as separated milk. In addition, 36 informal samples were purchased, of which 18 proved genuine and 18 adulterated. The fines with costs in the eight cases in which proceedings were instituted amounted to £35 13*s*., or an average of £4 9*s*. 1*d*. The amounts of fat abstracted ranged from 11 to 51 per cent. below the low legal standard. With these ridiculous fines the paying nature of the trade is very obvious.

Two other groups of vendors were dealt with on the same lines, both of which sold separated and new milk. Discussing one group, Dr. Trotter remarks that they distinguished with great nicety between the customers who asked for "milk" and those who did not specify, the former got the "new" and the latter "separated." In the interest of the children of these poorer districts this kind of fraud should be prevented, and protection given to those who are too ignorant to protect themselves. This could be given by prohibiting the sale of milk and separated milk from the same cart. The one practice should be no more possible than for one and the same itinerant vendor to sell from the one cart or barrow sound meat for human consumption and the class of meat designated as "cat's meat." Special action was also taken against adding colouring matter to milk, and 34 out of 46 samples of milk submitted to the public analyst were found coloured with annatto. Proceedings were taken in 26 cases and fines amounting to £121 8*s*. 6*d*. were obtained, an average of £4 13*s*. 5*d*. per case. It will be noted that the fines per case for this comparatively unimportant adulteration were higher than when fat was heavily abstracted.

Dr. Trotter remarks that at the Dairy Show in the Royal Agricultural Hall in October, 1922, leaflets were distributed and free samples given of both colouring matter and preservative, recommended to be added to milk without any warning that the sale of such milk would be illegal. He adds that no legal action could be taken, for although it is illegal to sell milk with colouring matter or preservative, it is not illegal to sell or recommend the colouring matter or preservative for addition to milk.

FUNCTIONAL TESTS IN RENAL TUBERCULOSIS.

IN the Lennander lecture on renal tuberculosis, published by Prof. G. Ekehorn in *Tubercle* for May, June, and July, 1923, it was stated that "functional tests in ordinary cases of renal tuberculosis are superfluous and therefore of no value." Diametrically opposite views are expressed by Prof. H. Wildbolz, of Bern, in a paper read before the Schweizerische Gesellschaft für Chirurgie.[1] Before he ventures on the diagnosis of renal tuberculosis, he insists on the presence of three signs—tubercle bacilli in the urine, pyuria, and functional deficiency of the kidneys. When this last sign is absent, and the rate of excretion of indigo is normal on both sides, tubercle bacilli and pus in the urine should not, in his opinion, be regarded as proof positive of renal tuberculosis, even if the tubercle bacilli are obtained from a ureter by catheterisation. He has come to the conclusion that functional deficiency of the kidneys is one of the earliest signs of renal tuberculosis, and he comments with surprise on the fact that a small tuberculous focus in a kidney, most of which is histologically healthy, should be able to impair its physiological activities. One of his many arguments in favour of the functional test before proceeding to nephrectomy is that the surgeon, who is unfortified by the findings of this test, may blunder seriously during the operation. For when he has exposed the kidney, it may strike him as looking so perfectly healthy that he has qualms about removing it. He may therefore leave it in place, or commit an even greater blunder—incise the kidney in search of tubercle. Even if he fails to find it, he may have started a fatal miliary tuberculosis by his act. If, on the other hand, the functional capacity of each kidney has been determined separately beforehand, and the kidney selected for nephrectomy has proved to be functionally defective as well as harbouring tubercle bacilli, the surgeon may proceed with equanimity to remove it in its entirety, be the evidence of inspection and palpation at the time of operation never so doubtful. In the course of about 500 nephrectomies for renal tuberculosis, Prof. Wildbolz has not once been misled by the evidence of the functional test, and he has to record only one case of uræmia following nephrectomy. This case occurred about 17 years ago, when his faith in the indigo test was not as confident as it has since become. The test showed delayed excretion of indigo on both sides. This warning was neglected, and the patient died a week after the operation. Post mortem, complete cavernous destruction of the remaining kidney was found. Prof. Wildbolz has little good to say of pyelography, pneumoradiography, and several other tests, the chief charm of which would seem to lie in their novelty.

EYESIGHT AND AEROPLANE-LANDING.

THE great majority of crashes to aeroplanes occur while landing the machines, and the importance not only of perfect visual acuity, but of good visual judgment in relation to this action has been proved by Comdr. E. C. Clements, R.A.F.M.S., who states[1] that the instructors in our Air Force are sufficiently impressed with the results as to apply at once for an opinion when a pupil shows signs of inability to land. The importance of frequent thorough examination of the eyes of airmen who crash is well brought out in the account of a case given by Major H. C. Neblett, of the Medical Corps, U.S. Army.[2] The patient had been for three years a pilot in the air service, and had no trouble in his eyes up to September, 1919, when he was making a flight at 8000 feet and fell into a series of "tail-spins" to within 1500 feet of the ground. He felt a severe pain in the right side of the head and the right eye, had photophobia and blurring of vision in both eyes, so severe that he could not attempt to land for about a quarter of an hour. The left eye soon became normal, but the right eye suffered for about ten days, and thereafter was very easily tired either by reading or flying. Pain returned six months later, and from time to time subsequently he became, from this cause, unfit for duty. In July, 1921, he crashed, without history of any definitely localised injury, but was for a time unfit to fly, his eyes giving trouble. There were an unusual number of crashes and poor landings in his history. Major Neblett observed him making poor practice landings on Nov. 20th, 1921, when he ultimately broke up his plane, though he was not himself hurt. His eyes were then carefully examined; the visual acuity of the right eye was found much diminished, with lessening of the supra-orbital and temporal field, and an almost complete detachment of the retina from below was found by the ophthalmoscope. Treatment for three months had no beneficial effect and he was retired "on account of practically total blindness in the affected eye." The history of this case shows the importance of carefully examining the eyes of all pilots who find a difficulty in landing.

CARCINOMA OF BARTHOLIN'S GLAND.

AT a recent meeting of the American Gynecological Society, Dr. Frederick H. Falls,[1] who reported an illustrative case, stated that primary carcinoma of Bartholin's gland was a very rare tumour of which not more than 20 examples had been recorded. The average age of the patients was 52·7 years, the youngest being 29 and the oldest 91. The tumours usually develop after the menopause, which has been regarded as a possible cause. Owing to its peculiar structure two types of carcinoma may develop in the gland—viz.: (1) A squamous-celled tumour from ducts near the surface in uninflamed glands or in deeper parts of the ducts in glands which have been the seat of chronic inflammation leading to alterations in their lining membranes; and (2) columnar-celled carcinoma or adeno-carcinoma arising from the gland acini or from the unaltered duct epithelium in their deeper portions. Metastases frequently occur in the inguinal glands on the same or opposite side. Recurrence is extremely common, as in all carcinomata of the vulva. Sinus formation is common and may be present for years before evidence of malignancy is seen. No instance of bilateral carcinoma of Bartholin's gland has been reported, but in Sitzenfrey's case there was a chronic inflammation of the gland on one side associated with carcinoma of the opposite gland. The symptoms are swelling of the labium in the region of the gland with œdema of the remnants of the hymen. The swelling in many cases is painless at first, but in a few months tenderness and an aching sensation develop. Sometimes there is severe lancinating pain radiating to the coccyx and groin, which is aggravated by walking and coitus, and is usually worse during menstruation. On local examination a hard lump, ranging in size from a hickory nut to an orange, is found. It is freely movable in the early stage, but later becomes fixed to the surrounding structures. The skin over the tumour may be thin and bluish and tends to ulcerate. The course is usually rapidly fatal, but cases have been recorded in which there was no recurrence after three years (Eden) or even six years (Trotta). The diagnosis as a rule is easy. The chief diagnostic points are the age, which is usually over 50, the hardness of the tumour, and its tendency to fixation. Pain, especially if associated with œdema of the vulva and skin over the gland, is very suggestive. Metastases to the regional lymphatic glands, which become hard and shotty, and a tendency of the tumour to break down are important signs. In doubtful cases the diagnosis can be established by biopsy. Treatment consists in removal of the tumour as soon as the diagnosis is made, and the subsequent application of radium and X rays to the affected areas and also to the opposite site and inguinal regions. In Dr. Falls's case, which occurred in a woman aged 38, the tumour was found to be adherent to the levator ani in its lower pole and to extend to the ramus of the pubis laterally. The carcinoma was medullary in type and probably arose from duct epithelium. Removal of the growth was followed by application of radium to the wound and corresponding inguinal region, and later by X ray treatment. At the time of publication 14 months had elapsed since the operation without any evidence of recurrence of the growth.

[1] American Journal of Obstetrics and Gynecology, December, 1923.

ENTERIC FEVERS AND SCAVENGING.

Prof. Harold Kerr, medical officer of health for Newcastle-upon-Tyne, in a paper read before the Epidemiological Section of the Royal Society of Medicine on Jan. 25th, considered the factors influencing the prevalence of enteric fever and diarrhœa. Some 30 years ago a sanitary congress was opened with the remark: "The north countryman dearly loves a privy-midden." It was a surprise to many of Dr. Kerr's audience to learn how many of these evidences of misplaced affection still remain in important great towns of the north. Apparently neither a regard for the amenities of life nor for sanitary improvement has been able to counterbalance the cost, whether to ratepayer or property owner, of abolishing these urban inconveniences. Dr. Kerr set out from the standpoint that formerly the incidence of enteric fever and diarrhœa in a district was a fair indication of the efficiency of its methods for the disposal of excreta and refuse. In the last decade of the nineteenth century many reports by medical officers of the Local Government Board and medical officers of health supported this view. It was shown that privy-midden towns grouped suffered more than water-closet towns grouped from diarrhœa and enteric fever and that the incidence of these diseases was greater on houses supplied by conservancy closets. Dr. Kerr's investigations seem to show that with a lessened prevalence of these diseases it is not so easy to make clear deductions now. The decline of enteric fever has always been somewhat of a mystery and has undeniably preceded in many towns the conversion of the middens. In some cases of badly infected towns the immunising of the more susceptible members of the population, whilst sanitary measures have been put in hand, must have had an appreciable effect. For example, in Sunderland, with a population of under 150,000, more than 5000 cases of enteric fever were notified in the 15 years succeeding the introduction of the notification of infectious diseases. In 1911 Dr. Kerr obtained figures from 41 great towns which he examined for correlation between conservancy methods and prevalence of bowel infections, but he came to the conclusion that other circumstances, such as constitution of population, occupations, habits, wealth, climate, situation and natural amenities, water-supply, drainage, and hospital accommodation, differed so much that it was only fair to compare each town with itself. He found, however, that the conversion to the water-carriage system was invariably accompanied by a decline in enteric fever, though the rate of decline has varied greatly in different towns. The Local Government Board (1910) Report on Enteric Fever in the County of Durham emphasised the primary importance of conservancy methods in maintaining high enteric and diarrhœa rates, but Dr. T. E. Hill, the county medical officer, has since pointed out that efficiency of scavenging is probably quite as important. The inconsistency of the results prompted Dr. Kerr to continue his inquiry in 1921 and to extend it to other factors such as scavenging and the distribution of dried milk. All districts showed a great improvement in the period 1918–22 over 1906–10, and this is specially noticeable when the hot year 1921 is compared with the hot years 1906 and 1908. But there are inconsistencies in the table. Among towns with a high proportion of conservancy closets Hull, Middlesbrough, Wigan, Warrington, and Darlington had high rates for enteric and diarrhœa in both periods; while in Bolton, Derby, Huddersfield, Halifax, and Rochdale the enteric rate is high and diarrhœa low; and in Gateshead, South Shields, St. Helens, and Wolverhampton the enteric rate is low and diarrhœa high. Newcastle, with 8½ per cent. of privies, has slightly more enteric and slightly less diarrhœa than Gateshead with 76 per cent. of privies. Reports on scavenging show high standards on paper which Dr. Kerr thinks are too good to be true. Privy conversion, he concludes, played a notable, if not a chief part in the past, in reduction of enteric and diarrhœa incidence. It is not nearly so clear that conversion to-day is essential to a low enteric rate provided that scavenging is efficient. Modern road-making and methods of cleansing and replacement of horses by motors in general service have all played their part in diminishing disease. The substitution of dried for fresh milk would cut out another link in the chain of communication between midden and man. Popular education, however, and growing civilisation remain the chief means of combating diseases of uncleanness.

B.M.A. ANNUAL MEETING, 1924.

THE ninety-second annual meeting of the British Medical Association will be held in the latter part of July at Bradford, when Mr. J. Basil Hall, consulting surgeon to the Bradford Royal Infirmary, will succeed Mr. C. P. Childe in the presidential chair. The annual representative meeting begins on Friday, July 18 h, at 10 A.M., to be continued on the three following week days. Dr. R. Wallace Henry will again preside over this body. The scientific sections will meet from 10 A.M. to 1 P.M. on Wednesday, Thursday, and Friday, July 23rd to 25th, the afternoons of the same days to be given up as heretofore to laboratory and clinical demonstrations. The usual exhibition of surgical appliances, foods, drugs, and books will be opened on July 22nd, at 9.30 A.M. The annual dinner of the Association is fixed for the evening of Thursday, July 24th. A popular lecture entitled "The Sun Cure" will be delivered by Sir Henry Gauvain on Friday, July 25th. The honorary local general secretary of the meeting, on whom even now the burden must begin to fall, is Dr. W. N. West Watson, Victor Lodge, Manningham, Bradford.

POVERTY IN GERMANY.

OUR Berlin correspondent has referred on more than one occasion to the distressful effects of poverty on the health of the coming generation in Germany, describing unhappy conditions which, in the opinion of many on both sides of the Rhine, constitute a claim on the charity of the world. The British Appeal for Relief in Germany, a body which has made this matter its especial care, nevertheless feels that sufficient information on the actual condition of the children has not yet been obtained, either for a wise administration of large funds or to enable the Committee to press the appeal in an adequate campaign. To endeavour to form some estimate of the true state of affairs, this Committee has arranged for two doctors to go to Germany and to investigate the conditions at first hand on behalf of three organisations—namely, the Save the Children Fund, the Universities' Committee, and the Society of Friends' Council for International Service. In this capacity Dr. Helen Mackay, whose studies on rickets in Vienna have been published in these columns, and Dr. Melville Mackenzie, lately medical officer to the Friends' Russian Famine Relief Unit, for the Friends' Council in Russia, have been asked to make a strict report on the state of nutrition of the children in various districts in Germany, with special reference to those under school age and of the students.

THE IMMUNITY OF CHILDREN TO GASTRIC AND DUODENAL ULCER.

IN connexion with a case of perforated ulcer of the stomach in a girl, aged 7, Dr. Lennart Norrlin[1] draws attention to the remarkable immunity to gastric and duodenal ulcer enjoyed by children over the age of one year. As he points out, every case of perforation of the stomach or duodenum in the large Swedish towns comes to operation or necropsy, and it is thus almost impossible to overlook the accident. In two papers dealing with large statistics and published in Swedish this complication has been shown to be practically unknown in childhood, and of 518 cases of perforation collected by Dr. Norrlin from the Swedish and Finnish literature, there was only one case in which the patient was under the age of 15. This patient was a boy aged 14. But while children above the age of one year practically never suffer from ulcers of the stomach and duodenum, this disease is not rare in the newborn. Thus, Collin has found ulceration of the duodenum in 17 infants among 237 necropsies, and Bonnaire, Durante, and Ecalle have found two such cases among a total of 4000 necropsies. Among 1109 necropsies on infants under the age of one year, Schmidt found 20 cases of duodenal ulcer, the ulcers in several cases being multiple. In seven of these cases death was due to a hæmorrhage from the neighbourhood of the ulcer, and in three cases to peritonitis. In the remaining cases the cause of death was some intercurrent disease. Dr. Norrlin asks: Why should the age from the second year to puberty be so free from gastric and duodenal ulceration, whereas the newborn and adults are so prone to suffer from it? Children are notoriously reckless over what they eat, but they do not have to pay for their recklessness with gastric and duodenal ulcers. If the cause of this immunity could be discovered, light would probably be thrown on the lack of immunity shown by the newborn and adults, and Dr. Norrlin suggests that the determining factor may prove to be the behaviour of the glands of internal secretion.

[1] Acta Chir. Scand., Dec. 22nd, 1923.

Dr. Alfred Mantle, who is president of the Harrogate Medical Society, has just been awarded the prize by open competition in this and other countries for the best essay on the cause and prevention of rheumatic fever, and has decided to devote the awarded £120 to propaganda work for educating the poorer classes as to the prevention of rheumatism in childhood. A considerable percentage of heart troubles are known to be of rheumatic origin in early life, and may be prevented if proper care be taken by an early examination of the throat and mouth, and by the treatment of certain conditions which we know may lead to rheumatism and possibly infection of the heart. The poor are always ready to consider any pains about the limbs in children as "growing pains," and the importance of rest in bed at this time cannot be overestimated, but is neglected, and much can be done to remedy this by medical officers and the children's welfare societies' health inspectors educating the mothers as they have done so successfully in the tuberculosis campaign.

THE latest list of honours contains only one medical name, that of Dr. Henry Jackson, the well-known Mayor of Wandsworth, which is one of the largest of the metropolitan boroughs. Dr. Jackson, who graduated in medicine at Cambridge and at Edinburgh, taking also the degree in science at the University of London, began his scientific career as a worker in advanced chemistry, having carried out researches, singly or in coöperation, on the aldehydes, the derivatives from citric acid, and on glycogen; he is the author of many papers which have appeared in, among other places, the Proceedings of the Royal Society, and the Transactions of the British Association, the Chemical Society, and the Cambridge Philosophical Society. While at Cambridge he was a Fellow and Lecturer of Downing College, but leaving the University for London he soon became a great influence in municipal politics in the district where he went to reside. His work for the borough of Wandsworth has been strenuous and directed throughout towards the public good, so that all political parties in his constituency will approve heartily of the knighthood which has been bestowed upon him. We add our congratulations to theirs.

RENEWAL OF EXCHEQUER GRANTS.—The Ministry of Health announces the decision of the Government to remove the present restrictions on the grants for the development of the public health services—maternity and child welfare, tuberculosis, venereal diseases, welfare of the blind and port sanitation—which are directly aided by grants from the Exchequer. A circular has been issued to local authorities informing them that the Minister will be prepared, with the approval of Parliament, to make grants on the prescribed basis for such further development of these schemes as is considered advisable by the authorities and is within their existing powers, subject to the ordinary process of approval of particular proposals by the Ministry.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LVIII.—THE SURGICAL TREATMENT OF HÆMATEMESIS.

THE causes of hæmatemesis are numerous and with only a few does the question of surgical interference arise. Often the chief problem is to determine the cause, and care must be taken to ascertain that the blood does come from the stomach and is not swallowed and then vomited. In a large group of cases the hæmorrhage arising from the stomach wall is a symptom of some general condition and is rarely in itself a cause of danger or death. These conditions may be grouped as follows: (*a*) Acute specific fevers—e.g., small-pox, typhoid, yellow fever, and malaria; (*b*) toxic conditions—e.g., phosphorus poisoning, acute yellow atrophy of liver; (*c*) constitutional disease—e.g., hæmophilia, profound anæmia; (*d*) back-pressure upon the stomach—e.g., heart disease, cirrhosis of liver. In all these conditions the treatment will be directed mainly against the underlying disorder, or, if the hæmorrhage be severe, will be symptomatic and carried out on medical lines. Though in certain cases of anæmia a splenectomy, or in cirrhosis some operation to aid the obstructed circulation, may have to be undertaken, such steps should never be carried out during or shortly after a severe loss of blood, but should be delayed until the patient's condition has improved.

Acute Gastric Ulceration.

Recent investigations tend to show that in all cases where the loss of blood is due to an acute erosion of the gastric mucosa there are minute ulcers which lead to an aneurysmal dilatation of the small vessels with subsequent perforation and hæmorrhage, and probably in none of these cases is there a diffuse oozing of blood from the mucous membrane (gastrostaxis). The acute erosions may be seen clinically in three different forms: (*a*) As a complication of some acute septic condition; (*b*) as a cause of severe hæmorrhage with few, if any, other symptoms; (*c*) as a cause of the gastric ulcer syndrome in young women.

In Group (*a*) the hæmatemesis may occur as a complication of some septic wound or focus or may arise in a patient who is clearly suffering from a profound septicæmia. In this group the hæmatemesis must be regarded as a serious complication indicative of a widespread septicæmia. The hæmorrhage is often extremely severe, and even if not fatal in itself will add greatly to the danger of the debilitated patient. It is evident that no operation upon the stomach is likely to be curative, but every attempt must be made to combat the infection in the primary focus and to overcome the toxæmia. Oral administration of suprarenal extract, ℥ ii. in an equal quantity of water two-hourly (six doses), is one of the best methods of controlling the hæmorrhage. The patient's anxiety must be allayed by morphia, and after the bleeding has ceased, or, indeed, sometimes before, it may be wise to give a blood transfusion. In my experience horse serum has proved of little or no avail. Operation should only be undertaken at the express wish of the physician; the result will probably be very unsatisfactory, for although the hæmorrhage may be controlled it will be rarely indeed that the septic infection can be combated.

Groups (*b*) and (*c*) differ from Group (*a*) in so far as there is little or no clinical evidence of sepsis. In Group (*b*) the patient—frequently a young woman—will have one or more severe attacks of hæmatemesis unassociated with any other evidence of sepsis or of gastric ulceration. She may have been in perfect health until there is a hæmatemesis sufficiently severe to cause a profound secondary anæmia. The hæmorrhage may be repeated or the single loss of blood may be sufficient to endanger life. In Group (*c*) the symptoms are rather different in so far that the patient—also most frequently a young woman—will have presented for weeks or months pain, vomiting, and loss of appetite, symptoms characteristic of an acute gastritis with ulceration. Here again the hæmatemesis is likely to be severe, and if repeated may be fatal. In this group there has been much discussion as to the advisability of surgical treatment. The type of patient, the absence of periodicity of the symptoms, the relatively short history, the character of the pain, vomiting and loss of appetite should make certain the differential diagnosis of acute from chronic gastric ulcer, and since acute ulcers are often multiple and are associated with an acute gastritis, it is evident that the treatment of choice will be medical. The patient should be kept absolutely at rest and given no food by mouth, her anxiety should be controlled by morphia, and the bleeding diminished by the administration of ice, and if necessary by suprarenal extract. In a few cases, however, the hæmorrhage is so severe or so frequent that operative treatment has to be considered. Only where the patient is in a condition of the gravest danger and where an experienced physician is of the opinion that death will ensue if the hæmorrhage be not immediately controlled should operation be undertaken. Since there is a diffuse gastritis with multiple areas of ulceration no attempt to control a local bleeding point is likely to succeed, and since these patients are often in a condition of severe collapse, no time must be lost in making a useless search for a bleeding point. I believe that the only step which is likely to control the hæmatemesis is a posterior gastro-enterostomy, preferably combined with temporary occlusion of the pylorus, but certain surgeons are sceptical on this point and it is not easy to offer satisfactory proof. If a surgeon is convinced by his own figures that the results of such treatment are unsatisfactory he will be justified in refusing surgical interference. My own view is that a certain group of patients will be saved by such a measure, especially if it be combined with blood transfusion immediately previous to the operation. Among 17 cases, all desperately ill and going downhill, on whom I have performed this operation 11 were cured thereby.

Chronic Gastric and Duodenal Ulcer.

Severe hæmorrhage with a chronic gastric ulcer is not nearly so common an event, and presents less difficulties. If it does occur there may be a large loss of blood which spontaneously ceases, and is unlikely to recur or to be fatal, except if a very large artery is perforated, when the patient dies before treatment can be begun. Acute hæmatemesis in a patient with a definite past history of chronic ulcer is a clear confirmation of its presence and an indication for surgical treatment which, however, should not be carried out until the patient has recovered from the effects of the hæmatemesis. He should be kept at absolute rest in bed, on a modified diet or no food at all by mouth, and on medical treatment to control the hæmorrhage. When his general condition has improved operation should be strongly urged, for the probability of another hæmorrhage or a perforation must be remembered. Rarely the hæmorrhage will be so severe that an operation may hold out the only hope of controlling the bleeding vessel. With a large indurated and penetrating ulcer it is unlikely that the ligature of any vessels will control the bleeding, and safety can probably only be obtained by such radical steps as local excision or partial gastrectomy, procedures which, in a patient profoundly ill, are likely to have a high mortality. These dangers can to a large extent be overcome by a previous blood transfusion, which should be done very shortly before the operation so that there is no further loss of blood between the two steps. In this way there is a good chance not only of saving the patient's life, but of permanently curing the gastric lesion.

Duodenal Ulcer.

Severe hæmorrhage from a duodenal ulcer gives rise to a very similar problem, but here hæmorrhage is a

more dangerous symptom and is more commonly fatal, so that a larger number of cases will demand surgical interference. To-day this is, however, more commonly realised, and hence fewer cases of duodenal ulcer are allowed to progress to hæmorrhage before an operation is advocated. It cannot be too strongly urged (1) that operation should be undertaken as soon as the ulcer is diagnosed and before the onset of the hæmorrhage, and (2) that should the case have been neglected and a hæmorrhage have occurred, operation should be advocated *without* a preliminary course of medical treatment. It is in this that the chief distinction lies between the gastric and duodenal ulcers. The hæmorrhage of a gastric ulcer is likely to cease, and the patient's condition to improve if he be given strict medical attention. In the case of a duodenal ulcer such a happy outcome is not to be expected. The operative steps will also be different, except for the preliminary blood transfusion in any debilitated patients. If the anterior wall of the duodenum be embedded with a running purse-string suture the hæmorrhage can always be controlled, for even if the ulcer be situated posteriorly, so much of the anterior wall can be turned in that the duodenum is entirely obliterated and the bleeding point compressed. A posterior gastro-enterostomy is then rapidly performed so that a permanent cure of the ulcer is probable.

Gastric Neoplasms.

Whether gastric neoplasms are innocent or malignent, they do not, as a rule, call for treatment owing to the severity of the hæmorrhage. When a large vessel is eroded a fatal termination rapidly ensues, but in most cases the hæmorrhage is only one of several symptoms indicating the nature of the lesion ; even if it is severe, treatment will be directed towards radical removal of the tumour rather than control of the bleeding, for if the tumour is inoperable this is almost impossible to achieve with certainty. If, therefore, secondary deposits are present and radical treatment is clearly impossible, reliance should be placed on medical measures alone.

Trauma.

External accidental trauma may occasionally give rise to a small tear of the mucosa, associated with relatively slight and transient hæmatemesis. The presence of such a symptom is, however, always suggestive of a more severe injury. A very careful watch must be kept, and if hæmorrhage be severe or there be the slightest evidence of a perforation—and this usually means early tenderness and rigidity—laparotomy should be immediately performed. In either case the torn portion will be carefully sutured, and the bleeding vessels thus controlled.

Surgical Trauma.

Most operations of gastro-enterostomy or partial gastrectomy are followed by a little loss of blood, but when this is considerable it is often difficult to decide whether the hæmorrhage is due to a rather excessive oozing or whether a larger vessel has not been properly controlled. The milder degrees of such hæmatemesis can nearly always be stopped by cutting off all fluids by the mouth, and giving morphia and suprarenal extract as directed above. Should this not control the hæmorrhage, or should the pulse continue to rise, a second operation, though a severe strain upon the patient, will be essential. I have not yet met with a case where this was required. Hæmorrhage occurring some months or years after a gastric operation is strongly suggestive of the presence of a recurrent or of a gastro-jejunal ulcer, and is an indication for further operative treatment. It is rarely severe or dangerous, but should it be so, the surgical treatment is that of hæmorrhage from a chronic gastric or duodenal ulcer.

Splenic Anæmia.

Splenic anæmia may lead to very severe losses of blood from the gastric mucosa, the local lesion taking the form of acute erosions. Since a considerable degree of anæmia precedes the hæmatemesis, the patient will often suffer much collapse. Wherever possible, therefore, an effort should be made to tide the patient over this before a splenectomy is performed. If the hæmorrhage persists, in spite of medical treatment, transfusion should be performed and the spleen then removed. Even after a successful splenectomy attention should be directed to the anæmia and the general condition, for although the majority of cases are cured by this surgical measure, examples of hæmatemesis occurring several years after the operation have been reported. In such cases the loss of blood is usually from a ruptured œsophageal vein.

A. J. Walton, M.S. Lond., F.R.C.S. Eng.,
Surgeon to the London Hospital.

Special Articles.

A REPORT ON THE GEOGRAPHICAL DISTRIBUTION OF CANCER MORTALITY.

A preliminary report by Sir George Buchanan and Dr. Major Greenwood on the International Differences in Mortality from Cancer has appeared in recent numbers of the *Bulletin* of the Office International d'Hygiène Publique, and is the result of the questionnaire sent out in January, 1923.

The Questionnaire.

In view of the vast proportions of the subject and in order to ensure that the returns from the various countries should be comparable, the questionnaire was limited in the first instance to the following points :—

(*a*) The degree to which reliance can be placed on the accuracy of the cancer mortality statistics, having regard (1) to the regulations governing the issue of death certificates, and (2) to the proportion of deaths in which either no medical certificate as to the cause has been furnished, or in which the cause is too obscure or too vaguely described for statistical purposes.

(*b*) Whether statistics are available as to the distribution of cancer mortality according to geographical conditions and according to occupation.

(*c*) Whether information is available as to the proportion of deaths from cancer supervening in hospitals or other public institutions.

(*d*) Whether there are statistics as to post-mortem confirmation of the presence of cancer.

(*e*) How far the classification of deaths from cancer according to the particular organ of the body involved furnishes a reliable indication of the relative incidence of the various forms of fatal cancer.

(*f*) The number of years over which cancer mortality statistics can fairly be compared.

(*g*) Bibliography of cancer statistics available in each country.

(*h*) Any other relevant observations.

General Conclusions.

This preliminary inquiry will, it is obvious, clear the ground for a more detailed comparative study to be undertaken subsequently. Some of the general conclusions drawn from the reports from the different countries are as follows :—

1. There is an almost unanimous belief that mortality from cancer is on the increase, Norway alone not subscribing to this belief.

2. There is a unanimous opinion that all cancer mortality statistics are more or less affected by various sources of error arising mainly from difficulty in obtaining a medical certificate as to cause of death, difficulties in arriving at a diagnosis, and unwillingness on the part of the doctor or of the relations of the patient to admit the existence of cancer.

3. There appears to be no country, save, perhaps, Switzerland, in which any reliable statistics are available as to the proportion of deaths from cancer verified by post-mortem examination.

4. No very satisfactory statistics are available as to the proportion of deaths from cancer occurring in

hospitals or other public institutions. The most complete returns are those afforded by Switzerland, England and Wales, and Sweden.

5. From these and other causes it is difficult exactly to gauge the importance of local differences in the cancer mortality statistics, but these differences appear, at least in part, to be real differences—i.e., they are greater than can be accounted for by variations in procedure in the different countries in matters like diagnosis, registration, and certification.

6. There are striking differences in the different countries in the incidence of cancer of the breast and of the female genital organs. This is strikingly shown in the case of England, Holland, and Italy. For a considerable series of years the mortality in Italy and Holland from these two causes has been somewhere about half the corresponding mortality in England and Wales.[1]

A short abstract follows of the reports from some of the countries which replied to the questionnaire.

Denmark.

Owing to the stringency of the Danish laws relating to death certificates very few deaths occur in which the cause has not been verified by a qualified medical man, while the number of deaths from malignant disease which are included under the heading of "Deaths attributable to unknown or ill-defined causes" must almost certainly be negligible. In Denmark, therefore, the cancer mortality statistics may be looked upon as being as reliable as the present state of medical knowledge on the subject will permit.

Statistics are available for deaths from cancer in each town and rural district. An inquiry into the mortality-rate in various occupations is being conducted, and the results will be published in about a year. Certificates as to the cause of death may be looked upon as equally reliable all over the country, since practically all the doctors have received similar training, and equal facilities are available for medical attendance in every district.—Since 1921 statistics have been published giving the detailed causes of death occurring in most of the hospitals and clinics of the country.—There are no records of verification by post-mortem examination of deaths from cancer.—In most cases the localisation of the malignant disease is stated on the certificate, and save in Copenhagen all certificates not so completed are returned for the information to be added. It is, of course, not always possible to be sure which is the primary site of the disease.—No official statistics are available prior to 1876. Some of the apparent increase in cancer mortality must, no doubt, be attributed to the improvement in diagnosis which is constantly being effected. —Attention is also drawn to the probability that the apparent increase in mortality from cancer is also due to the diminution in the mortality-rate from other diseases, especially from acute epidemic diseases. A table is given correlating the falling tuberculosis death-rate with the rising cancer-rate for each decennium from 1890.

Great Britain.

Statistics from this country are probably reliable as far as the points specified under question (*a*) are concerned, although "senility" may conceal a few deaths from cancer. A greater source of error, however, lies in mistaken diagnoses, and in a certain reluctance on the part of the doctor to certify cancer as a cause of death.

The annual reports and decennial supplements issued by the Registrar-General give the statistics of deaths from cancer grouped according to sex, age, and occupation. While it is probable that not all the statistics are equally reliable, they are considered to be sufficiently accurate for purposes of comparison.—Since 1910 a register has been kept of deaths occurring (*a*) from all causes, and (*b*) from cancer, in Poor-law hospitals and other public institutions.—The information as to post-mortem verification of deaths from cancer is still incompletely furnished on death certificates, the furnishing of this information not being compulsory.—The statistics as to the relative incidence of cancer in the various parts of the body are probably comparatively complete for those cases in which the disease is accessible, the only source of error being the occasional difficulty in ascertaining which was the primary focus of disease.—The statistics for deaths from cancer are probably fairly comparable since 1897.

Italy.

The statistics of deaths from cancer are, on the whole, reliable, although probably vitiated by intrinsic sources of error.

Deaths from malignant disease show an appreciable and progressive increase for the last 30 years (during which period the annual statistics may fairly be compared), contrasting with the sharp decline in the general mortality-rate. —The mortality is greatest among females, especially over the age of 40.—The increase is found chiefly in malignant disease of the gastro-intestinal tract.—Post-mortem verification of the cause of death is only exceptionally undertaken, and bears no relation to the incidence of deaths from cancer.

The Direction Générale de la Santé Publique is investigating the question as to how far such factors as heredity, environment, occupation, and diet are concerned in the increased cancer incidence.

Norway.

The mortality statistics are accurate and reliable for the last 20 years, and in 1918—the latest year for which the figures are given—92 per cent. of all deaths were medically certified. The excellent statistics are ascribed to the facts that the people generally are well instructed on such matters, and that the population is so small as to make details of their social life easy to ascertain.

The regional distribution of cancer in Norway has been studied on several occasions, but not the occupational distribution. This matters the less that most of the people (70 per cent.) live either in the country or by the seaside, as agricultural workers and fishermen respectively, the regional divisions thus representing more or less accurately the professional divisions.—No statistics of deaths from cancer in hospitals or other institutions are available in Norway.—Post-mortem verification is rare.—Up to 1920 specification of the particular region of the body affected was only required in the case of cancer of the skin, digestive organs, breast, and uterus, but since that date the specification has been extended to include, in the case of carcinoma, 26 different localisations, and in the case of sarcoma, three. It is hoped that this information will later show any correlation that may exist between particular types of the disease and particular districts.—There does not appear to have been any appreciable increase in the number of deaths from cancer during the 25-year period over which the figures are comparable.

Holland.

The statistics, on the whole, are reliable as an index of the cancer mortality, but are probably under rather than over the mark, since over 8 per cent. of deaths are registered as due to senility, and nearly 6 per cent. to "unknown causes."

A few statistics are available as to cancer deaths grouped according to geographical regions, but they are too scanty to have more than a local value. A report was made for the years 1908–1911, showing the cancer death-rate among males grouped according to occupation, the occupations showing the highest rates being barbers, hair-dressers, distillers, and telegraphists.—Very scanty statistics are available as to deaths occurring in hospitals or other public institutions.—Very few cancer deaths are verified by post-mortem examination. Those that are so verified occur in hospitals and are precisely the cases in which there has been no doubt as to the diagnosis.—No details are given on the certificates as to the particular organ involved. Old statistics which are available show that the stomach is by far the commonest site of malignant disease, the liver and bile-ducts coming second. The study is now being brought up to date, and the results will be published later.—The statistics are comparable since 1901.—The cancer mortality in the Low Countries has appreciably increased during the last 20 years.

Sweden.

The statistics as to cancer mortality are not so complete or reliable as regards the returns from the rural districts.

There are no statistics relating to the comparative incidence of cancer according either to geographical distribution or to occupation. The incidence, however, appears to be greater in Central Sweden than in the outlying parts—a fact which cannot be accounted for by any difference in the average age of the respective inhabitants, or by a greater proportion

[1] This difference has been chosen by the Office International d'Hygiène Publique and by the League of Nations for an intensive study, which is now proceeding under the direction of a Cancer Subcommittee of the League's Health Committee.

of town dwellers in the former. The difference is tentatively ascribed to the operation of various social factors.—Statistics as to the proportion of deaths from cancer supervening in hospitals and other public institutions are available, and show that an average of 11 per cent. of all deaths occurring in these institutions are due to malignant disease.—There is no post-mortem verification of death.—The classification according to the site of the disease is apparently made in regard to public institutions only. Taking the figures for the year 1920, it was found that the commonest sites of cancer in men are: (*a*) stomach, (*b*) intestines, (*c*) lips, (*d*) skin; and in women, (*a*) stomach, (*b*) breast, (*c*) genitalia, and (*d*) intestines. Cancer of the lips is four times more frequent in the rural than in the urban districts, and is more frequent in small than in large towns. Cancer of the breast and female genital organs is more frequent in Stockholm and in the island of Gottland than in other parts of the country.—There is no definite period over which the returns are strictly comparable, but since 1880 there has been a gradual improvement in diagnosis and in the general level of culture and standard of living; an increase in the number of hospitals and a general prolongation of life; all of which factors tend to produce an apparent increase in the incidence of cancer.

Switzerland.

In spite of a few inherent and inevitable sources of error the Swiss statistics as to causes of death are looked upon as approximately correct. In only a small percentage of cases is the cause of death not specified, the same being true of mistakes in diagnosis. The exact margin of error cannot be ascertained but is almost certainly small.

No statistics are available as to the cancer mortality occurring (*a*) in the various geographical regions, or (*b*) in specific occupations, or (*c*) in public institutions, but such information could in each case easily be furnished.—Whenever an autopsy is held, this fact is entered upon the certificate, so that it would be an easy matter to obtain statistics upon the point.—It would be perfectly feasible to compile from the Swiss statistics tables showing the particular organs of the body affected, not only for the country as a whole, but also in certain specified regions. A study of the correlation between the incidence of special types of cancer in the different parts of the country might give valuable information as to the part played by race, diet, and other factors.—The statistics are fairly comparable since the year 1901.

United States of America.

A reliable indication of the cancer mortality is afforded by the system of registration.

A comparison of cancer mortality statistics from a geographical point of view would be possible, but would be misleading owing to the fact that patients are often transferred to other places in which there may be a better hospital service. The data available as to occupation are at present so scanty as to make statistics on this point also highly misleading.—No statistics are available for the country as a whole to show what proportion of deaths take place in public institutions.—In 21 States the death certificate specifies whether the cause of death has been recognised clinically, at operation, or by post-mortem examination.—As far as the Registration Area is concerned, there are sufficient data for ascertaining the relative proportion of deaths from cancer affecting the different organs of the body.—Statistics for the district of Columbia and for the ten States originally included in the Registration Area are comparable since the year 1900.

Union of South Africa.

Medical certification of causes of death is only obligatory in urban districts, and only as far as Europeans are concerned. Statistics as to the mortality from cancer cannot, therefore, be looked upon as reliable.

For the last four years the geographical grouping of mortality statistics has been adopted. No statistics are available as to the relative cancer incidence in the different industries.—There are at present no data relating to deaths occurring in public institutions.—No post-mortem confirmation of diagnosis is available.—The international classification of causes of death has been in use since 1913, as far as Europeans are concerned.—The statistics for the Union as a whole and for each province are comparable since 1913.—It has been found that among the Europeans of South Africa the cancer incidence approximates very nearly to that in the countries of Europe, while among the indigenous peoples living under primitive and natural conditions cancer is extremely rare.

CHANGING FACTORY CONDITIONS: RISING STANDARDS AND FUTURE DEVELOPMENT.

II.—THE RISING STANDARD OF SAFETY.[1]

IT might be argued that there ought to be appended to the title of this section a question mark, for the statistics are incomplete and unsatisfactory. It is not possible to get even approximately accurate figures as to the number of persons covered by the Factory Acts in different years, but, such as the figures are, they give no clear impression of a diminishing list of casualties, as the corresponding figures for industrial disease most unmistakably do. The standard of notification changes, and the numbers of non-fatal accidents must be taken with some caution, but the number of fatal accidents reported has probably been pretty correct for a good many years past; in statistics, as elsewhere, "stone dead hath no fellow." It is rather discouraging to find that there were 1385 fatal accidents in 1919 and 1404 in 1920, as against 946 fatal accidents in 1909 and 1080 in 1910; these years may be compared fairly because they were all of them years of good trade, though some allowance is to be made for the transition from war conditions to peace conditions in 1919. The figures for the war years being not of much service for comparison are excluded from consideration and the averages are taken for groups of four years, when we get the following results:—

	Average.			
	1902–05.	1906–09.	1910–13.	1919–22
Fatal accidents	1,060	1,071	1,208	1,146
All accidents	94,133	118,971	153,222	113,490

When we take into account extensions of the scope of the Factory Acts—in 1907 laundries were brought in, and also philanthropic institutions—the rising standard of notification helped by the Workmen's Compensation Act of 1906, and the great differences in numbers employed due to trade booms or trade depressions, the broad effect produced by these figures is of some but of no striking improvement. At all events the figures are sufficiently lurid, especially when we remember that they do not include those of the three most dangerous occupations—coal-mining, seafaring, and work on the railways.

In 1910 there was a Departmental Committee on Accidents which recommended among other things more specialisation on the part of the factory inspectorate and frequent conferences with the employers and workpeople concerned. A good deal has been done in both directions. There has been intensive study by particular inspectors of particular industries, and at least one inspector, Mr. L. C. McNair, has shown a remarkable gift for suggesting, and in some cases designing, safeguards. But a limit is set to specialisation by the fact that the whole staff of the inspectorate only numbers 200, that there is much routine work, and much demand for vigilance. Along the line of conference with employers and workpeople, a good deal has been accomplished. The regulations for the very dangerous woodworking trade were the outcome of conference with subcommittees of various joint industrial councils concerned and also with the makers of machinery. Consultation with makers of machinery has proved to be one of the most fruitful lines of action. It is obviously better that guards should be designed simultaneously with the machines, and should be, if possible, an integral part of them, but this has not been so hitherto in the majority of cases. The countersinking of set screws in all revolving parts is an example of what might be done. There has been, as a matter of fact, a great improvement in the design of machine tools during the last 15 or 20 years. But much remains to be done. Each new process and each new material employed in industry bring with them their

[1] The first article of this series appeared in THE LANCET of Feb. 9th, 1924, p. 304.

own special risks for health and safety; thus, the use of celluloid obviously requires special safeguards against the danger of fire.

The outstanding change in the last 20 to 30 years has been the use of electricity both for lighting and as a motive power. There were 107 electrical accidents reported in 1902, of which 4 were fatal; there were 309 reported in 1922, of which 17 were fatal. In this connexion the greatest number of accidents reported in any year was in 1914, when there were 415; whilst the greatest number of fatal accidents was in 1919, when there were 28. When one considers the huge increase in the use of electricity and the risks involved, these figures seem to point to a very considerable measure of success in combating the dangers. The special electrical inspectorate of the Factory Department of the Home Office dates back to 1902, and the elaborate code of regulations came into operation in 1909. Whilst the growth in the number of accidents has fallen far short of the growth in the use of electricity, and satisfaction in that is legitimate, it is yet clear from the annual reports of the Chief Electrical Inspector that many accidents occur, and that several lives are lost every year quite unnecessarily. Contractors sometimes put in inferior material to lower costs, and for the same reason the sub-stations of public authorities supplying electricity are often unduly cramped, and are therefore more dangerous to work in. But the chief cause of accidents is the ignorance or the foolhardiness of the workers. Unskilled men are put to work among dangers which they do not understand, and skilled men deliberately and unnecessarily take risks. "In these cases," wrote the Chief Inspector in 1922, "although the persons meeting with the accidents were themselves at fault, the real blame rested with the responsible management in permitting work to be done under similar dangerous conditions as a normal practice."

The Need for and Value of Warnings and Instructions.

Ignorance, foolhardiness, lack of proper supervision, are, indeed, everywhere among the chief causes of accidents. These can be dealt with by proper measures, and a great deal is being done by that most useful body the British Industrial Safety First Association to spread instruction and enlightenment as to them. The movement is a new one over here, except in the case of one or two well-known pioneer firms, but in America it has achieved an enormous reduction of injuries. There is needed in all works a safety committee of workers meeting regularly with the managers; and there ought to be one person whose special responsibility it is to watch the interests of safety; in large works he should probably be a full-time man and an engineer. A great deal depends upon the proper instruction of newcomers, especially of boys and girls, as to risks and precautions. What is needed afterwards is a steady stream of reminders by poster or bulletin, or by discussion in the shop committee. The methods of advertisement which din into us the merits of a hair-restorer can be applied usefully to impress upon a factory operative that she must keep her hair inside her cap or she will pay a visit to the ambulance room, and may have no hair left to restore.

Some remarkable results are claimed already for Safety First propaganda, as already in use. Of one big paper mills near London it is reported that "in 1920 their employees lost 4235 days through accidents, but in 1921 this figure was reduced to 1225½ days (or over 71 per cent.), though there was only a comparatively small decrease in the total number of persons employed and the total number of hours worked. This meant that not only was there a very big decrease for the workers, their wives and families, in suffering and possibly in permanent disabilities, but also that at least an additional £1200 was paid to them in wages." Any reduction in accidents means also, of course, a reduction in the amount of compensation paid, and it lightens thus a burden which falls first upon industry and ultimately upon the general public as consumers.

The importance of educational methods and of the full coöperation of the workers is shown by the fact that of all accidents reported to the factory department about one-third only are due to machinery, and Mr. Gerald Bellhouse, the Chief Inspector of Factories, estimates that of the remaining two-thirds not more than one-third could be prevented by better safeguards alone. It is interesting to note that the Departmental Committee on Accidents in 1910 was apparently prepared to relegate a large number of accidents to the category of "unpreventable." To-day we are beginning to prevent the "unpreventable" The work of the Institute of Industrial Psychology shows how much hope there is that we may be able to eliminate a number of accidents due either to some mal-adjustment of worker to his tools or materials, or else due to states of mind. In particular scientific vocational guidance is likely to prevent in the future the placing of large numbers of boys and girls in occupations for which by physical and mental make-up they are not well suited.

Risks from Bad Lighting and Fire: The Influence of Pace.

It came out very clearly at the Departmental Committee in 1910 that bad lighting is the cause of a great many accidents. Men stumble in passages and gangways and they may easily do themselves serious harm, especially if there should be scrap metal lying about. Whilst the Home Office has no power to prescribe adequate lighting in ordinary cases, it may do so where there is danger to life or limb; it is prescribed for about half a dozen industries where the dangers are most obvious—e.g., ship-repairing. The next Factory Act is almost certain to require "adequate lighting" as a general provision, and, moreover, power will be given in all probability for the requirement by special order of definite standards of illumination, measured in foot-candle, in different industries. Later on it is possible that a minimum illumination may be prescribed for different processes.

Provision for escape in case of fire is a distinctly weak point in a great many factories. The blame for this must rest partly upon the employers and the workpeople, partly upon the local authorities who have the main responsibility for making and enforcing regulations for safety in this respect. It is the duty of the local authorities to certify new factories to be provided with reasonable means of escape, and it is their further duty to inspect from time to time both new and old factories (except those employing less than 40 persons, and even as to them the local authorities can obtain powers) and to prescribe alterations if necessary. There can be no doubt that many of the smaller bodies do their work very badly; and even in a large city factories of recent erection are sometimes found with doors opening inwards and with other dangerous conditions. Even when a works has proper emergency exits, they are not infrequently blocked up by material or lumber, or it may happen that only a few of the workers know where these exits are. The prime responsibility here must rest with the works manager. Fire-drills at irregular intervals are the best safeguards. Two industries come under regulation as dangerous trades because of special risk of fire: they are manufacture of or with celluloid, and the manufacture of felt hats where inflammable solvent is used. In each case a very important regulation is restriction of the amount of material which may be handled in a given space.

Both the fatigue of long hours and the speeding-up of modern industry have been alleged as causes of accidents. With regard to the former, it would seem to be true of women, but not true to anything like the same extent of men. On the whole its importance as a cause of accidents appears to have been overrated. It is probable that there is more reason to connect a high accident-rate with the high speed of modern industry. Dame Adelaide Anderson, formerly principal lady inspector of factories, has commented on the comparatively few accidents occurring in philanthropic institutions, where the work is often more leisurely

though the guarding may be less efficient. But in the absence of statistics it is impossible to be at all certain. The relation, if any, between speed and accident-rate deserves a great deal more attention and scientific investigation than it has yet received.

The Need for More and Better Preventive Measures against Accidents.

The next best thing to preventing accidents is to have the means at hand for treating them promptly and properly. It is only in the last few years that the importance of first-aid equipment has been realised, and especially its value in preventing all sorts of small wounds from becoming septic, a frequent cause of unnecessary suffering and loss of time. First-aid has been for years past a requirement in the regulations for half a dozen "dangerous trades," but the danger guarded against in most cases was specific poisoning or infection—e.g., by chromates used in dyeing or by anthrax spores; apart from that, first-aid equipment, although not compulsory, has been generally supplied in docks and shipyards, at least in the largest centres. Under that Act it was made a requirement in a number of welfare Orders, covering, amongst other trades, all work at blast furnaces and in foundries, in iron and copper mills, and in other metal works. The new Workmen's Compensation Act makes the provision of a first-aid box compulsory in every factory, and it must be in the charge of a responsible person. Insistence on the need for the immediate treatment of even trivial injuries is also an important part of the Safety First Association's propaganda. They issue posters for display in works, with pictures of germs as large as lobsters, much in the style of infant welfare diagrams.

The general impression derived from a study, both of such statistics as are available and also of the measures taken for the prevention of accidents, is that nothing like the progress has been made in this direction which has been made in the prevention of disease. A good deal has been done to lessen the number of machinery accidents, but by far the greater number of accidents are not directly due to machinery. The most that can be said at present is that attention is again being focused on the very high accident-rate, and that measures are being taken, both under State regulation and as the result of private initiative and propaganda, which it is to be hoped will bring about in the next few years a marked diminution in the number of accidents.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

"Mensæ Medicæ."

THE appalling need which all the brain workers in Germany are experiencing, say Profs. Bier, Bumm, Czerny, His, Goldscheider, and other well-known members of the medical profession in Germany, in an appeal which they have just published in the *Tageblatt*, is being felt in an overwhelming measure by doctors. Large numbers of people are no longer calling in medical aid on account of their inability to pay the fees. This dwindling number of their patients has brought thousands of doctors to such a dire state of need that they have been obliged to seek other ways of earning a livelihood, and the majority of them are in a pitiable condition. Some have even been driven to commit suicide. This need might be mitigated if in the already-existing, or planned, community kitchens in Berlin meals for the doctors—"mensæ medicæ"—could be established. For these meals they should pay a small sum of money, or in certain exceptionally unfortunate cases they might be given free. Dr. Eugenie Schwarzwald has placed at the disposal of the profession the kitchens which were created and are conducted by the Austrian "Friendly Help." What is now wanted is money for carrying on the work in the kitchens and for buying the ood. Appeal is made to everyone who has cause for gratitude to the medical profession to send contributions to the credit of the "Friendly Help" (Department Mensæ Medicæ) at the Bank of Mendelssohn and Co., Berlin W. 8, Jägerstrasse 51; and by this means assist in maintaining the public health.

Bayer "205" in Sleeping Sickness.

Speaking before the Berlin Medical Society, Prof. F. K. Kleine, of the Institute for Infectious Diseases, gave a report of his expedition to Rhodesia and the Belgian Congo to prove the new trypanocidal compound in cattle disease and sleeping sickness. The members of the expedition numbered four, including a bacteriologist and a veterinary surgeon. Cattle disease, as Prof. Kleine explained, is produced by *Trypanosoma rhodiense* conveyed to cattle by *Glossina morsitans*, while sleeping sickness is caused by *Trypanosoma gambiense* and conveyed by *Glossina palpalis*. Some weeks are necessary to develop the virulence of trypanosoma within the glossina. In Rhodesia experiments were made with monkeys, some of whom, however, died from snake-bites. By injections of the compound the experimenters succeeded in keeping infected cattle alive and in a good state of nutrition even when bitten by numerous glossinas. They ascertained that Bayer "205" did not prevent infection, but that by reducing the potency of the virus it greatly modified the disease, so that the animals did not lose weight. In November, 1922, the expedition set out for the Congo where sleeping sickness is endemic. Prof. Kleine explained that there were three stages in sleeping sickness. First the stage of infection, then maniacal symptoms were manifested, and lastly a comatose stage set in. By injections of Bayer "205" the blood was nearly always rendered free from trypanosomes, but sometimes in apparently healthy persons trypanosomes were found in the spinal fluid. In Rhodesia 35 patients were given a subcutaneous injection of 1 g. on the first, the tenth, and the twenty-eighth day, the maximum being five injections. In the Congo 105 patients were given intravenous injections of 1 g. on the first, the third, and the thirteenth day respectively. In two patients only was the trypanosome found in the blood after treatment, and even very grave cases could be cured. Transitory albuminuria sometimes occurred. The percentage of definite cures cannot yet be given, but apparently an infected district may be made healthy by the destruction of trypanosomes in the blood.

Sterilisation of the Unfit.

Dr. G. E. Boeters, a district medical officer of health in Saxony, writing to the *Aerztliches Vereinsblatt*, the official organ of the Aerztevereins-Bund, draws the attention of the profession to the present degeneration of the German race, and in the interests of posterity he proposes the sterilisation of habitual criminals, psychopaths, and feeble-minded people by castration. He contends that already under the present laws this operation is permitted, provided the degenerate has been placed under a guardian and that the guardian has consented to the operation. Dr. Boeters had already made provision for such operations in the State Hospital of Zwickau, Saxony, which is under the direction of the well-known Prof. Braun, President of the German Surgical Association. Hitherto the operation had been performed on men only, and consisted in a resection of the spermatic cords; in the female a resection of the Fallopian tubes would be necessary. In the interest of the improvement of the German race Dr. Boeters advocates that children of school age who are blind, deaf-mute, or imbecile should undergo a sterilising operation. The cost of the operation would be met by the State. Permission to sterilise ought also to lie in the hands of guardians as well as of parents. Defective, epileptic, or insane adolescents who have been confined in an asylum ought, in Dr. Boeters's opinion, to be operated upon before discharge, and permission to marry should be given only after an operation has been performed. This penalty should be imposed on all persons who have committed crimes against public morality and

also on females with more than two illegitimate children. Criminals submitting voluntarily to the operation might be rewarded by the shortening of the time of imprisonment. These very radical proposals have been the subject of discussion in the above journal in which Dr. Juliusberger, a well-known alienist and advocate of abstinence, stated that similar principles had already been put into practice in Switzerland. Prof. Forel, in particular, had advocated the sterilisation of criminals and imbeciles. He also wished the method extended to habitual drunkards. Another correspondent, however, points out that the legality of such operations, even with the consent of the parents or the guardian, is not yet clear and that it is, moreover, very doubtful whether such eugenic operations would have any measurable influence on the race while economic conditions remain unchanged.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Unqualified Practice.

I RECENTLY wrote of Appenzell as the only Swiss canton where no medical degree is required for medical practice. In the canton of Glarus, where up till 1920 the same freedom existed as in Appenzell, a popular movement has recently been started with the object of returning to the former practice. An amendment to this effect, however, was vetoed by the cantonal council, the minority consisting of Socialists. With this the question is not settled as it will be brought before the referendum of the electorate. Behind the movement are chiefly herbalists and hydrotherapeutists. The canton of Glarus had good reasons to restrict medical practice to qualified men. Among the unqualified practitioners doubtful elements were frequent, and in the debate in the cantonal council the case of an ex-convict was mentioned. That these quacks have a very flourishing trade, which consists chiefly in postal treatment, is shown by a newspaper advertisement in which one of them put his practice on sale. "Daily income 300 francs, professional knowledge not strictly necessary," it ran in the advertisement.

Cancer Figures.

As in other countries the cancer problem in Switzerland presents a serious aspect. Dr. A. Renaud, of Lausanne, has lately dealt with it from the statistical point of view. In the last ten years 12·8 death cases of cancer to 10,000 inhabitants were recorded per year, or 1 death of cancer to 780 inhabitants. The cancer mortality is 8·9 per cent. of the general mortality and 14·1 per cent. of the mortality of persons above 40 years of age. In Switzerland both sexes have about an equal share in this mortality with a slight preponderance of the male sex. Dr. Renaud's explanation of this fact is that with women cancer of external organs, more easily accessible for diagnostic means, is more common. In Switzerland 73 per cent. of cancer in men belongs to the gastro-intestinal tract, and 50 per cent. in women. Dr. Renaud shows that the increase is confined to cancer of deep organs; he is therefore inclined to attribute the increase to more perfect diagnosis. Sarcoma and carcinoma bear the same relation in both sexes, cancer being 16 times more frequent than sarcoma. In Switzerland the absolute number of deaths from cancer is 4700 per year, from sarcoma 300.

Epidemic Disease.

For a considerable time small-pox of a very mild character has prevailed; no fatal cases have yet been reported. The cantons with compulsory vaccination are signally free from the disease. In order to stamp out the small-pox the Federal Council has issued an emergency order. After notification of a small-pox case all persons inhabiting the same dwellings or who have been in contact with the patient must be vaccinated. If the first small-pox case in a parish is followed within 14 days by another, vaccination of the whole parish or district must be performed. The Federal Government is paying half of the cost of these measures; responsibility for carrying them through rests with the cantonal authorities. In Zurich about 600 persons have been brought before the police courts on account of refusal to submit to compulsory vaccination. The average fine was 50 francs.

Last July the beginning of a rather serious outbreak of poliomyelitis anterior acuta was recorded. In August the total number of notified cases was 41, in September 33, in October 70, in November 47, in December 20. This marked the end of the epidemic, for in the New Year so far only four cases have been brought to notice.

Public Health Services.

MENTAL HOSPITALS SERVICE.

THE annual report of the *West Riding Pauper Lunatic Asylum, Wakefield*, for 1922 contains matter of considerable general interest, which is enhanced by the frankness and decision with which the medical superintendent, Dr. Shaw Bolton, states his opinions on certain points connected with asylum administration. Wakefield Asylum, which retains the old style title in spite of the present vogue for "Mental Hospital," accommodates 2000 patients, and is staffed by six medical officers, all of whom hold a diploma in psychological medicine, a circumstance for which there is probably no exact parallel. The whole of the nursing staff undergo compulsory training for the certificate of the Medico-Psychological Association. Unfortunately, however, only a small proportion of the nurses thus trained have entered for the examination. "This result is most discouraging for the medical and lay officers who are responsible for the lectures and demonstrations, and makes the whole present method of training, examination, and certification little better than a farce. I am personally satisfied that this result is due to the fact that the monetary benefit resulting from training and certification, compared with the increasing wage paid to anyone who succeeds in remaining on the staff, is not sufficient. I recommend that the difference in pay between trained and untrained members of the staff be increased by an arrangement whereby no member of the staff who has not passed the various examinations at the proper time receives any annual increment in wage whatever. At present, after five years of mere service, the wage increment is more than double the monetary benefit gained by a serious worker who has obtained the medico-psychological certificate." This information is of particular interest at a time when the training and status of mental nurses are under consideration, and it is to be hoped that some measure may be adopted which will induce mental nurses throughout the country to seek official qualification.

A summary is given of the pathological work done during the year. More than half of the examinations carried out were Widal reactions. This is explained by the fact that every new patient and every new member of the staff are submitted to this test: agglutination is obtained in from 10 to 20 per cent. of cases, and these individuals are regarded as possible carriers and treated as such. Stanley Hall, where mentally defective children continue to be accommodated, has obtained encouraging results, a number of the children having been taught to do farm and other work. The number of new cases at the out-patient department shows a decrease, a fact which Dr. Bolton attributes in part to hostile and unwarranted criticisms of the asylums which have been made of late, "which have probably caused many cases to seek treatment elsewhere at the hands of the numerous professional and quack psychotherapeutists who are at present flooding the country."

The annual report of the *Crichton Royal Institution, Dumfries*, for 1923 records extensive structural changes, including the erection of new female staff

quarters, and a range of glasshouses in the gardens, providing a supply of fruit for the growth of which the climate of Scotland is ordinarily unsuited. The office of pathologist, which had been vacant for some time, is now filled, and a large amount of varied laboratory work is being done. The proportion of voluntary boarders among the patients is, as usual, a high one, no less than 319 voluntary patients having been under treatment during the year. It is a somewhat remarkable fact that the death-rate among voluntary boarders is actually higher (at 11 per cent.) than among the certified patients (9 per cent.). The causes of death in the case of certified patients are detailed, but in the case of voluntary boarders they are not. Not only is there no mention of the causes of death in these cases in the medical superintendent's report, but the nature of the mental illnesses from which they suffered is indicated only in vague and general terms, and information as to these patients is excluded entirely from the statistical tables. These omissions, on which comment was made in THE LANCET last year, inevitably suggest that patients are being received on a voluntary basis whose mental state might be regarded by some as demanding certification. In any case, it is surprising that no comment on the high death-rate among these patients should appear in the reports of the visiting commissioners. Where voluntary boarders are received on so large a scale as to comprise fully one-half of the acute cases under treatment at any given time, the report of the institution should surely afford information as to these patients in the same form and detail as in the case of the certified. To demand such information is not to attack the voluntary status, or to suggest restricting its application, but rather to protect it from accusations in which such deliberate and pointed silence as this is bound to result.

The report of the *Stirling District Board of Control* for 1922 shows that the number of insane requiring treatment at the Stirling Asylum is increasing. Four of the admissions were attributed to methylated spirit drinking, a habit which is said to be spreading. Two patients were admitted as voluntary boarders, the cost being defrayed by their parish councils, an arrangement of which this is the first example. An outbreak of enteric fever occurred during the year. Among 200 agglutination tests performed with the object of identifying carriers, difficulty was experienced in interpreting the results in the case of ex-Service attendants owing to the persistent effects of army inoculations.

An account in the *Irish Times* of a meeting of the Committee of the *Grangegorman Mental Hospital (Dublin)* shows that an alarming increase in lunacy has occurred in that part of Ireland. Accommodation has to be found immediately for 500 additional patients, and it may be necessary to take over the North Dublin Workhouse for this purpose. It also appears that the Government is demanding further economy in expenditure, which will involve reducing the diet scale. Some feeling has been aroused by a request that demobilised soldiers of the National Army should be given preference in applications for the post of attendant. A member suggested that "the same facilities should be offered to the men who fought for Ireland and were now being released from the jails." The impression produced by the article is that lunacy administration in Dublin is proceeding under great difficulties.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj. and Bt. Lt.-Col. W. F. Tyndale to be Lt.-Col.

Capt. W. E. K. Coles to be temp. Maj. whilst empld. as Dep. Asst. Dir. of Pathology.

Capt. A. J. Horne retires, receiving a gratuity.

TERRITORIAL ARMY.

Lt.-Col. J. Miller, having attained the age limit, is ret., and retains the rank of Lt.-Col. with permission to wear the prescribed uniform.

Maj. L. A. Avery, having attained the age limit, is ret., and retains the rank of Maj. with permission to wear the prescribed uniform.

Maj. (Prov.) J. E. N. Ryan is confirmed in his rank.

Capt. P. R. Bolus to be Maj.

Capt. B. L. Davis, R.A.M.C., to be Divl. Adjt. 55th (W. Lancs.) Divn., vice Capt. A. E. Richmond, R.A.M.C., vacated.

Capt. W. V. Cavill to be Capt. for service with Haileybury College Contingent, Jun. Div., O.T.C.

Capts. G. Candler and G. F. Denning, having attained the age limit, are ret., and retain the rank of Capt.

Capt. H. G. Kilner ceases to hold a commn.

Lt. E. N. Cook, R.A.R.O. (S. Wales Bord.), is attached for duty with the Portora Royal School Contingent, Jun. Div., O.T.C.

Lt. J. C. MacKay (late R.F.A., T.A.), Lt. G. W. Elkington (late Devon R.), and Lt. C. P. Oliver (late R.W. Kent R., T.A.) to be Lts.

Second Lt. A. W. Sheath (late R.A.F.) to be Second Lt. for service with Berkhamsted School Contingent, Jun. Div., O.T.C.

TERRITORIAL ARMY RESERVE.

Capt. G. R. Girdlestone, from 3rd Southern General Hospital, to be Capt.

INDIAN MEDICAL SERVICE.

The King has approved the retirement of Maj.-Gen. C. H. Bowle-Evans, C.M.G., C.B.E., K.H.P., and Maj.-Gen. Sir G. G. Giffard, K.C.I.E., C.S.I., K.H.S.

Diwan Chand Datta, Mangalore Padmanabha Pai, Muthuswami Nata Rajan, Tonse Panduranga Rao, and Ponathil Balakrishna Kurup to be temp. Lts.

Capt. Bhairon Dayal relinquishes his temp. commn.

ROYAL AIR FORCE.

The following are granted short service commissions as Flying Officers: S. G. Gilmore and T. Glynn.

Flying Officer T. A. G. Hudson is promoted to the rank of Flight Lt.

ARMY DENTAL CORPS.

The first examination of lieutenants before promotion to captain, and captains before promotion to major, in the Army Dental Corps, will be held in October.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: TUBERCULOSIS GROUP.

A MEETING of the Tuberculosis Group Committee was held at 1, Upper Montague-street, London, on Jan. 18th. Dr. Neville Cox pointed out the desirability of uniformity in the arrangement of the annual reports of tuberculosis officers (T.O.) and medical superintendents of sanatoriums (M.S.) and the opportunities presented for collective research. Dr. E. Ward mentioned work that is being attempted in the West of England on the influence of marriage, pregnancy, parturition, and lactation on tuberculosis. It was decided that a subcommittee be formed to draft a scheme for standardising the headings and data of annual reports of T.O.'s and M.S.'s, also to suggest subjects for periodical collective investigation. Coöperation with the Tuberculosis Society, the Society of Medical Superintendents, and the Ministry of Health was regarded as essential. The following were appointed members of the subcommittee: Prof. Lyle Cummins, Dr. T. H. Peyton, Dr. Neville Cox, and Dr. E. Ward. Dr. Lissant Cox was also nominated. The Secretary suggested that an annual report on the work of the committee might be helpful, and Dr. Peyton advised also that a brief account of the meetings should be sent for publication to the medical journals. Payment to metropolitan T.O.'s for consultations at union infirmaries and the circulars thereon were discussed. The view was expressed that the Ministry of Health should be assured of sympathetic coöperation in the case of tuberculosis patients in Poor-law infirmaries, but that if smooth working in the future was to be secured, the conditions of service as regards responsibility, payment, &c., should be clearly defined. A resolution was passed that "The Group Committee is strongly of the opinion that probationary appointments of T.O.'s are undesirable and that the designation of tuberculosis officer should only be applied to medical men with adequate experience of tuberculosis work, such experience to be gained in or at an institution devoted to tuberculosis, and by post-graduate study." Dr. Ward reported that Dr. W. H. Dickinson, of Newcastle, had been nominated by the Society for the League of Nations Tuberculosis Scholarship. Further activities of the Group were discussed, including collective research, greater coöperation between various societies, propaganda lectures, and posters.

Correspondence.

"Audi alteram partem."

ELECTRONIC REACTIONS OF ABRAMS.

To the Editor of THE LANCET.

SIR,—The points about which Abrams's critics want satisfaction appear to be four in number, as follows: (1) accuracy of diagnosis, (2) reality of benefit derived from treatment, (3) exclusion of "suggestion" as the therapeutic factor at work, (4) reasonableness of interpretation of the phenomena. It may, at the outset of what promises to be a full consideration of "E.R.A.," be worth looking at the subject from a general point of view and deciding what must be the ultimate criterion of the work's value.

Accuracy of Electronic Diagnosis is generally held to mean correspondence of "E.R.A." findings with "clinical" (meaning also bacteriological) pictures. In other words an "E.R.A." diagnosis is judged accurate if from it the clinical picture can be correctly deduced. Accuracy in this sense, however, cannot be the chief measure of value. The value of clinical diagnosis depends essentially upon how it serves the purposes of prognosis and treatment. Similarly the value of "E.R.A." diagnosis must be gauged mainly according to these practical considerations; moreover, however interesting a general correspondence between "E.R.A." and "clinical" findings may be, it would be surprising to discover that they absolutely fitted in with one another; for they represent sets of observations on different planes. Knowledge that a patient is infected by the gonococcus does not enable us to conclude that the grosser clinical picture is that of arthritis, though it may be so. In the same way the "60" reaction of Abrams may mean a condition of the tissues often, though not invariably, associated with demonstrable streptococci. After all, why must a new conception of disease be condemned because it is not wholly intelligible from the standpoint of older conceptions? Depend upon it, a new idea will thrive or wither simply according as it proves useful or otherwise in helping the sick.

Benefit from Treatment must be judged impartially in comparison with that derived from other therapeutic measures. For this purpose, in order to satisfy everybody, "clinical" (rather than "E.R.A.") diagnoses, which are definite and have been agreed upon, must naturally form the basis of the investigation.

The *Exclusion of "Suggestion."*—There are few, if any, who will now maintain that "suggestion" can be absolutely and certainly excluded from any form of therapeutics—even if such were desirable, which it is not. Various indications, therefore, which lead us to think that "suggestion" is not the chief agent at work in Abrams's treatment, though very interesting, can never help us to reach a definite conclusion in this connexion. But there is one thing which can help us to do so—namely, a comparison of the effects on organic disease of Abrams's treatment plus "suggestion" with other forms of treatment plus "suggestion."

Interpretation of the Phenomena.—"Reasonable interpretation" of a diagnostic or therapeutic procedure has never been regarded in medicine as the sole index of that procedure's usefulness. Only those who can satisfactorily explain the working of all the measures they employ to help the sick can demand as a necessary vindication of Abrams's methods a complete explanation of the phenomena. Moreover, it is obviously easier for Abrams's critics to say there is nothing in his machines than for his students to furnish an adequate physical explanation of their action. Surely to deny facts which are at present not susceptible of a proper interpretation is to take up what history has proved over and over again to be a mistaken attitude!

General Conclusion.—There are not a great number of complex conditions, including proof of "accuracy" of diagnosis, which must be fulfilled before Abrams's methods can win for themselves a deserved recognition. There is only one condition and that is that the investigated results of his treatment turn out to be thoroughly good and compare favourably with those of other forms of therapeutics. This must be the final and ultimate test; and it is the test by which students of Abrams are quite prepared that his work shall be judged. It is noteworthy that the first reply to the criticisms of "E.R.A." lately begun in the British medical press contains an offer to have the results of treatment along one important line publicly investigated; and the spirit of this offer has but one significance—namely, that Abramsites desire only to maintain a faith based on reality.

I am, Sir, yours faithfully,

Beckenham, Jan. 26th, 1924. J. KENELM REID

To the Editor of THE LANCET.

SIR,—I have no wish to trespass on your valuable space by writing any lengthy comment on the humorous article by Dr. Howard Humphris in THE LANCET of Jan. 26th on the electronic reactions of Abrams; as he says, his information is mostly secondhand. I am, moreover, not in the least desirous of raising any defence of the E.R.A.; I am quite content to let them stand or fall, being judged by their results.

But if Dr. Humphris, or anyone else who would care to test the accuracy of the statements made in this article, cares to put to the proof the statement "with our own knowledge of electricity it would appear to be impossible for any electric current in any form to pass from the intake . . . to the patient," I shall be delighted to give him an opportunity of doing so, on the understanding that he informs you of the result, with a view to its publication in THE LANCET.

I am, Sir, yours faithfully,

JAMES B. TOMBLESON.

Crowstone-road South, Westcliff-on-Sea,
Jan. 26th, 1924.

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 19th you report the demise of Dr. Albert Abrams of San Francisco. In your next issue Dr. F. Howard Humphris relates many details which the lay press have already presented to the public. Because this article on Abrams's Electronic Reactions is only further pabulum for the highly sceptical to laugh over, I scarcely observe anything in the coincidence of these two insertions which upholds the fair honour of our profession, unless it is to open up a discussion on behalf of an enthusiastic and original colleague who has not lived to exonerate himself.

When we had the amazing discovery laid before us by Prof. Rutherford regarding the electrical properties of the atom, we gaped in admiration. Because these investigations were conducted in a truly scientific manner, we did not have sensational lay press reports to depict lurid possibilities as each step was improved upon. Because Abrams lived in a country of advertisement is it not probable that the lust for the sensational had eclipsed the desire for truth? Unless Abrams had succeeded where others had failed, clinically, this natural consequence of jealousy and contempt would not be so apparent amongst his countrymen.

The conclusion that a fair and open mind can easily come to in this country is that "Abrams was the originator of a research into strange phenomena about which we know little." After a study of the various modifications of his instruments one finds that all his followers and "off-shoots" obtain precisely similar phenomena. There are other instances known where observers have noted these same phenomena from different standpoints. Precisely similar abdominal areas dull to percussion *can* be demonstrated on the

human subject when the subject is exposed to the oscillations of a wireless aerial. These areas stand out so decidedly from the surrounding resonance that here we have a phenomenon from which to set out on a criticism of the findings of our dead colleague.

Until an obvious phenomenon of this nature can be explained on a scientific basis we have no right, as sportsmen, to pick out what is immaterial from a dead enthusiast's discoveries. There is too much unscientific data in our own empiricism to justify such an attitude. It is of no ultimate value to science to have the failures of a pioneer pointed out to us. Was there anything fair in sending Abrams a specimen of a rooster's blood with the intention of deceiving him? In this profession of ours we even sign an oath against foul play! It is only an expert who can detect a spurious Bank of England note always. Our advanced position in science gives us a wide view of our ignorance. We cannot blame Abrams for not being an expert, but it is easier to deliver a judgment on the man who delivers the spurious note and hilariously publishes the nefarious result. Somehow it seems far removed from even a scientific intuition.

I am not writing primarily to praise Abrams, but to support the sentiment of the younger generation of our profession. That sentiment is so pleasantly devoid of a besodden sense of prejudice, and is so refreshingly imbued with a desire for scientific investigation into every new roadway which can ennoble our calling, that we are not happy to be left with only one side of a new investigation. Because Dr. Humphris was so fair as to say that his article was not a criticism it is disappointing to observe that he did not dwell on any case where Abrams's methods had preceded definite clinical improvement. It is investigation of this latter nature which will maintain that high standard of respect which the younger readers have for THE LANCET. Such investigation will undoubtedly stimulate interest in the subjects you consider to be worth bringing to our notice.

I am, Sir, yours faithfully,

WM. R. MCCRAE.

Montpelier Rise, London, N.W., Jan. 26th, 1924.

THE EXPLOITATION OF NURSES.

To the Editor of THE LANCET.

SIR,—It ill becomes anyone in the position of Dr. E. Cautley to level accusations and make such sweeping assertions on matters connected with the Nurses Registration Act and its administration by the General Nursing Council, as it is very obvious he is ignorant of the provisions of the Act. May I suggest he studies the Act with the rules and regulations as passed by Parliament, and I imagine he will realise most of his criticism is wide of the mark and quite uncalled for.

Dr. Cautley would make it appear that one examination is required for which a fee of 5 guineas is demanded, whereas two examinations—preliminary, after the first year's training, and a final, after three years—are included in the charge. Out of the 2 guineas charged for the preliminary examination, 1½ guineas is earmarked for payment of examiners, leaving the balance for all overhead charges, such as staff and office upkeep, printing, rent of premises hired for holding examinations all over the country, invigilators, travelling expenses of examiners, &c. The final examination will likewise be a very costly affair, and personally I do not consider the fees will meet the overhead charges. The General Nursing Council have followed the methods adopted by various examining bodies, such as the University of London, in their endeavour to carry out the provisions of the Act with regard to examinations, and when the number of centres in which examinations require to be held is considered it will be realised the examinations cannot be conducted at a lesser fee. Already I have heard of medical men questioning whether it is worth their while to act as examiners, as in their opinion the remuneration would be inadequate.

"Women paying such fees," states Dr. Cautley, "should have some voice in the matter," but surely he is aware that two-thirds of the Council is composed of nurses elected by nurses themselves, the remainder being medical men and members of the lay public, all appointed by the Privy Council, Minister of Health, &c.

I need not enter into his other arguments, but would like to assure your readers the General Nursing Council have no desire to make a profit out of examinations, but they must of necessity ensure that expenses are met, and if it is found that the examinations can be conducted cheaper than contemplated, then undoubtedly the fees would be revised accordingly.

I am, Sir, yours faithfully,

R. DONALDSON,
Chairman of Finance Committee, General Nursing Council.

Hinde-street, Manchester-square, W. 1, Feb. 9th, 1924.

To the Editor of THE LANCET.

SIR,—The letter from Dr. Edmund Cautley in your issue of Feb. 9th appears to me to state the case exceedingly well. As far back as Oct. 25th, 1923, I wrote myself to the Registrar of the General Nursing Council as follows:—

"Thanks for your reply to my letter of the 23rd instant. I am afraid that so far as we are concerned your Council's decision as to examination fees practically settles the case for us, as it will do for a good many more hospitals. Speaking personally, I do not think for a moment that there will be any enthusiasm whatever on the part of fever nurses at any rate to qualify for inclusion of their names upon the Council's register at a cost of 5 or 8 guineas in examination fees in addition to the fee for registration, since they simply cannot afford that amount of money. I am sorry indeed because I am most anxious to see the establishment of a reliable register, but I am very much afraid that its success will be gravely prejudiced by the high fee your Council has decided upon. Under the circumstances, I hardly think it is of any use our offering to coöperate in the examinations."

I am, Sir, yours faithfully,

H. KERR,
Medical Officer of Health; Medical Superintendent, City Hospital for Infectious Diseases.

Health Department, Town Hall, Newcastle-upon-Tyne, Feb. 11th, 1924.

SMALL-POX AND VACCINATION.

To the Editor of THE LANCET.

SIR,—Dr. C. K. Millard's criticism of Dr. J. C. McVail's address on the above subject is clever but not convincing. It is amusing to read in it accusations of special pleading (among other things) when the whole criticism is nothing more than a piece of special pleading for Dr. Millard's pet theory that infant vaccination is an error because modified small-pox masks the disease. For this theory he has to make two assumptions: (1) That natural small-pox is always so severe that it is immediately diagnosed. He should know perfectly well that this assumption is unwarrantable. (2) That modified small-pox is always so mild as to be missed; also an entirely unwarrantable assumption.

Dr. Millard will find it difficult to persuade us that the immunisation of a large and susceptible section of the community for even a temporary period—i.e., generally for nine to ten years, frequently for longer—has had nothing to do with the reduction in the incidence of small-pox, or that in the event of a small-pox outbreak a mass of vaccinated and revaccinated persons is other than an invaluable barrier against the spread of the disease. There are other criticisms to be made.

1. He forgets to mention that, in the Poplar epidemic, two unvaccinated children lost their lives, both preventable deaths if infant vaccination had been practised. What would happen if small-pox of a virulent type were to be introduced into an unvaccinated infant school? Would Dr. Millard be satisfied with "isolation and surveillance of contacts" then? Yet this is what occurred in pre-vaccination

days and has done since (vide the Gloucester epidemic 1895).

2. He omits to mention the special circumstances under which Germany has been placed as regards the importation of infection since 1917. Can he let us know how many of the small-pox cases since 1917 were German citizens who had been twice vaccinated? Until we get this information and some accurate report of the epidemics, then Dr. McVail's adjective of "interesting" is still the correct one, and "disconcerting" must still be applied to the case of Germany before 1917 from the anti-vaccinists' point of view. It would be instructive to see Dr. Millard dealing with the conditions which prevailed in Germany by his methods of isolation and surveillance of contacts.

3. Dr. Millard is advancing in his views, for he is now even prepared to regard the vaccination of contacts as not essential, although in an airy kind of way he talks of it as being "valuable to prevent secondary cases." I wonder in how many towns the medical officer of health can exercise any adequate surveillance of contacts in a small-pox outbreak; and this from Dr. Millard, who in the Leicester epidemic of 1903 vaccinated about 800 contacts. The "modern" methods of control of small-pox, according to Dr. Millard, are isolation and surveillance of contacts. Then I say good luck to the medical officer of health who relies on them. In other words, the good luck of Leicester and not of Gloucester. As far as the experiment of Leicester is concerned, which after all is an experiment in taking risks with child life, Dr. Millard was very adequately replied to by Dr. McVail in "Half a Century of Small-pox and Vaccination." The reply still holds good, and Dr. Millard's case remains the same—a very weak one.

4. We are not quite sure whether the American type of small-pox breeds true, but in any case few medical officers of health would view with any degree of pleasure their districts in the condition of the City of Gloucester last year, and in which other districts are placed this year. Surely all this is not due to the incompetence of medical officers of health. Dr. Millard's other criticism that Dr. McVail's remarks might mislead the Members of Parliament speaks little of Dr. Millard's opinion of the intelligence of the latter. I do not know if Dr. Millard's criticism is intended for publication as an anti-vaccination pamphlet, but one can hardly consider it as a scientific criticism of Dr. McVail's address; why not have published it in the *Vaccination Enquirer* and not THE LANCET?—I am, Sir, yours faithfully,

A. H. G. BURTON,
Medical Officer of Health, Ilford Urban District Council.

Feb. 9th, 1924.

To the Editor of THE LANCET.

SIR,—Dr. Killick Millard has made his position clear. He believes vaccination produces immunity, though he qualifies this statement by the word "temporary," whatever that may mean. Vaccination, he agrees, can prevent doctors, nurses, and contacts developing small-pox, and when successfully performed in babyhood confers some sort of "temporary" immunity, since for periods, varying from a year or two up to 50 or more, it retains its influence by either keeping the subject immune from the disease, or so modifying it that, if he should be so unfortunate as to catch small-pox, he *may* escape death and disfiguration, not know what is the matter, and give the disease to others whose parents did not believe in modern ideas of immunity at the time they were born. These being his views on the efficacy of vaccination, the question of its application to the infantile population seems to rest on other than medical grounds.

Having taken much trouble to convince us that he is at one with the medical profession in their view that vaccination can protect the individual, he next propounds the extraordinary view that it cannot protect the community, as if the latter were some quite distinct entity, and were not made up of individuals. Such an argument makes one sit up and rub one's eyes to make quite sure that one is not in some land of dreams which defy all logic. Further, Dr. Millard is practically asking the individual to sacrifice his life and personal appearance for the sake of the community. "Please do not get vaccinated, because if you get small-pox it may be so mild that you may recover unscarred, and no one can be sure that you have had the disease." I can imagine the reply of the ordinary adult to such a proposition, and if he should object, when of age, to make this sacrifice for the community, why should we place him in such a position when he is a helpless infant. Frankly, I do not understand the position. I can understand a person not believing in the protective power of vaccination, and for such a one to object to infant vaccination is quite logical. But to say that certain preventive treatment is effectual for the individual or a portion of the community, but not for the whole, is incomprehensible.

As for the modern methods, on which Dr. Millard lays so much stress—viz., prompt hospital isolation of patients, quarantine and observation of contacts—it would not do to vaccinate the latter, lest they might get mild small-pox and escape observation—and disinfection, they are neither very new nor very modern, but may better be described as old methods perfected along with our general improvement of public health administration. The most recent methods go far beyond these, and aim rather at the production of natural or artificial immunity by such methods as vaccination and inoculation, coupled with hygiene on physiological lines. The late war showed the extraordinary efficacy of such methods, and these in conjunction with the older ones of isolation and disinfection render the individual and community, to which they are applied, as nearly impregnable to infectious disease—where the infecting agent is known—as is humanly possible. In those diseases such as measles and scarlet fever, where the infecting agent is unknown, Dr. Millard himself has repeatedly called attention to the futility of those "modern methods" he lauds as so useful in small-pox.

If the nation be *not* prepared to allow themselves to become immune by nature's extremely slow, sure, and wasteful method of "natural selection," they *must* be prepared to interfere much more energetically with nature on the modern lines which science daily opens up to us, else infectious disease will never be completely under control till the ordinary "homo sapiens" dies out, and the race is superseded by a new subspecies of supermen, who through untold ages of natural selection have acquired immunity to all the ordinary infections which afflict us now.

I am, Sir, yours faithfully,

R. KING BROWN, M.D.,
Medical Officer of Health, Bermondsey.

Feb. 12th, 1924.

SYNCHYTRIUM AND CANCER.

To the Editor of THE LANCET.

SIR,—That synchytrian parasites pass through chromidial and cytic stages, which correspond with those of the alien bodies that are an inseparable feature of the common human cancers and sarcomas, was stated in an article published in THE LANCET in 1921 (vol. ii., p. 495) under the heading Protista and Disease.

During the past three months I have made a practical study of the *Synchytrium* of the common dandelion and I have found that in some cases, side by side with the well-known nucleated form, which is a conspicuous object in epiderm-cells, there is a dense chromidial form seen not only in the epidermis but also in cells of the mesophyll and even of the vascular bundles. That these dense bodies are a phase of *S. taraxaci* is proved on tracing their career by careful examination of leaves taken at different stages of the disease; they are destined to become sporangia, either in a sorus or of the resting type. In the latter

case much yellow or black pigment is formed from them. These bodies in their dense state, and also when they are expanded into sporangia, and in their new nuclei, capsules, &c. resemble the bodies I have described in various malignant and some other tumours; more especially in squamous epitheliomas.

I am informed that *S. taraxaci* is abundant in the neighbourhood of Aberystwyth from spring to October, especially during June.

I am, Sir, yours faithfully,

London, W., Feb. 2nd, 1924. J. JACKSON CLARKE.

COMMON INTESTINAL WORMS.

To the Editor of THE LANCET.

SIR,—With reference to Dr. William Nicoll's remarks in his paper on the Pathogenicity of Common Intestinal Worms in your issue of Jan. 26th, regarding the need of an up-to-date bibliography containing the more important clinical records of recent years, I may point out that reviews of recent work on the clinical aspects of intestinal parasites with bibliographies have been published by me in the following issues of *Medical Science:* Abstracts and Reviews: 1920, i., 401–4; 1921, iv., 103–9; 1922, vi., 280–7; 1923, ix., 91–6. It is noteworthy that of the 86 papers reviewed, most of which were written from the standpoint of general medicine, surgery, and neurology rather than of helminthology, only 4 had been published in this country, as compared with 26 in the United States, 26 in Germany, 15 in France, 4 in Switzerland, and the rest in other European countries, India, and Japan. Of the 26 American papers, the majority, as was to be expected, deal with hookworm disease, while the large number of articles published in Germany is to be attributed to the extraordinary increase in helminthiasis among all ages and classes of society in that country since the war owing to the prevailing lack of cleanliness and the predominance of a vegetarian diet (Müssig[1]). The recent, though less marked increase of helminthiasis in France, which has been strikingly illustrated by the fact that in the two years following the war one out of every three patients operated on in the Havre hospitals vomited an ascaris after the anæsthetic has aroused considerable interest in the subject, especially as regards the effects of the infestation on the nervous system. Several cases of meningitis have recently been recorded in France closely resembling tuberculous meningitis, not only in their clinical symptoms, but also in the character of the cerebrospinal fluid, the principal differences being the absence of tubercle bacilli and the rapid recovery after evacuation of the parasites in the meningitis caused by worms.

I am, Sir, yours faithfully,

J. D. ROLLESTON.

Grove Hospital, Tooting, S.W., Feb. 6th, 1924.

"AN INTRODUCTION TO SURGICAL UROLOGY."

To the Editor of THE LANCET.

SIR,—In a notice of my small book with this title (THE LANCET, Feb. 2nd, p. 237) your reviewer, while praising the soundness of the actual text, says that the author describes surgical urology "as a 'terra incognita to many practitioners' without justifying his criticism of his colleagues." The words I actually used were (page v.) "seems to be something of a terra incognita"; and they were based, not upon opinions formed by myself, but upon statements made to me by practitioners as to their own lack of familiarity with the subject. Thanking you for this opportunity of clearing myself from the charge of unfairly criticising any of my colleagues,

I am, Sir, yours faithfully,

Welbeck-street, W., Feb. 9th, 1924. W. K. IRWIN.

[1] Münchener medizinische Wochenschrift, 1921, lviii., 1395.

BLOOD-COMPATIBILITY OF MOTHER AND INFANT.

To the Editor of THE LANCET.

SIR,—I am in agreement with the views expressed by Dr. S. C. Dyke in his letter published in THE LANCET of Jan. 26th. When my paper appears, Dr. Dyke will see that there is little, if any, difference in our opinions.

I am, Sir, yours faithfully,

Liverpool, Feb. 4th, 1924. NORMAN B. CAPON.

Obituary.

SIR KENNEDY DALZIEL, F.R.F.P.S. GLASG.

Sir Kennedy Dalziel, surgeon to the Western Infirmary, Glasgow, died on Sunday, Feb. 10th, in his sixty-fourth year. A native of Dumfriesshire, he was born at Merkland, Penpont, in 1861. He received his early education at a private school in Dumfries and studied medicine at Edinburgh University, and qualified M.B., C.M. in 1883. He continued his medical studies in Berlin and Vienna, where he specialised in experimental surgery and pathology. On his return to Scotland he settled in Glasgow and there, little by little, won his way to the front rank among surgeons. In recognition of his prominent services in his profession, particularly during the great war, the King conferred the honour of knighthood on him in 1917. His first appointment was as house surgeon in the Royal Infirmary, and in 1885 he succeeded Sir William Macewen as casualty surgeon for the Central Division of Glasgow, a position which he retained until 1894. In 1887 he was admitted F.R.F.P.S. in Glasgow, by examination. Intimately associated with Sir William Macewen in the Royal Infirmary and with Sir Hector Cameron in the Western Infirmary, Sir Kennedy (then Dr.) Dalziel joined the staff of the Western Infirmary in 1899. He was also for a number of years senior surgeon to the Royal Hospital for Sick Children. His connexion with that institution began in 1891, and he held the appointment until the completion of the scheme for the erection of the new hospital buildings at Yorkhill, in which he took a very active part until it was brought to a successful conclusion in 1914. He was consulting surgeon to the Glasgow and South-Western Railway and to the City of Glasgow Fever Hospitals, and was medical referee under the Workmen's Compensation Act. As a teacher and demonstrator Sir Kennedy Dalziel had many natural gifts, enriched by a wide experience and applied with a sympathetic mind, which contributed in no small measure to the fame of the Glasgow Medical School. He was lecturer on medical jurisprudence and professor of surgery in Anderson's College, Glasgow, and lecturer on anatomy in the Western Medical School.

In his work as an infirmary surgeon and in his private practice, to which he devoted himself unstintedly, he won the esteem of an ever-growing circle, both through his outstanding skill as a surgeon, and through his personal charm and sympathy. His contributions to medical literature, which were considerable, dealt mainly with abdominal surgery[1] and showed the same concise grasp of his subject which characterised his lectures. He also contributed to the proceedings of a number of medical societies in Glasgow with which he was connected. For many years Sir Kennedy Dalziel was associated with the volunteer movement and later with the Territorial Medical Service, where he attained to the rank of lieut.-colonel. On the outbreak of war he was appointed to an important position in the direction of No. 3 General Hospital, Stobhill, and he also rendered valuable war service in many other directions. He was appointed a consulting surgeon to the War Office, and visited the hospitals in France.

[1] See THE LANCET, 1902, ii., 503.

As the son of a farmer, he had a natural bent towards farming and stock-breeding, which he carried out with enthusiasm on his estate of Nether Kinneddar, in Fife. This occupation, which became more than a hobby, claimed more and more of his interest in his latter years, and he was never happier than when on a round of his pastures or stalls with any expert friend.

Sir Kennedy Dalziel, whose funeral took place on Wednesday, Feb. 13th, from Glasgow Cathedral to the Necropolis, is survived by Lady Dalziel and by their family of two sons and three daughters. One of his sons is Dr. George Dalziel, surgeon, Glasgow, who served with distinction in the Royal Army Medical Corps in the war and gained the Military Cross.

WILLIAM CURTIS, M.R.C.S. ENG.

BY the death of Dr. William Curtis, at the great age of 87, on Feb. 8th, Alton, Hants, has lost one of its oldest, best known, and most respected inhabitants. He belonged to a family of medical men who had practised for several generations in the town and neighbourhood, and was known not only as a careful practitioner, but also as a naturalist and authority on geology; with the help of his brother, Dr. John Curtis, he gathered together a large number of most valuable specimens illustrating geology and other branches of natural history, which he presented to the town and which now constitute the "Curtis Museum." Born in 1836, he was educated at one of the Friends' schools, near London, and in 1855 entered St. George's Hospital as a medical student. He qualified in 1858 as M.R.C.S. and L.S.A., and returning to Alton joined his father in practice. In addition to a large private practice he held the appointment of parish doctor and also medical officer to many clubs. It was during his time that a cottage hospital was started and he took a prominent part in its promotion. He retired from practice in 1911. Apart from medical work he gave a large share of his time to affairs in the parish. For the Mechanics Institute he acted as curator of the museum after the death of his father. After extensive research amongst old documents, parish registers, and the Domesday Book, he collected a number of facts which he put together in "A History of the Town of Alton," which he supplemented later by a smaller volume on the "Surrounding Parishes."

He married, in 1874, Miss Annie Withycombe Farthing, a daughter of Mr. Henry Farthing, of Wodington, Somerset.

SOUTH LONDON HOSPITAL FOR WOMEN.—A urological department has recently been opened. Out-patients are seen at this department, 86–90, Newington-causeway, S.E., on Tuesdays, at 1 P.M.

BATH CLINICAL SOCIETY.—A meeting of this Society was held recently at the Royal United Hospital, Bath, Dr. W. P. Kennedy, the President, in the chair. Dr. R. Waterhouse read a paper on Heberden's Nodes, in which he reviewed the literature dealing with the relationship of these nodes to gout. He then described the findings in 66 cases of his own. He did not consider that there was any real connexion between Heberden's nodes and true gout. In his experience patients showing Heberden's nodes derived great benefit to their general condition from hydrotherapy. The nodes themselves were unaffected. The following cases and specimens were exhibited:—Dr. F. G. Thomson; (1) A case of syphilitic enlargement of liver and spleen which had almost cleared up on antisyphilitic remedies; (2) a case of encephalitis lethargica; and (3) one of cerebral embolus following mitral stenosis. Dr. C. A. Marsh and Mr. F. Lace: A case of old epithelioma of the right tonsil successfully removed by operation. Mr. C. Terry: (1) A case of lupus of the hard palate successfully treated by radium; (2) an X ray showing obstruction at the hepatic flexure which was found to be due to a cystocolic ligament. Mr. J. S. Levis: (1) A case of painful feet after gonorrhœa: (2) a specimen of an enlarged thymus from a child of 11 months who died under an anæsthetic. Mr. W. G. Mumford: A specimen of tumour of the left maxilla removed by operation. Mr. C. Kindersley: A specimen of carcinoma of the male breast.

THE PRESENT STATE OF KNOWLEDGE CONCERNING VITAMINS.

THE second edition of No. 38 in the Special Report Series of the Medical Research Council,[1] issued five years after its original publication, is a document of importance in more than one respect. The personnel of the Committee which drew up the 1919 report remains unaltered, except that three names—Mr. W. B. Hardy, Dr. A. W. J. MacFadden, and Prof. C. J. Martin—have been added to it. The fact that additions to the report are more numerous than revisions, and that the masterly introduction to the subject remains almost unchanged, indicates that the mass of work published since 1919 has not materially altered the conception of vitamins set out so clearly in the first edition. As is pointed out, the monograph first appeared at a time when the importance of vitamins was by no means universally recognised. Some critics felt that, in any case, the claims made by the writers of the monograph were too extensive. Those, however, who possessed first-hand acquaintance with the observations and experiments which formed the basis of the statements made were not of this opinion. They were then relatively few; they are now very numerous. Instead of being, as then, almost confined to this country and the United States, actual investigators of the facts are now to be found in nearly every civilised country. Advances have been made, especially in our knowledge of the origin and distribution of vitamins, and the conditions which determine their stability. Much progress has been made also along lines which bring experimental studies into immediate touch with clinical observations and practical experience. The isolation of vitamins in a pure state, however, as yet remains unaccomplished.

The general plan of the monograph remains unchanged except in a few minor details. References do not now follow each chapter, but are more conveniently collected at the end of the book. Vitamin A has now a chapter to itself, following the chapter recording early experimental work on the differentiation of vitamins, which, being mainly historical, has suffered but little change in this edition. Beri-beri and scurvy are dealt with in separate chapters, with vitamins B and C respectively, and the chapter on rickets as a deficiency disease is brought forward to follow these from its former position after the discussion on the Application of Experimental Work to the Practical Problems of Human Diets. This discussion is divided into two sections as before, the relation of vitamins to the dietetic problems of adults differing widely from their paramount importance in the nutrition of infants.

The discussion of pellagra, provisionally included in the first edition among the diseases possibly due to a vitamin deficiency, has been omitted from the second edition. The reason for the omission is that while pellagra must still be regarded as a disease of dietetic origin, no fresh evidence has been brought forward in support of that view, and the latest researches upon the subject point to a quantitative or qualitative defect in the protein of the diet as playing the chief part in the ætiology of this disease.

The influence of diet on teeth is discussed in a brief final chapter. The report has been edited by Prof. A. Harden, F.R.S., to whom the thanks of the Committee are extended.

Vitamin A.

It is admitted that in the present state of our knowledge the nomenclature of the fat-soluble vitamin or vitamins presents some difficulty if confusion is to be avoided. In this report the term

[1] Report on the Present State of Knowledge concerning Accessory Food Factors (Vitamins). Compiled by a committee appointed jointly by the Lister Institute and the Medical Research Council. Second edition. H.M. Stationery Office. *1s. 6d.*

"vitamin A or fat-soluble A" is used to denote the accessory food factor necessary to promote growth, and prevent and cure xerophthalmia (in rats) upon a diet adequate in all other respects. The distribution in natural foodstuffs of this vitamin, its origin and physiological significance, its properties, and the attempts made at its isolation form the substance of Chapter III. While the antirachitic vitamin appears to have a similar distribution to vitamin A, the former term is here used to define a fat-soluble vitamin especially concerned with the calcification of bone, and the properties of this antirachitic vitamin are discussed in Chapter VI. on Rickets. All that is definitely affirmed is that an antirachitic vitamin similar in many respects to vitamin A is a central factor in the machinery of rickets; and the nomenclature outlined above is adopted provisionally and without prejudice to the question of the actual existence of two or more distinct fat-soluble vitamins.

Much work has been done since the issue of the original report on the distribution of vitamin A. The primary sources of this vitamin are found to be in the green leaves of plants and in marine algæ, which are now, with butter, cod-liver oil, colostrum, cod roe, yolk of eggs, and marine diatoms, credited with three crosses, as rich sources of this vitamin. In view of the preference of some veterinary surgeons for unpurified oils, the statement that there is no foundation for the belief that dark-coloured oils contain more vitamin A than "white" oils is of interest. The vitamin content of butter, cream, lard, mutton and beef fat, and milk varies with the diet, breed, and management of the animal from which these are derived. Great interest is attached to the origin and function of the large stores of vitamin A found in the liver of the cod and of many other fish. Fish, like mammals, probably derive the whole of their vitamin A either directly or indirectly from the vegetable kingdom. Investigation has shown that a marine diatom (*Nitzschia closterium*, W. Sm.) is capable of synthesising the vitamin when grown in sterilised sea-water in the light, and further that the concentration of vitamin attained in these organisms is very high. Many other marine algæ also contain the vitamin. These vegetable organisms are not directly devoured by the cod, but form the food of a host of minute animals (copepods, amphipods, larval decapods, and mollusca), which in their turn are eaten by many kinds of small fish and other marine animals, salps, squids, and certain molluscs, and these finally are taken by the cod and other fish. In the cod the vitamin is not confined to the liver, but in the period preceding spawning is found in considerable concentration in the roe, both hard and soft, daily doses equivalent to 0·025 g. and 0·05 g. respectively of the fresh soft and hard roe being sufficient to cause resumption of growth in rats. These amounts should be compared with the 0·2 g. of butter fat and 1–2 mg. of cod-liver oil required for the same purpose.

Isolation.—The greatest progress in this direction is afforded by the discovery that vitamin A remains in the unsaponifiable residue when the fat is hydrolysed in absence of air. When the cholesterol is removed by crystallisation or by precipitation with digitonin the whole of the vitamin is left behind along with the non-cholesterol fraction of the unsaponifiable residue, the exact chemical nature of which is not known. The close relation which exists between the presence of vitamin A in fats and the well-known reaction given by liver oils (the production of a purple coloration when the oil is dissolved in an organic solvent and a drop of sulphuric acid is added) has been pointed out. The intensity of the reaction was found to be roughly proportional to the vitamin-A content of a series of fish-liver oils. It is obvious that there is a close parallel between the two properties, but the necessity for caution is indicated by the fact that although the marine diatom *Nitzschia* has been shown to be rich in vitamin A, the oil extracted from this organism did not give the purple-colour test with sulphuric acid.

Vitamin B.

Though the identity of water-soluble B vitamin and the antineuritic factor are not absolutely established, it is now generally accepted; in this edition of the report they are provisionally regarded as identical. The tables indicating the distribution of this vitamin compiled from preventive and curative experiments on pigeons are mostly unchanged in this edition, but new observations confirming the high resistance to heat and to desiccation of this vitamin are recorded. As to the vitamin-B content of milk, discrepancies between the findings of Gowland Hopkins and those of Osborne and Mendel are recorded, the cause of the discrepancy not having yet been discovered. Attempts at isolation of this vitamin have not been successful. The power to synthetise the substance is possessed generally by plants. Yeast, as is well known, constitutes one of the richest known sources of this vitamin, but the question whether yeast synthesises the substance or merely absorbs it from the medium in which it is grown has not yet been decided, conflicting results having been obtained by different observers.

Vitamin C.

The classical history of the development of the conception of scurvy as a deficiency disease is again recorded and, indeed, can never grow stale. The histological changes in experimental guinea-pig scurvy are set out at some length in this edition, and illuminating diagrams of the changes at the rib-junction are reproduced from a paper published by F. M. Tozer.

The table indicating the distribution of vitamin C in foodstuffs is greatly extended, showing how much work has been done in this connexion since 1919. The substances now regarded as richest in this vitamin include raw fresh green cabbage leaves, swede juice, sprouted cow peas, grape fruit juice, lemon juice fresh and dried, naartje juice, orange juice fresh and dried, raw tomato, tomato juice (tinned). It is noteworthy that grapes have a very low antiscorbutic value. Tomatoes grown in South Africa were found by Delf and Pullinger (unpublished results) to be much less potent than those grown in England. Milk is by no means rich in antiscorbutic. Since fresh cow's milk cannot be considered as having a definite antiscorbutic value, its potency varying considerably with the diet of the cow, the weak point in the many experiments designed to investigate the antiscorbutic properties of various dried milks is that no comparison has been made between the anti-scorbutic potency of samples of the same milk before and after drying. It seems probable on the whole that dried milks of very varied potency are placed on the market, and no generalisation can be made on the subject. Spray process milks may possibly be less effective than roller process, owing to the greater opportunities for oxidation during the treatment.

Boiled milk has not been very thoroughly examined. The effect of pasteurisation on the antiscorbutic vitamin of milk, and in particular the relative effect of different processes, still awaits experimental investigation.

As to resistance to heat and oxidation, vitamin C is very sensitive to oxidising agents. The addition of either acid or alkali to the water in which vegetables are boiled appears to increase the loss of antiscorbutic property. Fruit juices may be dried without serious loss by evaporation in vacuo. The only important fact known about the origin of vitamin C is that it is produced during the germination of seeds.

Rickets.

The work on rickets undertaken since 1919 has been important but has not tended to simplify the problem of its ætiology. The present position is discussed under different headings and summarised as follows:—

Recent work on rickets has proved that there are two outstanding factors involved in the ætiology of this disease: 1. The amount of a substance (antirachitic vitamin) in the diet having similar physical properties and distribution to vitamin A. 2. The degree of exposure to sunlight. In addition, the American school of workers, as the result of

ork with rats, has laid great stress on the absolute and elative amounts of calcium and phosphorus in the diet. Mellanby, working with dogs, attached much importance o the amount and type of energy-bearing foodstuffs and nore particularly the amount and type of cereals eaten.

It is clear that both the antirachitic vitamin and sunlight re normally concerned in the deposition of Ca and P in rowing cartilage and bone. Animal experiments prove onclusively that they are capable of correcting deficient and nbalanced quantities of these elements in the diet and ringing about the formation of normal bone. Much of the ecent experimental work employing rats has centred round he influence of diets with a defective calcium-phosphorus atio. It is not clear, however, to what extent a faulty alcium-phosphorus intake, either from the point of view of bsolute or of relative quantities, is of practical importance n the causation of human rickets. Rickets develops in hildren even when ingesting a fair amount of cow's milk n which the amount of these elements is in excess of their equirements and the relative proportion satisfactorily djusted. In the case of diets consisting largely of cereals, owever, such is not the case, and, in this instance, defective ntake of calcium and phosphorus may well be a contributory ause of rickets.

The importance of the antirachitic organic factor in diet nd of exposure to light has been abundantly demonstrated oth by laboratory experiment and by clinical observation. od-liver oil, the richest known source of the antirachitic itamin, has been proved by well-controlled observations to ave a specific prophylactic and curative value. Similarly, ut to a less degree, milk, eggs, and butter have definite ntirachitic actions. Cow's milk and butter appear to show reat variation in their antirachitic properties, depending pon the diet and management of the cow. The point is ne of great importance and needs further investigation, ut our present knowledge indicates that pasture-fed cows —i.e., animals receiving fresh green food and exposed to unlight—produce a milk comparatively rich in both growth-romoting and antirachitic properties.

The question as to whether the antirachitic factor and itamin A are one or two substances is at the present ime under discussion. The points of similarity and dis-imilarity as regards their properties and distribution have een discussed. It cannot be said that unanimity of opinion n this matter has yet been reached. Sunlight and other orms of light radiation (mercury vapour lamp, carbon arc amp) have been shown to possess preventive and curative ffects on rickets comparable in many respects with those of od-liver oil. The interaction of sunlight and the anti-achitic vitamin has been described above. In infants nd in experimental animals sunlight acts in the direction f correcting the effect of an imperfect diet only if the lefects are not too severe. Thus the light radiation may be egarded either as an economiser of the antirachitic vitamin r as a mobiliser of reserve supplies in the tissues. Sunlight ppears to make safe some diets which are relatively deficient n antirachitic vitamin.

It is now intelligible why rickets is a comparatively rare lisease both in natives living under tropical conditions and n the inhabitants of the Arctic circle. The extra sunshine xperienced by the one set of people makes the smaller mount of calcifying vitamin in their diet do the work arried out by the larger vitamin intake of the Esquimo. People living in the temperate zone under modern industrial onditions of diet are often poorly supplied with both these herapeutic agents, and an intelligent application of the facts vhich have come to light as the result of recent scientific nvestigation may confidently be expected to result in the revention of one of the most serious diseases to which urban opulations are liable.

Diet of Adults and Infants.

The chapters indicating the application of experimental work to the diet of adults and infants have been extended in parts, notably the sections on osteomalacia and night-blindness, following on the work on the under-nourished population in Austria, Russia, and Japan, but their main conclusions remain unmodified. The final chapter on the influence of diet on teeth records the results of work by M. Mellanby on puppies, which, if it can be applied to humans, indicates that the correct feeding of women during pregnancy and of children during the development of the teeth should result in the production of teeth perfectly calcified and evenly arranged in the mouth. If, as seems likely, defectively formed teeth have less resistance to caries, the suggestion seems a natural one that one cause of the great amount of disease in the teeth of children is malformation consequent on bad feeding. Dental authorities have criticised this point of view severely, stating that examination of children has shown that only 3 per cent. possess hypoplastic or badly formed deciduous teeth, while 90 per cent. have teeth ultimately affected by caries. The examination which led to this result was, however, of a macroscopic nature, and M. Mellanby obtained microscopical results in 302 deciduous teeth of children, which appear to show a direct relationship between faulty structure and caries.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the Final Examination of the Conjoint Board held from Jan. 8th to Feb. 4th, the following candidates were approved in the undermentioned subjects, but are not eligible for diplomas :—

Medicine.—H. G. Anderson, F. Asker, and A. Barnsley, St. Bart.'s; P. Bauwens, St. Thomas's; R. Bolton, St. Bart.'s; W. R. Bowen, Middlesex; A. J. S. L. Boyd, St. Thomas's; Gwenddolen J. Brooke, Univ. Coll.; Doris D. Brown, Royal Free and St. Mary's; G. H. Buncombe, St. Bart.'s; Edna V. Butler, Bristol; Fanny L. Cattle, Univ. Coll.; J. Chronnell, Manchester; Edith I. Clark, G. E. C. Collis, and H. A. Cowan, Univ. Coll.; S. H. Currie, London; D. Davies, Guy's; D. V. Davies, St. Thomas's; E. C. Dawson, Birmingham; C. H. Devereux, Univ. Coll.; N. B. Dreyer, St. Bart.'s; E. F. Duck, Univ. Coll.; W. H. du Plessis, St. Thomas's; R. H. Dyer, King's Coll.; C. J. East and H. E. K. Eccles, St. Bart.'s; W. S. D. Elder, St. Andrews and St. George's; G. E. Ellis, St. Bart.'s; Marguerite Elnan, St. Mary's; T. P. Evans, Charing Cross; C. A. Francis, St. Bart.'s; Dorothy E. Galbraith, Royal Free; E. B. Garrett, Univ. Coll.; H. Geary, Guy's; W. T. McN. Gentle, St. Mary's; B. Green, Charing Cross; J. L. Griffin, Bristol; N. W. Hammer, Middlesex; J. Hartsilver, St. Bart.'s; L. B. Haye, Univ. Coll.; F. Heckford, St. Bart.'s; R. F. L. Hewlett, King's Coll.; Barbara J. Hick, St. Mary's; Barbara M. Hope, King's Coll.; L. W. Houghton, Guy's; Bessie G. Jemson, London; C. M. Jennings, St. Bart.'s; D. Jones, London; I. Kinsler, St. Bart.'s; J. H. Kok, Middlesex; J. H. R. Laptain, St. Bart.'s; Nancy R. Lewis, Royal Free and St. Mary's; D. T. Lloyd, St. Bart.'s; H. Lord, Univ. Coll.; W. J. E. Lupton, St. George's; E. M. McCausland, Middlesex; A. F. McGlashan, St. George's; G. A. McKaig, St. Thomas's; Lily C. MacKinnon, Charing Cross; R. B. McVicker, St. Thomas's; W. A. Mill, Guy's; J. B. Oldham, and D. U. Owen, Liverpool; G. F. S. Parker, Manchester; A. E. Parkes, St. Bart.'s; W. Parry-Jones, London; H. W. Pearson, St. Bart.'s; Winifred M. Proctor, Durham; G. Ralston, London; M. A. Rana, St. Mary's; H. D. C. Rice, King's Coll.; Lilian E. Robinson, Univ. Coll.; F. W. Roques, Middlesex; Kathleen Shelton, Durham; I. Spiro, Univ. Coll.; L. Statnigrosch, Middlesex; E. V. Suckling, London; G. E. F. Sutton, King's Coll.; Portia K. Taylor, Univ. Coll.; A. Tom, Guy's; G. M. Tothill, Charing Cross; J. R. Tree, Middlesex; Mary M. Turnbull, King's Coll.; C. A. van Rooyen, London; I. R. Vermooten, Guy's; Constance Walters, Cardiff; M. A. Weisman, Manchester; Mary A. Wiles, King's Coll.; G. Williams, St. Mary's; Dorothy Wood, Charing Cross; H. G. Wyatt, London; and Muriel M. Yates, St. Mary's.

Surgery.—S. Abadir, King's Coll.; H. G. Anderson, St. Bart.'s; J. H. Anderson, Manchester; H. Aukland, Liverpool; V. Barkin, St. Bart.'s; St. C. E. J. Barrett, Middlesex; Margarida R. Bensaude, Birmingham; A. G. Bewes, St. Thomas's; W. H. Bradley and R. J. Cann, Guy's; A. N. Coomarasamy, London; D. A. L. Crawshaw and J. C. G. Dickinson, Guy's; Kathleen H. Durance, Royal Free; H. S. Edwards, St. George's; Phyllis V. L. Epps, Royal Free; T. I. Evans, St. Thomas's; W. Evans, London; C. J. Fox, St. Mary's; F. G. France, St. Bart.'s; J. H. Francis, St. Mary's; A. G. D. Gavin, St. Thomas's; W. H. Gervis, Cambridge and St. Thomas's; J. F. Goodenough, Guy's; C. A. H. Green, St. Bart.'s; C. W. Healey, Liverpool; H. N. Hearle, Guy's; D. V. Hubble, St. Bart.'s; J. N. Hudson, Manchester; G. C. Hughes, Guy's; J. G. Hume, St. George's; W. S. Hunt, Guy's; A. G. Hyde, Sheffield; E. Jacobson, London; D. J. Jones, St. Thomas's; D. S. M. Jones and H. M. R. Jones, Middlesex; A. Jowell, Guy's; Dorothy L. M. Keats, Royal Free; D. E. Keefe and A. C. King, London; F. H. King, St. Bart.'s; M. C. H. Kingdon, St. Mary's; H. Levit and F. J. Levy, Guy's; K. S. Lim, Univ. Coll.; W. H. G. M. Line, St. Mary's; Elsa P. Lunn, Birmingham; D. M. Mackay, Middlesex; J. G. McMenamin and D. G. Martin, St. Bart.'s; F. Martin, Guy's; C. A. Moody, St. Bart.'s; G. O. Morgan, King's Coll.; Doris E. O'Doherty, Royal Free; K. O. Parsons, Guy's; E. A. T. Pateman, Charing Cross; T. Peirson, Manchester; A. Perkoff, London; D. B. Phillips and L. M. J. R. Pilot, St. Thomas's; E. B. Pollard and F. K. B. Quanbrough, St. Bart.'s; R. H. T. Rea, Cambridge and St. Thomas's; E. J. Rees, St. Thomas's; R. E. Robinson, Guy's; W. E. Rodgers, London; A. Sherning, Cambridge and St. Thomas's; A. D. H. Simpson, St. Bart.'s; A. E. Smith, Univ. Coll.; R. F. Smith, Guy's; G. G. Stewart, St. Bart.'s; H. Taylor and C. Thomas, London; O. F. Thomas, Manchester; W. G. Thwaites, St. Thomas's; D. S. Todd-White, Guy's; Hermione M.

Usborne, Royal Free; L. C. D. Van Der Borght, Ghent; Dorothy M. Vaux, Royal Free; J. L. le C. Walker and H. C. Warner, Guy's; J. L. Warner, Middlesex; W. Wilkinson and T. J. Wilson, St. Bart.'s; T. E. W. R. Wood, London; and Z. M. Yusef, St. Bart.'s.

Midwifery.—W. M. Abdel-Malek, Birmingham; H. M. Allen, McGill; C. A. Amesur, St. Thomas's; A. J. Amor, Middlesex; J. H. Anderson, Manchester; S. M. Anderson, Middlesex; E. C. Archer, St. Thomas's; F. Asker, St. Bart.'s; E. A. Aslett, St. Mary's; H. Aziz, Manchester; R. M. Barron and P. Bauwens, St. Thomas's; P. S. Bell, Westminster; R. J. I. Bell, St. Bart.'s; Margarida R. Bensaude, Birmingham; P. C. Bennison, Guy's; H. E. Blake, Guy's; W. R. Blunt, St. Thomas's; P. G. Brain, London; A. D. Briscoe, St. Thomas's; J. H. Broadhead, Guy's; T. H. P. Brooks, London; A. C. Brown, St. Bart.'s; D. M. Brown, Birmingham; G. A. H. Buttle and C. W. Carter, Univ. Coll.; J. Carver, London; T. E. Cawthorne, W. T. R. Chapman, and F. W. Charman, King's Coll.; M. N. Chatterjee, Birmingham; R. J. K. Chattey, Middlesex; Gwendoline Chave, St. Mary's; F. E. Chester-Williams St. Bart.'s; A. M. Claye and F. Clegg, Leeds; Doris M. Collins, Royal Free; L. C. Cook and W. S. C. Copeman, St. Thomas's; H. A. Cowan, Univ. Coll.; E. J. Creais and M. Cutner, St. Mary's; R. R. Dalling, Liverpool; S. H. Daneel, Guy's; H. E. Daniel, St. Bart.'s; A. F. C. Davey, Manchester; A. Davies, Middlesex; E. W. P. Davies and J. Davies, Westminster; S. C. Davison, Guy's; R. Y. Dawbarn, Liverpool; E. C. Dawson, Birmingham; Charlotta D. N. De Wilde, London; N. A. Dickinson, Manchester; J. M. Dobie, St. Thomas's; J. Dreadon, Otago; G. D. Drury, St. Bart.'s; Margaret H. Duncan, London; S. F. Durrans, Guy's; C. J. East, St. Bart.'s; A. B. Eddowes and H Scott-Edwards, St George's; J E. Elam, St Bart.'s; W. S. D. Elder, St. George's; O. M. Ellis, Cardiff; J. B. Ellison, St. George's; H. G. English, Univ. Coll.; G. I. Evans, Manchester; D. W. G. Faris, London; N. B. Farman, Charing Cross; W. J. C. Fenton, London; J. W. Field, Birmingham; F. E. Fox, London; D. B. Fraser, St. Bart.'s; T. M. Fripp, Guy's; C. J. Fuller, Univ. Coll.; F. F. Fuller, Liverpool; J. A. Galletly, Middlesex; M. Geaney, Sydney; N. C. Ghose, Middlesex; G. Gillett, Univ. Coll.; A. Glen and I. Gluckman, London; B. Green, Charing Cross; C. A. H. Green, St. Bart.'s; A. L. Greenway, King's Coll.; W. J. Griffiths, Liverpool; K. H. A. Gross, St. George's; Kathleen M. Halloran, Royal Free; J. F. Hamber, King's Coll.; C. L. Harding, St. Bart.'s; H. E. Hargreaves, Charing Cross; S. Harris, St. Thomas's; C. W. Healey, Liverpool; F. Heckford, St. Bart.'s; S. Helberg, Zurich and London; J. P. Helliwell, St. Mary's; R. F. L. Hewlett, King's Coll.; Barbara J. Hick, St. Mary's; H. Hinchco, Middlesex; L. W. Houghton, Guy's; J. N. Hudson, Manchester; Theresa H. Humphries, Royal Free; J. T. Hunter, St. Bart.'s; W. E. Hunter, Manchester; J. Hwa, Birmingham; A. G. Hyde, Sheffield; E. Jacobson, London; J. S. Jacobsz, Guy's; J. W. Jeffery, St. Mary's; Mary Jennings, Royal Free; C. W. W. Jeremiah, Middlesex; H. A. Johnson, Birmingham; F. M. L. Jones, London; Helen V. Jones, St. Mary's; L. E. Jones, St. Thomas's; R. M. Jones and A. Jowell, Guy's; D. L. J. Kahawita, King's Coll.; Dorothy L. M. Keats, Royal Free; G. W. Keele, Univ. Coll.; C. E. Kilmister, St. Thomas's; F. H. King and J. F. L. King, St. Bart.'s; J. G. Kingsbury, Guy's; P. H. Knowles, Bristol; T. C. Lewis, St. Bart.'s; K. S. Lim, Univ. Coll.; W. E. Lock, Middlesex; G. K. Loveday, St. Bart.'s; C. J. Lovering, Middlesex; E. S. S. Lucas, St. Thomas's; Elsa P. Lunn, Birmingham; Gladys E. McCabe, Royal Free and St. Mary's; J. McCunn, London; W. S. Macgowan, Middlesex; R. R. Mackenzie, Guy's; D. Magrath, Birmingham; J. R. Maleri, St. George's; J. L. B. Marais, St. Bart.'s; Evelyn D. May, Birmingham; L. M. Maybury, Univ. Coll.; Gertrude M. Mayhall, Leeds; B. A. J. Mayo, St. Bart.'s; S. P. Meacock, Guy's; A. W. C. Mellor, St. Bart.'s; J. D. Mills, Oxford and St. Thomas's; G. G. Milne, London; W. J. Montague, Guy's; J. G. Morgan, Univ. Coll.; C. A. Mulligan, Manchester; E. L. Newell, St. Thomas's; J. A. Noot, Cardiff; M. C. O'Connor, St. George's; Doris E. O'Doherty, Royal Free; G. C. B. Oliver, St. Mary's; L. J. Panting, Middlesex; W. E. C. Parry, Univ. Coll.; E. A. T. Pateman, Charing Cross; R. Paton, Middlesex; F. L. Patterson and Sybil de H. R. Pattison, London; R. M. Pearce and T. Peirson, Manchester; M. S. Pembrey, St. Bart.'s; J. E. Piercy, Guy's; K. F. Platt, Bristol; L. M. J. R. Pilot, St. Thomas's; G. H. Pitt, Guy's; L. Platzky, B. Policovsky, and T. B. Prys-Jones, Middlesex; C. Rankin, Liverpool; R. J. Rankin, Cardiff; F. C. Read, King's Coll.; W. Richards, St. George's; D. Riley, St. Thomas's; J. B. W. Roberton, St. Bart.'s; W. M. Roberts, Manchester; W. G. Roberts, Guy's; C. H. H. Robertson and G. R. Rolston, London; F. W. Roques, Middlesex; Alysoun H. Rowntree, Royal Free; Winifred M. Sampson, Univ. Coll.; H. B. Savage, St. Bart.'s; C. M. Scott, Charing Cross; S. Q. Servante, Middlesex; A. B. Slack, Manchester; K. S. M. Smith and J. S. Spickett, St. Bart.'s; A. A. Spiro, Manchester; R. Stanford, London; R. Stuart, St. Bart.'s; K. H. Tan, Middlesex; Catharine F. Taylor, Royal Free; E. W. P. Thomas, St. Thomas's; J. E. Thomas, Cardiff; W. S. Thomas, Univ. Coll.; F. S. Thornton, St. Thomas's; P. W. Tobin, St. Mary's; P. G. Trafford, T. G. Tresidder, and L. A. S. Trott, Guy's; E. J. Warburton, Manchester; H. A. Ware, St. Bart.'s; H. C. Warner, Guy's; R. L. Washington, Birmingham; M. A. Weisman, Manchester; Joyce E. M. White, London; V. E. Whitman, Cardiff; C. R. Williams, London; H. K. Williams, Guy's; R. E. Wolfendale, Manchester; J. Wood and H. M. Woodman, King's Coll.; G. P. Wright, Univ. Coll.; A. J. Wrigley, St. Thomas's; and H. G. Wyatt, London.

UNIVERSITY OF LONDON.—Dr. Charles Singer, lecturer in the history of medicine at University College and Hospital, will give three lectures, illustrated by lantern slides, on Mondays, Feb. 25th, March 3rd and 10th, at 5 P.M., in the large lecture theatre, University College Hospital Medical School, Gower-street, W.C. 1. The lectures are open to all students of the University of London, and the subjects are (1) the history of syphilis, (2) the history of plague, and (3) the history of small-pox and its relation to inoculation and vaccination.

A course of four lectures on Blood will be given by Prof. B. J. Collingwood at St. Mary's Hospital Medical School, on Thursdays, Feb. 21st, 28th and March 6th and 13th at 5 P.M. Attendance at this course is recognised in connexion with the B.Sc. (Hons.) degree in physiology. Admission is free.

MEDICO-LEGAL SOCIETY.—A meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., on Tuesday, Feb. 19th, at 8.30 P.M., when a discussion on the Law of Nullity of Marriage will be opened by Dr. S. Henning Belfrage, followed by Mr. H. W. Barnard.

ST. MARK'S HOSPITAL.—The eighty-eighth annual general meeting of this hospital was held at the Mansion House, London, on Feb. 8th, when an appeal was made for a balance of £12,000 for the extension of the hospital buildings in the City-road. This extension would enable the governors to provide another 21 beds and would also add to the accommodation for out-patients, 1184 of whom made 3951 attendances last year. Further information can be obtained from the Secretary, St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum, City-road, London, E.C. 1, to whom contributions should be sent.

MANCHESTER BABIES' HOSPITAL.—Post-graduate lectures at this hospital are being held on alternate Fridays until April 11th. To-day (Friday), Feb. 15th, Dr. W. Dyson will lecture on Fungus Infections in Children. On the 29th Dr. Catherine Chisholm will give a demonstration of the Treatment of Rickets by the Mercury Vapour Lamp, with Radiographic Illustration of Repair in Rachitic Bone. On March 14th Dr. Nesta Wells will speak on Infection in Infants' Wards. On the 28th Dr. C. E. Jenkins will discuss Vaccines and their Use in the Treatment of Infants, and on April 11th Dr. Chisholm will deal with Complications met with in the Treatment of Marasmic Infants. The lectures will be held at 5.30 P.M.

ROYAL SANITARY INSTITUTE: RECEPTION TO FOREIGN HEALTH OFFICERS.—The reception arranged at the Institute on Tuesday, Feb. 5th, for the medical officers visiting this country under the auspices of the League of Nations, proved a great success. Representatives were present from the Argentine, Austria, Czecho-Slovakia, Denmark, Ecuador, Esthonia, France, Germany, Italy, Latvia, Norway, Poland, Portugal, Roumania, Russia, Sweden, Ukrainia, and the United States of America. The guest were received by Sir John Cockburn and Dr. Louis Parkes, and among those present were four medical Members of Parliament, Dr. W. A. Chapple, Dr. L. Haden Guest, Dr. E. G. Spero, and Dr. J. H. Williams, three officers of the Ministry of Health, representatives of the League of Nations Union, Surgeon-Commander T. B. Shaw, R.N., Royal Naval College, Greenwich, and Mr. P. G. Blazer, secretary of the Labour Party Public Health Subcommittee. The medical officers spent a week in London visiting places of hygienic interest, and then divided into small groups to visit some of the large towns, returning to London in April.

MEDICAL SOCIETY OF LONDON: *Lettsomian Lectures, 1924.*—The syllabus of the Lettsomian Lectures on the Treatment of Pulmonary Tuberculosis by Dr. R. A. Young has now been issued. The first lecture, to be delivered on Feb. 18th, at 9 P.M., will deal with the history of the treatment of pulmonary tuberculosis; the nature and origin of the disease—variations in type; the principles of treatment and the forms of treatment available; and the choice of treatment for individual cases. Home, hospital, sanatorium, and climatic treatments will be discussed, also general management and diet, and the rôle of rest and of exercise. The second lecture on March 5th will be devoted to curative treatments: (1) Specific—tuberculin, serums, and vaccines; (2) chemiotherapy; (3) organotherapy; (4) mineral treatment; (5) physical treatments—heliotherapy, other light treatments and X rays, symptomatic and palliative treatments, managements of advanced cases, after care and vocational training. At the third lecture on March 17th mechanical and surgical methods of treatment will be discussed, including local limitation of movement; artificial pneumothorax treatment—indications and contra-indications; thoracoscopy and the method of dealing with adhesions; phrenicotomy; pneumolysis and apicolysis; thoracoplasty—its varieties, indications, and contra-indications; other surgical procedures; the rôle of surgery in the treatment of pulmonary tuberculosis.

HUNTERIAN SOCIETY.—The annual dinner of this ciety was held on Tuesday evening, Feb. 12th, at the otel Victoria, London, when Sir Bruce Bruce-Port r esided over a large and successful function, at which any ladies were present. Sir Humphry Rolleston, in ving the toast of the Hunterian Society, congratulated ie members on the rapid increase in their numbers, and ommended the principles under which the society was anaged as conducing to intimate interchange of views. Sir ruce Bruce-Porter replied briefly, and introduced, for the rst time in Hunterian celebrations, the personality of is. John Hunter, whose coöperation and sympathy were f such value to her husband in his arduous life. Mr. ohn Adams proposed the health of the Lord Mayor of ondon, who had, like previous Lord Mayors, shown much indness to the society, when Sir Louis Newton, in his ply, pointed out that the public health of the City was a gitimate source of civic pride. Dr. H. A. Ellis, speaking the toast of the sister societies, to which Sir William ale-White replied, made a stirring appeal for a real union etween the mother country and the dominions, his words eing received with great applause. Dr. Howard Humphris as brief and witty in his introduction to the company their guests, for whom Viscount Long, Mr. Justice orridge, and Mr. Hugh Edwards, M.P., replied. The inner closed with tributes to the President and Dr. ortimer Woolfe, the hon. secretary of the society.

PEOPLE'S LEAGUE OF HEALTH.—The Sims Woodhead series of ten weekly constructive educational ealth lectures are being held at the house of the Medical ociety of London, 11, Chandos-street, Cavendish-square, ondon, W. On Feb. 18th Prof. M. S. Pembrey will deal ith the Anatomy and Physiology of the Circulatory and espiratory Systems, and subsequent lectures will be given y Sir Frederick Mott, F.R.S., Sir Harry Baldwin, Prof. J. C. rummond, Dr. J. Mellanby, Sir W. Arbuthnot Lane, Prof. J. R. Kenwood, Mr. E. B. Turner, and Dr. A. F. Tredgold.

THE ENDOWMENT OF A HOSPITAL BED: THE OWER OF A FARTHING.—A farthing per week fund subscribed by employees in the Dunlop factories has produced 100 (96,000 farthings) to endow a bed in the Birmingham nd Midland Area Hospital for Children. The Council of ne Dunlop Hospital and Benevolent Fund, with whom the lea originated, have decided to use one-third of the arthings collected from their thousands of workers for rphanages and other charities, the remainder being devoted the endowment of beds in the various local hospitals. It hoped that within a few years the weekly offering of arthings will have enabled the fund to endow a bed in each Birmingham hospital. The idea might well be imitated by ther industrial undertakings throughout the country.

GLASGOW UNIVERSITY.—Sir Leonard Rogers, who is ecretary of the British Empire Leprosy Relief Association, elivered a lecture in the medicine class-room of the Univerity on Feb. 6th. The lecturer pointed out that the lepers f India were distributed in relation to the rainfall, except districts where the houses were not thickly aggregated, nd that this association was explainable on the assumption hat the bacillus required moist heat for its most favourable rowth. The modern conception of the disease was that was neither infectious nor hereditary, and only a trifling umber of those who lived in close association with lepers eveloped the disease. He then described the principle nderlying the treatment of leprosy by means of intraenous injections of the active principle of chaulmoogra il, in the form of the soluble salt, sodium chaulmoograte. similar lecture was given by Sir Leonard Rogers at the eekly luncheon of the Glasgow Rotary Club on Feb. 5th.

THE Glasgow Western Infirmary Resident's Club eld its annual dinner and meeting on Feb. 8th under he presidency of Dr. J. Galbraith Connal. About 70 old esidents were present.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—A linical meeting of this society was held in the society's hall n Feb. 7th, Dr. G. M. Duncan, the President, in the chair. Dr. W. F. Croll showed a case of congenital heart disease, nd briefly commented on the differential diagnosis of four roups of such cases. Prof. Ashley Mackintosh demontrated a case simulating carcinoma ventriculi, in which, owever, the blood count was more suggestive of pernicious næmia. Mr. Gordon Bruce showed a case of Charcot's isease, affecting the knee-, elbow-, and finger-joints. Dr. J. . Christie demonstrated a series of cases of skin disease hich included xanthoma multiplex in an infant: lupus rythematosus; dermatitis exfoliativa complicated by ityriasis; rubra pilaris; lichen planus annularis; ulcus odens superficialis; and an unusual form of lupus vulgaris.

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, FEB. 12TH.

PARLIAMENT reassembled on Tuesday, Feb. 12th.

Small-pox Outbreak.

Sir KINGSLEY WOOD asked the Minister of Health what steps he was taking to deal with the serious outbreak of small-pox in various parts of the country.—Mr. WHEATLEY replied: The responsibility for dealing with an outbreak of small-pox rests upon the local authorities and their officers. I may, however, say that at present there are only seven districts in which there is any considerable number of cases, and the medical officers of my department are rendering all possible assistance and advice to the authorities of the affected areas.

Supplies of Calf Lymph.

Mr. MARDY JONES asked the Minister of Health whether he was aware that private medical practitioners experienced difficulty in obtaining supplies of glycerinated calf lymph of the same guaranteed purity as that supplied to public vaccinators by the Ministry of Health; and, as many persons desirous of having vaccination or re-vaccination performed by their own medical advisers should have similar guarantees with regard to the purity of the lymph used by those extended to persons vaccinated by public vaccinators, would he take steps to secure the necessary powers to enable private medical practitioners to secure supplies of such lymph at a reasonable charge from Government sources.—Mr. WHEATLEY replied: As regards the first part of the question, I am advised that there is no difficulty in obtaining from reputable firms supplies of glycerinated calf lymph of reliable quality. The action suggested in the second part would involve a large and costly extension of the present Government supply which I am not prepared to recommend.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY, Burlington House, W.

THURSDAY, Feb. 21st.—4.30 P.M., *Papers to be read:* C. Tate Regan: The Morphology of a Rare Oceanic Fish, *Stylophorus chordatus* Shaw, based on Specimens collected in the Atlantic by the *Dana* Expeditions, 1920–22. F. P. Slater: A Sensitive Method for Observing Changes of Electrical Conductivity in Single Hygroscopic Fibres. (Communicated by Dr. W. L. Balls.) T. S. P. Strangeways: Observations on the Formation of Binuclear Cells. (Communicated by W. B. Hardy.) J. A. Crowther, Sc.D.: Some Considerations Relative to the Action of X Rays on Tissue Cells. (Communicated by W. B. Hardy.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Feb. 19th.

GENERAL MEETING OF FELLOWS: at 5 P.M.
Ballot for election to the Fellowship. (Names already circulated.)

PATHOLOGY: at 8.30 P.M.
Communications:
Dr. Marshall Findlay: Experimental Biliary Cirrhosis produced by Salts of Manganese.
Dr. S. C. Dyke: Some Observations on Aleukia.
Mr. A. H. Drew: Growth-promoting Substances and Embryonic and Tumour Extracts.

Wednesday, Feb. 20th.

HISTORY OF MEDICINE: at 5 P.M.
Papers:
Mr. J. E. H. Roberts: The History of Trusses.
Dr. Charles Singer: A Chinese Coroner's Handbook of the Thirteenth Century.

Thursday, Feb. 21st.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)
Cases:
Dr. Ernest Dore: (1) Case of Darier's Disease; (2) Case of ? Darier's Disease (previously shown).
Dr. G. B. Dowling (introduced by Dr. Barber): A Rare Lingual Condition.
Other cases will be shown.

Friday, Feb. 22nd.

STUDY OF DISEASE IN CHILDREN: at Guy's Hospital, at 4.30 P.M.
Cases will be shown.

EPIDEMIOLOGY AND STATE MEDICINE: at 8 P.M.
Paper:
Lieut.-Colonel A. J. Williams, R.A.V.C.: Analogies between Influenza in Man and Influenza in Horses.
A limited number of copies of the paper are available. Apply to Dr. R. Dudfield, Town Hall, Paddington, W.

COMPARATIVE MEDICINE.
Members of this Section are cordially invited to attend the above meeting.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Feb. 18th.—9 P.M., Dr. R. A. Young: (First Lettsomian Lecture) Treatment of Pulmonary Tuberculosis.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, W.
THURSDAY, Feb. 21st.—8.15 P.M., Meeting preceded by a Demonstration, by Prof. F. K. Kleine of Various Trypanosomes at 7.45. The paper will be read by Prof. Kleine on his Recent Expedition to Africa to investigate the action of "Bayer 205."

THE MEDICO-LEGAL SOCIETY, 11, Chandos-street, W.
TUESDAY, Feb. 19th.—8.30 P.M., Dr. S. Henning Belfrage will open a discussion on the Law of Nullity of Marriage, to be followed by Mr. H. W. Barnard, Barrister-at-Law.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, W.
FRIDAY, Feb. 22nd.—9 P.M., Prof. G. Elliot Smith: The Human Brain.

SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS, John-street, Adelphi, W.C.
THURSDAY, Feb. 21st.—8 P.M., at Essex Hall, Strand, Dr. Maude E. Kerslake: Why We Want Clinics.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
MONDAY, Feb. 18th.—5 P.M., Mr. C. P. G. Wakeley: Some Actions of Radiations on Living Tissues.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W. 1.
MONDAY, Feb. 18th, to SATURDAY, Feb. 23rd.—Combined Course on Diseases of Children. Clinical Demonstrations and Lectures from 10 A.M. to 4.30 P.M. daily, including the ROYAL WATERLOO HOSPITAL, VICTORIA HOSPITAL FOR CHILDREN, and PADDINGTON GREEN CHILDREN'S HOSPITAL.—CENTRAL LONDON OPHTHALMIC HOSPITAL. Clinical Lecture Demonstration every afternoon. Mon., 2 P.M., Mr. Oliver. Tues., 2.30 P.M., Mr. Gibb. Wed., 2.30 P.M., Mr. Neame. Thurs., 2.30 P.M., Mr. Cunningham. Fri., Mr. Williamson-Noble (Pathological).—LONDON LOCK HOSPITAL. Clinical work daily. Lectures at Dean-street as follows: Tues., 2.30 P.M., Mr. McDonagh: Clinical Demonstration with Exhibition of Paintings. Thurs., 2.30 P.M., Mr. Corbett: Interpretations of the Wassermann Reaction. 4.30 P.M., Mr. Abel: Some Complications of Gonorrhœa in the Male. Fri., 4 P.M., Mr. Abraham: Gonorrhœal Rheumatism.—LONDON SCHOOL OF TROPICAL MEDICINE. Tues., and Thurs., 2 P.M., Special clinical Demonstrations.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Feb. 18th.—10 A.M., Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Bishop Harman: Eye Dept. 2.30 P.M., Dr. Saunders: Medical Wards.
TUESDAY.—11 A.M., Dr. McDougal: Electrical Dept. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.
WEDNESDAY.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—11 A.M., Mr. Simson: Gynæcological Demonstration. 12 noon: Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
FRIDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 10.30 A.M., Dr. Pritchard: Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

ST. MARY'S HOSPITAL, Paddington, W.
THURSDAY, Feb. 21st.—5 P.M., Prof. B. J. Collingwood: First of four lectures on Blood.

ST. THOMAS'S HOSPITAL, Albert Embankment, S.W.
(In the Governors' Hall.)
THURSDAY, Feb. 21st.—5 P.M., Dr. J. A. Murray: Cancer. (First of four weekly lectures.)

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Feb. 21st.—4 P.M., Mr. Pitts: Oral Sepsis.

CANCER HOSPITAL, Kensington, S.W.
WEDNESDAY, Feb. 20th.—4.30 P.M., Dr. R. Knox: Recent Developments in Radiotherapy.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.
POST-GRADUATE COURSE: FEBRUARY–MARCH, 1924.
CLINICAL LECTURES AND DEMONSTRATIONS.
MONDAY, Feb. 18th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Epilepsy and Allied Conditions: Dr. James Taylor.
TUESDAY, Feb. 19th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Headaches: Dr. Risien Russell.
THURSDAY, Feb. 21st.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Poliomyelitis: Dr. Gordon Holmes.
FRIDAY, Feb. 22nd.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Surgery of Spinal Cord: Mr. Sargent.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.
MONDAY, Feb. 18th.—12 noon, Neurosyphilis, III.: Dr. J. G. Greenfield.
The fee for the Course, including Pathology, is £5 5s. For those who hold Perpetual Tickets the fee is £3 3s.

COURSE OF LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.
WEDNESDAY, Feb. 20th.—12 noon, Spinal Cord. Reflex Arcs. Automatism.
THURSDAY, Feb. 21st.—12 noon, Medulla and Pons: Dr. Kinnier Wilson.
The fee for this Course will be £2 2s.
Dr. F. M. R. Walshe will give A COURSE OF EIGHT CLINICAL DEMONSTRATIONS, CHIEFLY ON METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, in the Wards at 10 A.M., every Wednesday and Thursday during February. The numbers attending the Course will be limited. Fee £2 2s.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE NEUROLOGY OF THE EYES.
WEDNESDAY, Feb. 20th.—3.30 P.M., Optic Atrophy: Mr. Leslie Paton.
The fee for this Course alone is £5 5s. If taken in conjunction with the general Post-Graduate Course the fee is £3 3s. All applications should be sent to the Secretary, Medical School.
Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.
Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.
J. G. GREENFIELD, Dean of Medical School.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
THURSDAY, Feb. 21st.—5 P.M., Mr. C. White: Delay in the Second Stage of Labour.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
TUESDAY, Feb. 19th.—5 P.M., Dr. Haldin Davis: Ulcers of the Leg.
THURSDAY.—5 P.M., Dr. Griffith: Pustular Dermatoses.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)
MONDAY, Feb. 18th.—(At the Hospital for Women.) Dr. J. E. Gemmell: Pelvic Infection.
TUESDAY.—(At the Maternity Hospital.) Dr. Hendry: Some Points in Ante-natal Work.
WEDNESDAY.—(At the St. Paul's Eye Hospital.) Mr. Hayward-Bywater and Mr. Plummer: Pathological Conditions of the Lens.
THURSDAY.—(At the St. George's Skin Hospital.) Dr. Frank H. Barendt: Skin Cases.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES.
TUESDAY, Feb. 19th.—(At the Jessop Hospital.) 3.30 P.M., Prof. Phillips: Diagnosis and Treatment of Discharges.
FRIDAY.—(At the Royal Hospital.) 3.30 P.M., Dr. Skinner: Clinical Value of the Wassermann Reaction.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURES (at Whitworth-street West Branch).
FRIDAY, Feb. 22nd.—4.30 P.M., Dr. D. Dougal: Analysis of the Monthly Maternity Report and Remarks on the Treatment of Some of the More Important Obstetric Emergencies.

ANCOATS HOSPITAL LECTURES.
THURSDAY, Feb. 21st.—4.30 P.M., Dr. A. H. Holmes: Late Cardiac Complications of Rheumatism.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES.
THURSDAY, Feb. 21st.—4.30 P.M., Mr. R. R. Kerr: Diagnosis and Treatment of Chronic Abdominal Troubles.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
MONDAY, Feb. 18th.—4.15 P.M., Mr. S. R. Wilson: Recent Improvements in Anæsthesia.
TUESDAY.—4.15 P.M., Mr. E. D. Telford: Lateral Curvature of the Spine in Children.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Feb. 20th.—4 P.M., Dr. M. S. Paterson: Infectivity of Tuberculosis.

Appointments.

UTCHER, W. H., M.D., D.P.H. Oxf., has been appointed Assistant Medical Officer, Somerset County Council.

RNISS, ADA, M.R.C.S., L.R.C.P. Lond., D.P.H. Vict., House Surgeon, Nottingham Children's Hospital.

WIS, E. CATHERINE, M.S. Lond., F.R.C.S. Eng., Urologist to the South London Hospital for Women.

rtifying Surgeons under the Factory and Workshop Acts: MACKENNA, L. (Oakengates, Salop); IVES, B. G. (Newark); HETHERINGTON, G. M., M.B., Ch.B. Glasg. (Clackmannan).

Vacancies.

For further information refer to the advertisement columns.

berdeen Royal Hospital for Sick Children.—Hon. Asst. S.
irmingham General Hospital.—Director of V.D. Dept. £600.
irmingham, Highbury, Uffculme and Sorrento Hospitals.—Med. Supt. £800.
irmingham, Queen's Hospital.—Med. Reg. £100.
righton, New Sussex Hospital, Windlesham-road.—H.S. £50.

he Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Sherston, Wilts; Bodmin, Cornwall; Thornhill, Dumfries.

Births, Marriages, and Deaths.

BIRTHS.

AITHNESS.—On Feb. 6th, the wife of Dr. William Caithness, of George-street, Manchester-square, W., of a son.

HEELER.—On Feb. 4th, at North-street, Rugby, the wife of Dr. J. N. Wheeler, of a daughter.

DEATHS.

URTIS.—On Feb. 8th, at Alton, Hants, William Curtis, M.R.C.S., L.S.A., aged 87.

EWTON.—On Feb. 6th, John Newton, M.R.C.S., L.R.C.P., aged 72.

NELL.—On Feb. 5th, at Cecil-court, London, S.W., George Snell, M.D., late Colonial Medical Service.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

A "GRADED FACTORY" FOR TUBERCULOUS PATIENTS AND EX-PATIENTS.

BY C. F. PEDLEY, M.R.C.S. ENG.,
SENIOR RESIDENT MEDICAL OFFICER, WINSLEY SANATORIUM, NEAR BATH.

A SANATORIUM officer is interested in any views of working process on the care and after-care treatment of tuberculosis. In a paper on this subject read by Dr. F. J. H. Coutts at the ninth annual conference of the National Association for the Prevention of Tuberculosis, held at Birmingham in July, 1923, the point most emphasised was that the family of a tuberculosis patient must be taken as the unit in all schemes for care and after-care treatment.

Establishment of Diagnosis.

Probably many hundreds of patients pass through the hands of a sanatorium officer during his term of office, and where the institution is one for pulmonary tuberculosis he will of necessity have to deal with other forms of tuberculosis. In every instance he will have to consider the future of each patient, not only with reference to the individual's health, but also with regard to that individual's niche in the community outside an institution. As all sanatorium officers will acknowledge, all cases which pass through sanatoria are not suffering from tuberculosis, but 90 per cent. of these cases are probably labelled and notified as tuberculosis and are therefore handicapped for life.

In the present state of knowledge—among the general population and, I regret to think, among some members of the medical profession—tuberculosis is looked upon as a fell disease; in the latter case so much so that a patient with a positive sputum and in need of surgical treatment for some other cause is refused treatment in the general wards of a hospital. It is of the utmost importance that a difference should be recognised by everyone between a patient who has received sanatorium treatment for a condition not clearly distinguished and one who has received such treatment because he is suffering from tuberculosis. In many cases it is impossible to diagnose pulmonary tuberculosis at a dispensary or in a home: a patient suspected of pulmonary tuberculosis should be under observation for a length of time before a label is attached to his condition, and this can usually only be done in an institution.

A sanatorium should therefore be used much more frequently than it now is for purposes of diagnosis as well as for treatment of proved cases of tuberculosis: such use is allowed under the Ministry of Health's heading "Cases under Observation." Certificate "A" would not, therefore, be issued, as it so often is at present for every case because the patient is sent to a sanatorium. It makes a great difference to a patient who enters a sanatorium knowing that his case is only under observation, and that he may be passed out as not suffering from tuberculosis.

Definitely Tuberculous Patients.

We thus come to those patients who are definitely suffering with tuberculosis and these alone are the object of care and after-care treatment. To-day a tuberculosis patient after treatment is almost entirely maintained by charity, whether in a colony, on the staff of an institution, or in his home. His outlook is the same for the rest of his life, and there is no incentive to better his position. His labour tends to be exploited, his home goes to pieces, he may have lost his self-reliance, independence, hope; give these back to him and he is a new-made man. The treatment apparently most prevalent in sanatoria throughout this and other countries is the "graded work" system based on the theory of auto-inoculation. It is accepted by most tuberculosis authorities that by this method a person's resistance to active disease can be raised to and maintained at such a level that the individual can live and work for years if his outside circumstances allow it. The goal of all schemes for care and after-care treatment is to make these circumstances favourable, and I wish in this paper to lay the foundation of a plan to overcome the difficulties which surround the life of an ex-tuberculosis patient.

One gathers from Dr. Coutts's paper that much money is devoted by various bodies to the social and individual amelioration of the lives of tuberculosis patients outside an institution, and hardly any one scheme is similar to another. Every patient, whether he has been in a sanatorium or not, is, at the end of his treatment, in one of three classes: (1) fit for work, (2) fit for some work, (3) not fit for work. But a definite tuberculosis patient in Class 1, however fit he is, is never a 100 per cent. man in the world's market. Therefore he, together with his immediate circle, is affected from a social and economic point of view. Much more so

are the greater number of patients who fall in Class 2. I exclude from consideration those patients not fit for any work, as presumably they have "active" disease and still require institutional or hospital treatment. Sanatoria are maintained mostly by State and rate finance, and are usually the centre of the active anti-tuberculosis work in their district, with their patients living somewhere reasonably near.

The Graded Factory.

I would suggest that in an area where a sanatorium has been deemed necessary a "graded factory" should be erected. From a census of the occupations followed by all types of patients on the tuberculosis roll in this area can be formed a very definite idea of the products to be expected from such a factory. All ex-tuberculosis patients are worth a certain percentage in the market; under favourable circumstances every patient can raise his percentage value, as he can on graded work in a sanatorium, after the system laid down by Marcus Paterson. I consider it injurious and unnecessary in the majority of cases that a patient undergoing treatment should give up his occupation and, as usually happens nowadays, be taught a new trade. It is impossible to expect a man of, say, 40 to keep himself let alone a family also. Exceptionally few occupations per se cause tuberculosis: it is always the circumstances which are adverse and cause all the trouble. In my scheme, therefore, an ex-patient would continue his occupation in this factory according to his grade capacity.

The factory, its machinery, shops, and grounds would, of necessity, have to be as hygienic as the dwellings in a colony or sanatorium. As regards percentage of normal work, say an ex-patient bricklayer can do a grade of work worth 40 per cent. of the normal amount. There may be other ex-patient bricklayers, some at 30 per cent., some at 90 per cent.; the percentages can be worked in with one another, so that a 100 per cent. time sheet, and in effect a 100 per cent. value sheet is finally obtained in bricklayers' work in that factory.

It must be fully realised that working under favourable conditions an ex-patient may be worth and able to perform the real 100 per cent., in which case he would receive full market wages. The sole charity which this man accepts is the fact that he is recognised by the community as a "lame dog" in the open market only. His incentive to work is that of a normal man—wage-earning and all that appertains thereto—and he works the better knowing that health is for him the only way to economic independence. The 40 per cent. man can, at least, raise his standard of health and his economic value. In my scheme, while his value is low, he receives material charity to the extent of the difference, in this case 60 per cent.; what is not found for him is the means to escape this 60 per cent. charity and dependence, and to earn his 40 per cent. It is this difference which exists between any present-day scheme in care and after-care treatment and the proposal which I am putting forward, and which I desire to stress. An ex-patient, in my scheme, on entering a graded factory is made a useful and self-supporting member of the community, and set on the road to self-reliance, hope, and independence.

Staffing and Supervision.

In charge of this factory would be (1) a business manager, and (2) a physician well versed in the theory and practice of auto-inoculation—the combination working like a captain and his medical officer in a ship. The ex-patient should be graded by the medical officer, and the manager should set him to work in the correct grade, his time and pay-sheet being allotted accordingly. The manager would make up the quota of work in the factory by interlocking the various percentages. The medical officer would adjudicate the grades by temperature chart and periodical examinations. I would propose that each patient should keep a chart and record his own morning and evening temperature, and that on arrival at and departure from the factory his temperature should also be recorded. Fortnightly or at longer intervals his grade should be raised. If an auto-inoculation or breakdown occur the ex-patient would become an in-patient in his former institution or at home, and, as at present, receive sickness benefit—only instead of having a precarious inducement to leave the institution he would have a very real one—re-admission into the graded factory.

An important point in the scheme is that this factory is central, and therefore work-travel, a serious obstacle in the life of many ex-tuberculosis patients, is practically eliminated. It seems to be the modern tendency of good manufactory houses to have sufficient space around their factory for the recreation of their employees and for the employees to reside in the neighbourhood of parks. Thus an ex-patient also will have a home life and a working life, whatever his occupation, like an ordinary citizen.

By what means can this graded factory be raised and maintained? How have various colonies and sanatoria throughout the country been established? Cannot they one and all come from the same source? Some sanatoria are self-supporting and even make a profit. I do not know any colony that does.

Economic Aspect.

Once established, I consider that this graded factory could be run on a sound economic basis, the products would be on the open market at current prices, and the community would know that there was no exploitation of labour, but would realise, as in institutions for the blind, each ex-patient workman was giving his full percentage worth. The more the ex-patient flourished as a workman, the less would be the calls on charity. Such a scheme embodies a definite and workable plan of management. A graded factory can be maintained by any governing body such as controls our sanatoria, and attains the object of all schemes for care and after-care treatment in tuberculosis—viz., the assurance of work and wages for men, women, and children alike, and the opportunity of maintaining self-respect, self-reliance, and independence. The work of the tuberculosis dispensary would still be of the utmost importance as a clearing house for discharged sanatorium patients. The tuberculosis officer might draft the patient with his sanatorium grade into the graded factory, without loss of time, and the patient, spared the trials of unemployment, would thus be able to work at his own particular trade under sanatorium conditions.

It is obvious that the financial aspect of this scheme will have to be investigated with care by experts, but I am fully convinced that the expenses would not equal a tenth of those involved by a "colony." From the medical and public health point of view I feel assured that the graded factory would supplement the valuable work in the prevention and treatment of tuberculosis done by the sanatoria, the result of which is at present often lost. The ex-patient and his family will gain new hope, and therefore a renewed interest in life.

Note.—I am interested to read in Dr. A. S. MacNalty's article "Tuberculosis Work in England," in THE LANCET, Jan. 26th, a suggestion that there is or will be in Leeds a scheme in care and after-care treatment on some such lines as I have proposed.

PUBLIC HEALTH IN THE CAMEROONS.*

ACCORDING to a report bearing the signature of Lieut.-Colonel H. C. Moorhouse, Lieut.-Governor of the Southern Provinces of Nigeria, based mainly on material supplied by the resident (Major F. H. Ruxton), the Cameroons Province is at present divided into four medical areas, which correspond roughly with the natural features of the country: (1) The sea coast of Victoria and the plantations in the neighbourhood; (2) the hill station of Buea with Kumba; (3) the river plain of the Cross River (Mamfe Division); and (4) the table land area of Bamenda. Medical officers are stationed when available at Bamenda, Mamfe, Buea, and Victoria, with a native dispenser at each station. Each of these areas has its localised diseases and sanitary problems. These are but slightly affected by the ex-German hospital and sanitary arrangements, as the areas which have to be served by the stations are very extensive and the people not advanced in questions of public health. The natural advantages of the country in being for the most part of a mountainous nature with a relatively low temperature and good natural drainage and water-supply counteract many of the evils which would otherwise flourish. In the forest area the soil is mainly clay and natural drainage poor; there is no attempt among the natives to instal any system of soil disposal other than shallow pits scratched in the jungle close to the village, and with no regard to the source of drinking water, which is generally the nearest stream. It is understood that the "street-system" of villages throughout this area was the invention of the Germans for political reasons. A description of a typical village may be of service: A wide road, beaten flat by constant traffic, along which the town extends on either side with as few breaks as possible, to avoid separate walls and roofs in construction of the houses; the length of this street is limited only by the number of inhabitants, and forms a tunnel along which ventilation is only possible in the line of the street; the houses, low and dark, built flimsily of wattle and daub, with poorly thatched roofs,

* The German Protectorate of Kamerun on the west coast of Africa between British Nigeria and French Congo was obtained by conquest by Franco-British forces during the war of 1914–18, and at the conclusion of peace its administration was confided by the Supreme Council of the Allied Powers to Britain and France jointly. The British sphere is a wedge-shaped strip, running with the Nigerian border, and containing an area of about 28,000 square miles. It is administered by the Nigerian Government.

lighted and ventilated as a rule only by a low door at front and back; no shade along the road, which may run for three miles through a village of this type; no trenching in front of or behind the houses and clearing of bush behind, so that all refuse and night soil is deposited a few yards from the dwelling. Cultivation, is as a rule, some distance from the village, so that the latter does not obtain the benefit of cleared and clean ground around it. Throughout the area a common source of income appears to be pig-breeding, these animals being neither fed nor penned, and drawing their food from jungle weeds and village garbage, with free access to either. The staple food of the people is the bulb of the "coco-yam" arum lily, which is a bulky and perishable article of small nutritive value. It is, however, fairly easy of cultivation, though there appear to be large areas where the true yam as well as maize could be grown. Around the food question revolves the vital and vicious circle of infant mortality. This depends on the well-being of the expectant mother, whose status appears to be low in the Cameroons, where all the manual labour of the farm and the house falls to her share. The people themselves are most anxious to seek treatment for their children, who come to the local dispensary in large numbers for medicine, and every case serves as a text for impressing the value of simple measures in feeding and cleanliness, which the parents appreciate. On the other hand, the great majority of the people appear to be chronically underfed and the women overworked while young and neglected when old. The staple diet is inadequate for young children and the sick, who fall an easy prey to such complaints as ulcer, skin diseases, and intestinal parasites. In Bamenda the country possesses great assets in being well drained, with a temperate climate, and in possessing good food supplies. Large quantities of potatoes, introduced by the Germans, are grown by the natives for their own consumption. The water-supply is abundant, and fairly free from contamination, being from mountain streams. The general type of native is sturdy and markedly free from the chronic ailments that are seen in the forest area drained by the Cross River. The system of plantations around Victoria has hitherto employed large numbers of natives (11,000 in August, 1922). These men and boys receive free medical treatment in hospitals, of which there is one on every plantation, with native dressers and attendants under the supervision of the medical officer. There have been no widespread epidemics, and there is a remarkable absence of diseases attributable to the nature of the work. Serious cases can be transferred to hospitals at Buea or Victoria directly under the supervision of the medical officer. Throughout the Cameroons the people have willingly submitted to vaccination and to medical instructions regarding isolation and treatment of infectious cases. Acute cases of bronchial pneumonia occur at the "change of season" from the dry to the wet, and vice versa; the natives attribute this to the effect of the influenza epidemic of 1918. It is probable that the infection of that epidemic will linger for some time, especially in the areas of overcrowding and heaviest rainfall. It is hoped to establish small dressing stations, of the nature of "aid posts," under the direction of the medical officers and staffed by natives sufficiently trained to use simple remedies, who will advise the local inhabitants in sanitary measures. With improved communications it will assuredly be found that not only will the people be able to seek medical advice more freely, but that the freer exchange of commodities will raise the standard of living and increase the food-supply, with the improvement of the health of children. The fact that the birth-rate is low does not appear to be due to venereal disease, few cases of which are seen except in the stations, where they appear to be imported, and do not go with a system of professional prostitution. Promiscuous relations seem generally due to the inability of the man to pay the dower asked for a girl, who may therefore decide to live with her "friend" for a period, depending on his whim or means. As such union gives her no claim on the children, the discarded woman has to find another refuge, having no independent means. The practice of holding the children of a marriage in bond to the woman's parent until the whole dower is paid has also an adverse effect on the increase of families, and as the man in a position to afford several wives is usually elderly there are few children in proportion born to him, with the added disadvantage that the offspring of the young and healthy women of a village may be nearly related by blood. Throughout the Cameroons the natives avail themselves willingly of medical advice and treatment, and appreciate the superiority of European methods to their own, though, as elsewhere, they often delay coming to hospital until their own methods have proved unavailing, and are disappointed that the white man's cure is not more swift and spectacular. For this reason the majority of patients who are willing to undergo prolonged treatment in Government hospitals are surgical rather than medical cases.

FOOD POISONING AMONG ANIMALS.

DOMESTIC animals seem less able to discriminate between good and harmful diet than do wild animals. When the farmyard stock is out at pasture, and particularly in the spring after the long winter months of dry fodder, the succulent green of the meadows overcomes old instincts, and poisonous vegetation is consumed undetected. In this way, such toxic substances as ragwort, horse-tail, yew, laurel, and laburnum are often eaten. Poisoning among animals is dealt with at length in the January and February issues of *Veterinary Journal*. The ingestion of poisons may be accidental, through ignorant administration of dangerous drugs, or through the animal consuming some so-called harmless rat-poison. Poison may be present as an adulterant of certain prepared foodstuffs, or may be due to vegetable, animal, or mineral contamination of the drinking water.

Many sick animals are treated by their owners with overdoses of potent medicaments or with quack preparations of a harmful nature, and G. W. Clough, D.Sc., of the Royal Veterinary College, London, cites some interesting cases of fatalities in sheep, goats, pigs, and dogs from the use of proprietary medicines which contained poisonous drugs in over large proportions. As examples of food adulterants which not infrequently cause death, mention is made of excessive amounts of salt in fresh meat, castor beans in cake, and barium carbonate in sharps. In parts of the country situated near lead-mining districts deaths frequently occur in horses, cattle, sheep, dogs, cats, and poultry from lead poisoning, and many accounts of cases and the post-mortem symptoms are given. The streams that run away from lead mines over the surrounding country are especially dangerous for watering stock. Malicious poisoning forms another category. Students of toxicology will find much that is interesting and instructive in these two issues of *Veterinary Journal*. The cases of poisoning that veterinary surgeons meet with are numerous and varied, and the experiences recorded are worth reading by those who take more than a passing interest in the subject.

THE HYGIENE OF THE COMMUNION CUP.

WE have received a pamphlet bearing the above title, written by Dr. W. H. Read, and published in Sydney by the *Christian World*. The pamphlet deals with two questions: Is there danger of infection from the use of a common cup at the administration of the Holy Communion? and Should each several communicant have his own private cup? We have dealt with these problems from the medical point of view upon several previous occasions [1] and we can but repeat our opinion. The use of the common cup may transmit disease, although the risk is but slight except in places where a number of obviously tuberculous communicants are present. The only methods of avoiding such risk are: (1) the communicating the laity in only one kind; (2) the use of the form of communication known as intinction; and (3) the use of individual cups. Of these three methods (1) is allowed by the Roman Church, which employs it, to be contrary to primitive practice; (2) is objected to by one school of thought as being contrary to the command "Drink ye all of this"; and (3) is objectionable to our mind on account of the difficulty of providing for the proper cleansing of the cups. Despite the opinion of the Rev. F. W. Reeve, who writes on p. 28 of the pamphlet that "the only objections met with are from extreme ritualists, who would be unable to perform certain oblations (sic) quite unauthorised by the Prayer-book," we can assure him that the question of proper cleansing (for we imagine that the reverend gentleman means "ablutions" when he writes of "oblations") is a serious matter to many others than extreme ritualists. Intinction therefore seems to us the best way out of the difficulty. It is primitive, it is decent, and reverent, and we would commend to the notice of those who object that the method minimises the command "drink" the following point, namely, that the two Evangelists, St. Matthew and St. Mark, in their account of the crucifixion, when describing the giving of the sponge dipped in sour wine to Christ on the cross, both use the word ἐπότιζεν—i.e., "gave him to drink."

THE TEMPERANCE REFORMER'S HANDBOOK.

IN the Alliance Year Book and Temperance Reformer's Handbook for 1924 (London: U.K. Alliance and Headley Brothers, pp. 269, 2*s*.), many aspects of the problem of alcohol are considered from the point of view of those who, in their own words, "were satisfied that the history and results of past dealing with the liquor traffic in all lands had abundantly proved that it was impossible satisfactorily to limit or regulate a system so *essentially mischievous*." A foreword contains a brief account of the United Kingdom Alliance and of its activities—which, as is well known, are political rather than religious—from the foundation of the organisation in 1853 to the present day. Messrs. B. S.

[1] THE LANCET, 1900, ii., 1088 and 1364; 1903, i., 1186; and 909, i., 1698.

Spence and H. A. Job contribute articles on the temperance position in Canada and Australasia respectively. Sir Auckland Geddes's memorandum on American Prohibition is very interesting, not least because he has tabulated side by side the statistical conclusions relating to the effect of the Volstead Act (passed in October, 1919) from three sources: (1) the Anti-Saloon League, (2) the Association against the Prohibition Amendment, and (3) the Federal Prohibition Unit of the United States Treasury. The enormous discrepancies in these comparative figures explain the confused echoes which arise in this connexion on our side of the Atlantic. Thus the number of arrests for drunkenness on a 100 per cent. basis of the number in a given time during the period before prohibition is put at 50 by the League, at "fully 100" by the Association, and at 50 by the Treasury Unit. The figures of deaths from alcoholism, similarly compared, are given as 20, 250, and 20 per cent. respectively; and other supposedly carefully-compiled statistics show similar differences. Sir Auckland Geddes also notes that since the adoption of prohibition a large increase—computed at 40 per cent.—has taken place in the amount of deposits in savings banks; the claim that prohibition has increased production in the factories and has bettered the home conditions of the average wage-earner is, perhaps, rather lightly dismissed, with the comment that "so many other factors have contributed to restore economic conditions in the United States since the war that it is almost impossible to form any estimate of the extent to which prohibition has contributed to this recovery, or otherwise." In an article apparently reprinted from the New York *Outlook*, Mr. Raymond Spears writes of "The Furtiveness of Liquor," and makes the following statement: "I can walk the streets of my town and not see ten drunks in six months, when in half an hour before prohibition came I saw and counted thirty-odd in 15 minutes. And, with my eyes open, I drive tens of thousands of miles and see no drunken men, and the pitiful dejection or recklessness that is the mark of illicit liquor on property and community and individual appears only at long intervals, and one must know it to recognise the sign." Another interesting feature of the Year Book is a series of "pictorial studies in temperance economics," or posters issued by the Alliance in leaflet form for propaganda purposes. The full text of the Intoxicating Liquor (Sale to Persons under Eighteen) Act, 1923, is also included. The usual full index facilitates reference.

A USEFUL HYPODERMIC OUTFIT.

Dr. John W. Tomb, medical officer of health, Asansol Mines Board of Health, Bengal, sends us the following description of a useful and compact hypodermic outfit which he has used in India for over ten years under all conditions of transport. He writes: "The universal use of hypodermic medication necessitates the possession of an outfit which will secure the minimum waste of time in its employment with the maximum of surgical sterility. The hypodermic outfits sold by the large manufacturing houses are costly and require very considerable care in transport. I claim for the outfit here described that it is cheap and always ready for use. It consists primarily of a three-piece 60-minim B. & W.'s all glass hypodermic syringe, with a platino-iridium needle, size No. 27. The syringe when originally assembled is sterilised by boiling in its metal case and is *never afterwards taken apart*. The platino-iridium needle is also originally sterilised by boiling but on all subsequent occasions is sterilised by heating in the flame immediately before and after use. As an additional security against contamination, and to preserve the point against injury, the needle is kept in an empty sterilised hypodermic tabloid glass phial of suitable size with the point of the needle directed upwards and embedded in the cork, a pledget of sterilised cotton-wool being placed at the bottom of the phial. The "lamp" consists of an ordinary 2 oz. glass-stoppered narrow-necked bottle filled with methylated spirit and provided with a separate (locally made) brass or other "burner" with a wick of twisted cotton strands. To wash out the syringe after use and at the same time to sterilise it and to maintain it constantly in sterilised condition, and also to prevent the glass piston from sticking to the barrel, a mixture of equal parts of glycerine, carbolic acid, and rectified spirit is provided in a ½ oz. glass-stoppered bottle. The needle having been previously sterilised in the flame, five to six minims of this mixture are drawn into the barrel of the syringe on each occasion after use. The piston is then gradually withdrawn while holding the nozzle of the syringe upwards, so as to allow the mixture to escape and at the same time thoroughly to wash it out and lubricate the whole barrel, the piston being subsequently replaced. A small teaspoon is included in the outfit in which to dissolve the hypodermic tablets by boiling, and thus secure that none but sterilised solutions shall at any time be taken into the barrel of the syringe. In the tropics it is often desirable to assist the cooling of the sterilised hypodermic solutions by immersing the tea-spoon to half its depth in a little cold water in a saucer or other suitable vessel. Not more than 60 seconds are required for this operation.

The whole outfit is contained in a stout cardboard box 7½" long by 4" broad by 2½" deep, with a cover of the same material. The box is half filled with cotton-wool to absorb shocks and to protect the contents from injury. As an additional protection a layer of corrugated cardboard is also fitted around the inside of the box on all sides, and a the top."

THE GLASGOW ROYAL INFIRMARY.

AT the annual general Court of Contributors of the Glasgow Royal Infirmary, held on Feb. 11th, the report by the managers for 1923 was submitted. The work of the infirmary has increased considerably during the past year. Beginning the year with 653 in-patients, the total treated in the wards during the 12 months numbered 12,759, being an increase of 1397 on the previous year. There were on occasion no fewer than 789 patients in the house at one time, the daily average number resident being 722·9, and the average period of residence 20·7 days. In view of the large numbers waiting admission, some overcrowding was unavoidable. The number remaining on Dec. 31st was 672. Similarly an increased volume of work was carried on in the out-patient department, where 48,693 patients, being 4004 in excess of the number in 1922, attended for advice and treatment, while the total number of attendances was 220,193, as compared with 188,532. At the ophthalmic institution 855 in-patients and 13,541 out-patients were treated. At the Schaw Home, Bearsden, 1041 persons were received as convalescent patients. One outstanding feature has been the introduction to the infirmary of the treatment of diabetes by insulin. Since February last diabetes has been treated with insulin at the infirmary with satisfactory results, but the investigations are not complete, and are being continued. The Royal Infirmary has not a bio-chemical laboratory, and special arrangements were made to supply the need, but with the help of some friends the necessary funds were raised so that the infirmary funds were not called upon to defray any of the expenses of this investigation. As soon, however, as the experimental stage was past, the managers decided that the cost of insulin should be borne by the infirmary. The managers apprehend that another addition to expenses must soon be made by establishing a bio-chemical department, to aid not only in the actual treatment of the patients, but also in the investigation of those diseases which are due to faulty metabolism. In view of the widespread stagnation of trade and increased difficulties due to unemployment and other causes, it is matter for congratulation, the report states, that the financial year terminated satisfactorily. The total amount received from all sources exceeded the sum for the previous year. On the other hand, expenditure rather increased. To equip the infirmary adequately to meet modern demands and developments in all departments of medicine and surgery, a large fresh expenditure will also be necessary. Subscriptions from employees and others were generous, though slightly less than in the previous year. The widening of the scheme for organised weekly contributions in works, warehouses, &c., continues to bring in new and increased subscriptions. The ordinary expenditure of £107,686 was £2873 more than in the previous year, and the ordinary revenue amounted to the sum of £82,976—a deficiency of £24,710. There were received during the year the sums of £21,224 in legacies, and £11,200 by way of donations. These sums were drawn upon for extraordinary expenditure of £1301 and to meet the above deficiency of £24,710 on ordinary revenue account. In the final result there is a surplus of £6113.

One Who Believes, &c.—A letter has been received on the subject of an Osteopathic Directory, which can only be inserted if the author entrusts us with his or her name and address.

Lettsomian Lectures

[ABRIDGED]

ON THE

TREATMENT OF PULMONARY TUBERCULOSIS.

Delivered before the Medical Society of London

BY R. A. YOUNG, C.B.E., M.D., B.Sc., F.R.C.P. LOND.,

PHYSICIAN TO THE MIDDLESEX AND BROMPTON HOSPITALS.

LECTURE I.

(*Delivered on Feb. 18th.*)

THE scourge of tuberculosis has probably been coeval with civilisation, if indeed it does not date from the time when man became gregarious or from that period when he first made an enclosed habitation for himself. In this connexion it is of interest to note that although tuberculosis occurs in many mammals and in some birds, it is rare, if not unknown, in their wild state, and only becomes apparent when they live in association with man, or under conditions of confinement in stalls and zoological gardens. Anthropoids do not contract it in the wild condition, but are extremely susceptible in captivity. These facts are significant in connexion with the incidence of the human disease. Oxen, pigs, the dog, and to a less extent the cat, suffer from this disease, while the horse, sheep, and goat are more refractory. At the same time most mammals are susceptible to inoculation, and even the most refractory seem only to have the power to inhibit the activity of the bacillus, not to destroy it.

The form of acid-fast bacillus occurring in fish, amphibians, and batrachians is probably an entirely different organism. It is only of interest in regard to that from the attempt made by Friedman to utilise it in the treatment of the human disease. The problem of the rôle of the bovine bacillus in producing pathogenic effects in human beings need not be considered at length in regard to the subject I have chosen, since only in children does it seem to have any real incidence, and then its stress falls upon the glands, bones, joints, peritoneum, and meninges. In pulmonary tuberculosis, as seen in the adult and the adolescent, the bacillus found is almost without exception of the human type. At the same time this question raises a pathological point of great importance which may well prove to have practical bearings in regard to treatment. This is the relationship of early bovine infection which is recovered from, to human infection later in life. There is much evidence to support the view that early bovine infection serves as a protection to later infection, except when this occurs in massive doses or under unfavourable conditions.

[The lecturer then dealt with the history of the treatment of tuberculosis from the earliest times to the present day.]

NATURE OF PULMONARY TUBERCULOSIS.

The discovery of the exciting cause of a disease is generally hailed as the harbinger of its cure, and as giving hope of securing its prevention and eradication. The history of the treatment of tuberculous disease since the discovery of the tubercle bacillus by Robert Koch in 1882 shows that such hopes may be vain, and that for effective treatment the fullest knowledge of the causative agent and of its effects may be necessary.

The list of treatments recommended for tuberculosis is an ever-lengthening one. This alone affords little encouragement, for we can, as a rule, judge the efficacy of treatment as inversely proportional to the number of remedies suggested. In this disease there is certainly no lack. They vary from absolute rest to the most strenuous exercise, from life at sea-level to high altitudes and even to balloon ascents, from hyper-alimentation to grape cures, from serum therapy to vaccines of various kinds, from inhalations to intratracheal injections, from silence to singing lessons, and from castration to thoracoplasty. We should aim at being eclectic, and thus securing for each patient that combination of management, locality, and medicinal agents likely to put him in the best condition to secure arrest and to restore him to health and working capacity.

From the prodigious literature relating to this disease, and from the welter of controversy concerning its pathology and treatment, certain generalisations emerge with almost the authority of axioms. These I may here state categorically, with a view to determining whether they afford any rational basis on which we may found our treatment, and whether there is any hope of a specific curative treatment in the future.

(1) Pulmonary tuberculosis is almost exclusively due to the human type of the tubercle bacillus.

(2) It is a disease sui generis and confined to man in its ordinary chronic form. Experimental infections of animals do not reproduce it.

(3) It is practically unknown in infancy, rare in early childhood, and becomes increasingly evident at puberty and in adult life.

(4) Under urban conditions in most countries exposure to infection by the tubercle bacillus is almost universal, either from bovine sources in milk and its derivatives, cream, butter and cheese, or from human sources by sputum or other discharges.

(5) Ninety per cent. of adults give some form or other of tuberculin reaction when tested.

(6) We must not regard the presence of tubercle bacilli within the body as evidence of tuberculous disease, and still less the occurrence of tuberculin reactions. The latter only indicate tuberculin sensitiveness due to previous tuberculinisation, either from bacilli spontaneously acquired or from previous administration of tuberculin.

(7) The converse of this is true—namely, that active progressive lung disease is consistent with a high degree of immunity to subcutaneous injection of tuberculin. This fact has been applied by dealers in the sale of pedigree cattle, and is now made a plea for the official control of the sale of tuberculin.[1]

(8) The development of pulmonary tuberculosis in a given individual indicates that the protective processes are defective, or that the infection has been gross or massive so as to swamp these processes.

(9) These protective processes vary in effectiveness in different individuals and in different races, and are never absolute.

(10) The tubercle bacillus is a very resistant organism in vivo, possibly in virtue of its lipoid rich envelope, and even the animals most refractory to its effects can usually only inhibit or prevent its activities without destroying it.

(11) In resistant individuals, both human and animal, the bacillus may live for long periods enclosed and apparently harmless while yet retaining its infectivity.

(12) In civilised races long exposed to its activities many infected persons recover spontaneously with very few symptoms, and even in ordinary chronic cases the course is often marked by periods of quiescence or regression, whereas in races not previously exposed its incidence is severe, usually acute, and rapidly fatal.

(13) Cases of pulmonary tuberculosis following on multiple tuberculous lesions elsewhere usually run a favourable course (Marfan's law).

(14) Koch's phenomenon, as briefly stated by Calmette, "Every already tuberculous body tends to expel a new dose of bacilli inoculated subcutaneously."

The explanation of these fundamental generalisations is difficult. We are each of us so inclined to interpret them in the light of our own special views as to the factors of infection, heredity, diathesis, immunity reactions, or environment. Koch's phenomenon, which I have just quoted, seems to offer the most probable explanation of the pathogenesis of pulmonary tuberculosis as it occurs in the adult. It is of interest to note that Koch himself, although he recognised the importance of his own observation, which indeed led him to the discovery of tuberculin, yet did not realise its significance in regard to the peculiar features of pulmonary tuberculosis in the adolescent and adult. Behring was the first to suggest that the primary infection in tuberculous diseases

[1] THE LANCET, Feb. 2nd, 1924, p. 247.

occurs in infancy or early childhood, and that the development of pulmonary tuberculosis might be due to the liberation of tubercle bacilli long enclosed by protective and reparative processes, owing to some local breakdown or diminished general resistance. He crystallised his views in the now famous epigram, "Phthisis is but the last verse of the song, the first verse of which was sung to the infant in its cradle."

Behring's views have been extended by Hamburger, who compares tuberculosis with syphilis, and maintains that it is as difficult to reinfect in one as in the other. The primary lesion is the local infection of infancy, the secondary stage comprises the glandular, osseous, articular, and serous localisations, while pulmonary tuberculosis and the other visceral forms are comparable to the tertiary and quaternary forms of syphilis. Römer, Krause, and others explain the genesis of pulmonary tuberculosis more strictly in terms of Koch's phenomenon. From this point of view pulmonary tuberculosis is the result of re-infection or super-infection in a patient sensitised or rendered "allergic" by a previous infection in infancy or childhood. If we accept this conclusion, we can explain many of the peculiar features of the disease, especially why it is a grave disease tending to the miliary type in infancy and in individuals of races not previously exposed. It also becomes intelligible why the mortality from the pulmonary form of this disease increases after 14 or 15, while that from the non-pulmonary form diminishes or remains constant.

It would seem probable that in infancy the disease is spread in the body by the blood, whereas in later life extension occurs by lymphatic channels, direct extension, or by inhalation, and only in miliary forms by the blood-stream. What still remains unsettled is whether the re-infection or super-infection takes place from breakdown of the old lesions of childhood or from bacilli introduced anew from without. Behring and Hamburger would seem to suggest the former, in which case infection is really only of importance in early life. On the other hand, the fact that pulmonary tuberculosis is exclusively due to the human type of tubercle bacillus, whereas admittedly a considerable proportion of tuberculosis in early life is bovine, would seem to suggest strongly the possibility of exogenous re-infection or super-infection, at any rate in some cases, and that the changes in the lungs are comparable to the changes described as resulting from secondary inoculation in Koch's phenomenon.

Recently Sir Almroth Wright[2] has published suggestive observations which show that in the patient suffering from tuberculosis with febrile reactions (or auto-inoculations if we accept this view) there is a greatly increased hæmo-bactericidal power compared with the normal, and this observation may well prove to be of great importance in suggesting treatment, by directing attention to the rôle of the leucocytes rather than of the serum and tissue fluids.

VARIATIONS IN TYPE.

Pulmonary tuberculosis is clinically a pleomorphic disease. It varies from a rapidly fatal condition lasting days or weeks at most, to a condition tending to spontaneous arrest, and giving rise to few or no symptoms, with cases of intermediate character in which its course is undulatory, and may last throughout a fairly long life.

It is customary to divide tuberculosis into types, and the most useful classification is into (1) acute miliary; (2) acute caseous—(*a*) broncho-pneumonic form, (*b*) lobar pneumonic form; (3) chronic fibro-caseous; and (4) fibroid. We may correlate these different types with variations in infective dose, heredity, susceptibility, the immunity responses or environment according to our personal views, but it is important for us to recognise as soon as possible to which type our patient belongs, for upon this recognition our prognosis and our treatment must largely depend. At the same time we must remem that these types are not hard and fast, that t disease is one in which it is difficult to forecast, a that in all types except the acute miliary, drama changes may occur either spontaneously or as result of treatment.

One of the most acute of the wise aphorisms of late Dr. Samuel Gee was, "Never give a defin opinion as to how long a patient suffering fr phthisis will live; for the only certainty is, that you do, you will be wrong."

The great problem of treatment in pulmon tuberculosis is that relative to the ordinary chro fibro-caseous type. It is customary to divide course of this form of the disease into stages, and this purpose the Turban-Gerhardt classification most generally employed.

PRINCIPLES OF TREATMENT.

At the outset I may state that I propose to c sider treatment of the individual patient suffer from this disease as the aspect of treatment m germane to the work of this society. I feel that collective character of the work being done un the ægis of the Ministry of Health to deal with disease from the sociological and public hea aspects may in some degree militate against interests of the individual patient, although the offi scheme is practical, helpful, and elastic. As pra tioners it is our duty to do the best for the patient w consults us. It is becoming increasingly diffic for us to do so. There is no disease in which diagn and treatment in the earliest stages is of more cru importance, yet the student gets less and less opp tunity of studying the symptoms and signs of t disease, as it comes more and more under the cont of the health authorities and appears less and in the out-patient department and wards of teaching hospitals. Again, the dispensary and sanatorium are the centres round which the offic diagnosis and treatment are pivoted, whereas it in the home and the hospital where the initial sta are best studied, and it is the general practitioner the great majority of cases who sees the cases in earliest and curable stage, and upon whom responsibility of early diagnosis rests. Notificat by him brings the case within the purview of tuberculosis authorities, and may be of great va as the means of securing treatment for those limited means.

The first principle of treatment should be to see the case as early as possible, and for this purpose is necessary to be on the watch for suspicious sy ptoms. Early suspicion in cases of obscure illnes the attitude of mind we must cultivate. To ena the practitioner in the future to do this it seems me that it may be necessary to affiliate more of tuberculosis dispensaries to the teaching hospit and to increase the opportunities for undergradu and post-graduate study of the disease in all stages. I feel also that a short stay as resid clinical assistant in a sanatorium might be a v valuable form of post-graduate study if it could arranged.

The second principle is to recognise the type a stage of the disease and to adapt treatment according

The third principle is to increase the resist power of the individual by every means in our pow The study of occupation, of environment, and of p sonal history becomes of the greatest importance. present, unfortunately, our chief means of increas immunity are indirect and non-specific.

The fourth principle is to secure as complete r as possible to the diseased lung or part of the l with a view to localising the effects of the dise and preventing systemic toxic reaction, or, in oth words, auto-inoculation. It may be a question even yet the importance of this factor in treatm is sufficiently recognised, except by those in da contact with the problems of tuberculosis, and it certainly not understood by the majority of patie and still less by their friends. The object is

[2] THE LANCET, Feb. 2nd, 1924, p. 218.

onvert the lesion from an open to a closed condition, om a spreading toxic process to a localised, non-oxic healing one.

DIAGNOSIS OF ACTIVE DISEASE.

It is obvious, therefore, that to determine what eatment it is best to recommend for a given case, e must first diagnose the presence of active tuber-ulosis, and then assess the type of the process, its calisation, and the degree of activity. It must be pparent that it is well-nigh impossible to do these ings in a single interview, no matter how exhaustive how careful the examination may be, and it is nportant that it should be generally realised that o make a diagnosis may involve careful observation or some days at home or in a nursing home. This is ow appreciated by the Ministry of Health, but is ot recognised by private patients.

It may, therefore, be of interest to inquire what nformation we should try to secure in order to make working diagnosis. We need a full and careful istory, as regards the family, the previous illnesses, nd, if possible, the habits, occupation, environment, nd even the personality of the patient. We should btain a detailed statement as to the symptoms, heir onset and progress. This is often difficult, but is well worth the labour and patience it often equires. Then the physical signs must be most arefully worked out, and great attention paid to mall variations from the normal which may often ave to be interpreted in terms of the symptoms. We should look specially for symptoms and signs of oxæmia. At the same time it must be emphasised hat extent of physical signs is no criterion of activity, nd may be a fallacious guide to prognosis. A record f temperature spread over several days and if pos-ible more than the usual morning and evening read-ngs, since the rise in this disease may occur at nusual times—e.g., late in the evening or early in the fternoon or even in the morning—is essential. With uch information as a minimum we may usually obtain tentative diagnosis with some probability as to ccuracy, but no certainty. We must therefore try o secure other evidence.

Sputum Examination.—The presence or absence of ubercle bacilli is too often taken as almost the sole riterion of diagnosis and of activity. This is incorrect n both directions, since some cases of undoubtedly ctive disease may be closed and not show tubercle acilli, while in some cases in which they are present here may be practically no symptoms and the patient nay be capable of an active life, if he realises his estrictions and his public duties.

X ray Examination.—This is a record of very great alue, which will doubtless become more generally sed even than at present. It should, however, be ept until after the information suggested above has een obtained, when its results can be correlated herewith and placed in the correct perspective. I egard X ray examination rather as a means of onfirming the presence of tuberculosis, of revealing ts extent and the presence of complications, than as a neans of diagnosis. It is also essential in deter-nining the application of some forms of treatment, specially that by artificial pneumothorax. It may lso afford valuable information as to the progress after reatment.

Apart from the means of diagnosis, what we most eed is some means of assessing activity in patients vith doubtful signs, and in those in whom the clinical eatures suggest arrest or obsolescence. Much pioneer ork has been done in this direction, but a reliable nethod is yet to seek. Other sputum tests such as he presence of albumin are not specific.

Tuberculin reactions, especially the subcutaneous nd the quantitative Pirquet, may give useful nformation, but the former is not devoid of risk and is napplicable in cases with fever, while the latter cannot e taken as a strict measure of activity.

Complement Fixation.—These tests are on trial, and mportant claims have been made by some observers. There is, however, at present too big a margin of error to allow of reliance being generally placed on the results.

Opsonic Determinations.—In my experience these may be of value in special hands, but they have practically been given up owing to technical difficulties.

The Wildbolz auto-urine test and its serum modification do not seem to justify the claims made for them.

It is familiar to all that even with all this information there may be an element of doubt in our appraisal of a closed case of tuberculosis or a difficult case with obscure signs. We have often to act on the balance of probability, and may take comfort from the fact that it is a less serious error to send a patient with some obscure condition causing ill-health to a health resort than it is to fail to recognise and treat an early case of pulmonary tuberculosis.

INDIVIDUAL TREATMENT.

In selecting treatment for a given case we must give due weight to family, financial, and personal considerations. It is wise always to consider carefully the patient's personal predilection, but never to be argued into a course which we feel to be unsuitable.

Treatment may be at home, in a nursing home or hospital, a sanatorium, at some mountain resort, or at some marine or other climatic station, and at various stages a case may be suitable for several of these in sequence.

Home Treatment.—In the febrile stage home treatment may be the most suitable—provided that conditions are favourable and that the practitioner in charge is familiar with the principles of treatment, and further, that the patient and those in attendance, whether relatives or nurses, carry out instructions literally. When toxic manifestations have abated and the fever has subsided, then removal to sanatorium or other place may be considered. It should be remembered that toxic symptoms may be present with little or no fever. Home treatment may also be best suited for chronic, slowly progressive cases in which other measures have failed, for cases complicated by visceral metastases or by other conditions, and also for advanced cases, if the risks are realised and due precautions are taken. That home treatment is possible throughout the disease even in large towns has been repeatedly proved. In America this form of treatment has been organised and developed to a greater extent than in this country, especially by S. A. Knopf in New York, and by Pratt in Boston. The latter has developed what is known as the "class method," which has also been used in Montreal. The methods employed are worth study, as much ingenuity has been shown in devising methods to secure as much open air as possible, and to give help and advice to patients. For the majority of cases, however, home treatment should only be used as a preliminary to treatment at a sanatorium or elsewhere. In this connexion it is well to utter a word of warning. Too often, while the patient is waiting to be received into a sanatorium, he works hard to clear up his affairs, and fails to regard himself as under treatment. Rules should be given to him as soon as the disease is diagnosed.

Nursing Home or Hospital.—For domestic or financial reasons, it may be impracticable to carry out the necessary preliminary treatment at home. In this case a period in a nursing home or hospital may solve the difficulty. Homes for advanced cases for all classes except the rich are a great need, as it may be very difficult to place a case who is not in any sense a candidate for one of the homes for the dying and yet requires institutional treatment.

Sanatorium Treatment.

There is no form of treatment about which so many misconceptions exist as that in sanatoria, not only on the part of the public, but even in the minds of some members of our own profession. I regard this form of treatment as of the greatest value, and I believe there is a stage in the majority of cases, other than the acute, when it may be the best form to adopt, not only for its educational value, but as a means of achieving arrest

in the shortest time. On the other hand, to regard sanatorium treatment as the standard treatment for every case and to send unsuitable cases is uneconomical, unkind, and useless. A sanatorium filled with unsuitable cases is not a sanatorium, but a country hospital for advanced cases, for which it is ill-equipped and unsuitable. Sanatorium statistics, of which there is almost a glut, seem to agree upon one point only—viz., that the best results are obtained in the so-called first-stage cases and in those without tubercle bacilli in the sputum. This serves to emphasise the importance of early diagnosis and of the selection of suitable cases for this treatment. Only in this way does sanatorium treatment become economically sound, whether for industrial cases or for the well-to-do.

It is a truism that the success of sanatorium treatment depends more upon the personality of the superintendent and upon the manner in which the institution is run than upon its situation. At the same time, success is dependent not only upon the right type of case being sent, but also upon the loyal coöperation of the patient. The practitioner sending a case may help materially by instructing the patient as to the rôle of sanatorium treatment, and endeavouring to prepare him for its restrictions.

The types of case suitable for sanatorium treatment comprise: (1) Early cases without fever; (2) early cases in which fever has subsided and the patient is able to be up at least four hours a day, and preferably six to eight hours; (3) old arrested cases with slight breakdown; (4) most cases in which artificial pneumothorax has been successfully established; (5) cases after pleural effusion. It should be remembered that it is not the duration of the disease or the extent of the lesions, but the degree of activity and of toxic reaction which have to be considered most.

Cases unsuitable for sanatorium treatment are: (1) Cases with active spreading disease showing fever and toxæmia; (2) cases with severe complications likely to require much nursing and prolonged stay in bed; (3) cases with chronic bronchitis, chronic arthritis, or with severe cardiac embarrassment; (4) tuberculosis in the elderly or aged. The conditions are apt to be too severe, and the restrictions unduly irksome; (5) certain patients of shy personality and home-loving character to whom removal to any institution is a matter of dread or dislike. Occasionally such patients settle down and do well, but as a rule they do better at home or under favourable conditions in country surroundings.

Character is a great factor in recovery. Sanatorium treatment fails sometimes in persons of not very robust personality, in whom we find marked deterioration of will and initiative. They become selfish valetudinarians, and wander from sanatorium to sanatorium, or remain for years at one, even after the disease is quiescent, thus becoming useless parasites on their relatives.

The question as to how long a patient should stay at a sanatorium is difficult to answer. It is often impossible for financial reasons for him to remain till arrest is complete, as this may mean a year or more, if set-backs from extension or from over auto-inoculation occur. In general, we may say that it should be at least four months, and, if possible, six or eight. Change to another sanatorium is often desirable when progress is slow. Change may also be of value in affording different surroundings, varied diet, and fresh amusements. Diet is a matter which should be very carefully studied in sanatoria, for there is a tendency in some to provide a definite weekly sequence of meals, which becomes monotonous and therefore unappetising.

Climatic Treatment.

A belief in the value of climatic change in this disease dates from Greek and Roman times. The proved value of the Swiss mountain resorts has appealed strongly to many people, and this form of treatment has been very popular in the past. The war period and the restrictive measures taken in various colonies, dependencies, and foreign countries to prevent the entry of tuberculous persons ha lessened the opportunities for this form of treatme and in any case it must of necessity be larg confined to the well-to-do.

Climatic resorts may be classified into mounta marine, inland, and desert. For this disease we m select places in which abundance of fresh air a sunshine are the rule, and where there is comparat freedom from dust and strong prevailing, ra bearing winds. Mountain climates have great adv tages in the pure rarefied air and the changes induces in the respiratory and circulatory syste also in the greater diathermancy of the air at th altitudes.

Mountain Resorts.—The Swiss resorts are th most convenient for patients in this country, and these there are many to choose from, at sufficien varied altitudes. Davos (5150 feet) has a lo reputation behind it, and accommodation to s patients of moderate means as well as the m affluent. Arosa (6000 feet) is now more eas accessible than formerly, and treatment here is w organised. St. Moritz (6090 feet) has developed n for other conditions than tuberculosis, and with arrangements for winter sports and for the healt is less to be recommended for the sick. Monta (5000 feet) has an unrivalled situation and a g record in sunshine. Leysin (4690 feet), the Mecca heliotherapy in surgical cases, has also accommo tion for pulmonary patients. For levels of ab 3000 feet there are Les Avants and other places the neighbourhood of Montreux. Other mount stations are those in the Rocky Mountains, such Colorado Springs and Denver, and those in t Adirondack Mountains, but these are not practica available for patients from this country.

Treatment at these mountain stations is chi suitable for patients out of health in whom diagnosis is doubtful, as they can receive treatm without the stigma too often attaching to patie who have been in a sanatorium, for patients w early afebrile disease or with localised disease a little fever, and for some chronic slowly progress cases, in whom ordinary treatment has failed secure arrest. It is important to recognise t there are many cases which should not be sent the mountains. Among these are advanced ca with active spreading lesions and toxæmia, ca with severe recurrent hæmoptysis from excavati or gross disease, or indeed any recent hæmopty cases with complications, particularly laryng involvement or enteritis, cases with extensive fibr disease and those with emphysema, cardio-vascu disease, or albuminuria. If good progress is ma the patients should stay till arrest is complete, a in many cases it may be wise to remain for a seco winter. Many patients leave for lower statio during the period of melting snow, though this not necessary and is sometimes risky. They sho not return to this country till May.

Marine Resorts.—It is usually believed that t actual sea coast is unsuitable for cases of this disea but the reason for this belief is obscure, and in a case it is said that the disadvantages disappear short distance inshore. The coast resorts in t country are very numerous. The French and Itali Riviera may be of use in cases of arrested disea but are less adapted for cases requiring active tre ment. Arcachon also is a convenient and suita winter resort for cases without much active disea Madeira, the Canaries, Morocco, and the No African coast may also be considered for cases quiescent disease, those with slight activity, a those with catarrhal conditions, but rarely for th with active signs. Sea voyages are now universa given up except for cases in which the disease arrested or quiescent.

Inland Resorts.—The moorlands in these islan especially those of Scotland, Yorkshire, and Dev afford ideal conditions for some cases, and go results are often obtained. Other suitable places

'alifornia, the high veldt of South Africa, and various places in Australia and New Zealand, but these are no onger possible to patients from this country.

Desert Stations.—The Egyptian deserts are sometimes advised, but are not ideal owing to the matter of dust. Practically the only places at all suitable are Helouan and Mena House, Ghizeh. Luxor and Assouan involve a long and tiring journey, and have a very short season.

General Management of the Case.

Having decided upon where treatment shall be carried out, it is necessary to determine and map out what that treatment shall be. The basis of treatment should be what Fishberg, to whose monumental work on this disease most workers in tuberculosis are deeply indebted, calls "the traditional therapeutic triad—air, food, and rest." At the outset it is wise to explain to the patient the reasons for the recommendations given. Patients are more likely to submit to the various restrictions and rules if they grasp that each one is given on reasoned grounds and not as a capricious or oracular pronouncement.

If treatment is to be commenced at home, the most suitable room should be selected, if possible one with a south or south-west aspect, and one from which the patient can easily be moved into the open when weather conditions permit. The furniture should be reduced to the minimum consistent with comfort, and arrangements made to reduce dust to a minimum, especially during the cleaning of the room. If the patient has to remain in bed for a prolonged period it is an advantage for him to spend the night in a different room or in a different bed. The windows should be widely opened, but direct draughts must be avoided, and in patients with catarrhal or bronchitic tendencies the room may be warmed to a suitable temperature. The rigours of the winter cold may be mitigated as far as is consistent with abundance of fresh air. The clothing on the bed may be varied as necessary, so that the patient is not cold and uncomfortable. The blue and chilblained extremities, so often seen, should be prevented if possible.

Outdoor shelters have a value, and should be introduced where possible, but there are times when the discomforts involved outweigh the advantages of the extra exposure to fresh air. When the patient is allowed up, the clothing should be warm and comfortable, but not excessive. Life in sanatoria soon leads the average patient to fear chill less as a cause of colds than infection. Flannel underwear is usually advisable, and loose comfortable warm clothes, with good boots, giving protection from wet and damp. If afebrile, the patient may have regular baths, cold or warm according to his custom, or if in bed with fever he may be sponged or blanket-bathed with as little disturbance as possible. In men with cough and sputum it is best to advise clean shaving.

Smoking.—Where there is much cough or active disease with fever, and in cases with laryngeal tuberculosis, it is best to avoid smoking. It may be permitted in moderation to cases where arrest is satisfactory, but inhaling should not be permitted.

Sputum.—It is of the greatest importance to instruct every patient, and those in charge of him, as to disposal of sputum, and the risks of indiscriminate cough. This is even yet not universally done. A difficult task is often that of explaining the great risks of infants or young children brought into contact with cases of open tuberculosis even for brief periods. It is desirable that this should be as widely known as possible, if the incidence of the disease is to be controlled. We want to make adults less anxious about their own risks, which are comparatively small, and much more concerned about those of the young, which are very great.

Diet.—The hyperalimentation of the early sanatorium days has given place to a more rational dietary. It is now recognised that gain in weight is not by itself curative. We should aim at improving general metabolism and restoring the patient to his "highest known weight." This having been achieved, the diet may be modified or cut down. A caloric value of from 3000 to 3500, according to the patient's build and amount of exercise, is usually ample, and only exceptionally in patients doing heavy work is it necessary to go beyond this. The increase may be made in protein up to a total of ¾ lb. of cooked meat a day, or part may be given as fish or eggs. Tuberculous patients usually tolerate fat well, and fat is generally regarded as of special value in this disease. It may be given in any palatable form. Milk is often given in large quantities at each meal, but when other food is being taken the amount should generally be less than two or three pints. Carbohydrates may be considerably increased where active muscular work is being done.

The diet should be as varied and as palatable and appetising as possible. Few patients go through their treatment without some degree of dyspepsia and anorexia, and it may require much care, patience, and ingenuity to secure an adequate and agreeable diet, particularly in patients confined to bed with fever. It is, however, remarkable how often patients with considerable rises of temperature retain their appetite, and can deal with more ordinary diets than patients febrile from other causes. Raw meat sandwiches have been recommended and may be tried. They can easily be made palatable, and may be taken with a little burgundy in the morning. Alcohol may be allowed in moderation to those accustomed to it, but as a rule it should be given up and milk or milk and soda-water taken instead. Various special diets, like the grape cure of Meran, sour milk, and the exclusive use of milk, have been recommended, but come under the category of freak or fad treatments.

Rest and Exercise.—It has been happily said that rest is the one treatment which has stood the test of time. Hilton's classical work has emphasised for all time the value of rest in the treatment of painful or diseased parts. In this disease complete rest is essential as long as there is fever and toxæmia, and, as we shall see, local rest to the diseased lung is a valuable means of treatment when it can be achieved. In febrile cases what is known as "absolute" or typhoid rest is usually necessary. The patient is kept completely recumbent and is waited on completely, not even being allowed to feed himself, or to get up to go to stool. This may be necessary only for a few days, or may require to be kept up for weeks or even months. It should be relaxed as soon as possible in order to encourage the patient. Rest, by lowering fever, lessening auto-intoxication, and localising the disease, is the most effective means of treatment we have yet evolved. The difficulty often is to persuade the patient that it is necessary and beneficial. He or his friends think it is weakening and are apt to attribute all his symptoms to it. It is here that sympathy and confidence between doctor and patient become of great value, and if we can convince him of its necessity a valuable step in treatment has been made.

Not only fever, but other indications of toxæmia and of auto-inoculation, such as headache, anorexia, dyspnœa, quick pulse, weakness, and depression may all render rest essential. Moreover, an excessive auto-inoculation from work or exercise, a local extension, or some intercurrent condition may render a return to bed necessary. It is usually stated that with a temperature of 99·5° or 100° the patient should be put to bed. This is true, but a more valuable indication is the general record of the temperature and pulse from day to day. An early morning rise or a quick pulse may indicate a fresh extension or an over-inoculation and necessitate return to bed. It is only when the temperature becomes steadily normal or subnormal that we can consider allowing the patient up, and gradually increase the time up and then permit exercise. The rate at which this may be done is one of the most difficult problems and requires judgment and experience.

THE PHYSICAL BASIS OF EMOTIONAL DISORDER.[1]

BY H. CRICHTON MILLER, M.A., M.D. EDIN. & PAVIA,
HON. DIRECTOR, TAVISTOCK CLINIC FOR FUNCTIONAL NERVE CASES.

IT has been claimed in the name of psycho-analysis that "every neurosis is caused by a psychic conflict." Without desiring to generalise on the pathogenesis of the neuroses, I propose in this paper to show how inadequate is such a conception. I submit that a theory of the neuroses based upon "the wish," or on the conflict between ego and social impulses is narrow to the point of being misleading, however valid it may be in a partial application. Further, I suggest that, apart from the Freudian theory, in actual practice psycho-analysts tend to seek in emotional experience the causation of all but a limited group of the neuroses. It appears to me that, however important the psychogenic factor may be, we must recognise that somatogenic factors are rarely absent, and that to approach the problem of the neuroses exclusively from the standpoint of psychic conflict is to compromise our therapeutic opportunity unjustifiably. Or, if we are determined to reduce our equation to terms of psychic conflict, let us frankly realise that one or other side of the conflict is frequently conditioned by factors of a biological nature, which are not beyond the reach of physical treatment. The neuropath brings life to a standstill, and the psychopath retreats from it, in each case because of his inability to orientate himself to the future. Is it not reasonable to suppose that much of this inability is based upon an awareness of organic inadequacy?

The value of the following formula should be considered as covering the ætiology of a large group of neuroses: Awareness of incapacity to meet a demand for adaptation present or impending. It will be convenient to discuss the subject under four headings: (1) Alimentary, (2) vascular, (3) endocrine, (4) sexual. These headings are not offered as a classification, as I am aware that they overlap at many points.

Consciousness of Alimentary Inadaptability.

It is clearly within the experience of each one of us that our emotional feeling tone is influenced by the minor physiological disequilibria of an empty stomach, a loaded colon, or a congested liver, and practical physicians are prepared to discount the emotional reactions associated with such states. But when a condition of this kind becomes chronic we may reasonably suppose that an equally chronic emotional distortion occurs which should preclude any thought of psychological treatment. Only a few months ago I saw a patient, X. M. M., who had undergone several months' treatment by an analyst for what he diagnosed as a mild anxiety neurosis. Being none the better, she consulted a surgeon, who removed a portion of her colon. She now claims to be well. I have no wish to express an opinion on the expediency of either form of treatment, still less do I wish to identify myself with the view either of the analyst or of the surgeon—both of which are known to me—but I am prepared to say that, if both lines of treatment were indicated the order in which they were carried out cannot be justified. I would go the length of surmising that the analyst must have spent a good deal of his time in attempting to resolve complexes which would have resolved themselves had the patient's feeling tone been more normal than is that of a typical case of chronic coprostasis. In other words, I believe that the psychic conflict which caused the anxiety neurosis was based on a general awareness of incapacity to meet the demands for adaptation which her daily life imposed on the patient. If I am correct, then the proper procedure would surely have been to eliminate first the factor of intestinal toxæmia which produced this sense of physical inadequacy.

Influence of Vascular Tone on the Emotions.

It is probable that few of us are sufficiently alive to the influence of blood pressure on emotions. The sensitiveness of the brain to high and low blood pressure, and to instability in blood pressure, whatever be its exact nature, is one of the factors most frequently responsible for emotional disorder. The patient with a consistent hypopiesis must inevitably experience a sense of mental, if not physical, inadequacy, and it may well be a matter of surprise to us when such a patient fails to show clear symptoms of emotional instability. There is a constant sense of inadequacy which may produce an anxiety state or else a constant craving for stimulating experience. Thus we have a considerable class of alcoholics whose craving for alcohol is fundamentally based on this sense of inadequacy due to a low cerebral blood pressure. Doubtless they all have their conflicts, which are bound to be exaggerated by the physical condition, but to say, as the psycho-analysts have said, that "All alcoholism is due to homosexuality," is gross misrepresentation which can only lead to therapeutic puerilities. On the other hand, there is a school of thought which deals largely in exhaustion neuroses and psychoses. The term seems to me a very unfortunate one unless it connotes curability by rest alone. Many of these cases are blood-pressure problems, and mere rest is neither a certain nor permanent cure for disorders of cerebral vascularity. Again, the mere fact of vascular instability has its emotional implications. The man of 60 whose arteries are beginning to harden finds that at certain times of the day his concentration fails him or uncontrollable somnolence comes over him. Surely we are justified in regarding this as a cause for deep concern on the patient's part—the sense of his failing capacity to meet the demands for mental activity which his business involves?

The Endocrine System and the Psyche.

It is impossible for us in the present state of our knowledge to have any exact conception of the influence of the internal secretions on the emotional life. But in regard to the thyroid, at any rate, we have some definite knowledge.

D. H. E., a woman of 32, consulted me for breathlessness, lassitude, and generalised fear. She had a pulse-rate of 120, slight exophthalmos, and a greatly enlarged thyroid. I sent her to a surgeon, who expressed unwillingness to attempt surgical interference. The patient was therefore ordered rest, and a colleague of mine undertook her analytic treatment. A mass of repressions was revealed. She had a profound father complex and a recent history of active homosexuality. She made some progress, but when she began to go about again her symptoms returned. The surgeon then consented to operate and extirpated a considerable portion of the gland. She made a good recovery, went to work, and has been fit for her work ever since, as far as I am aware.

Now in this case I am open to conviction that the psychic conflict was the sole cause of the hyperthyroidism, though I suspect that an element of bacterial infection must at one time have been operative. Let us, however, grant that the condition was primarily psychogenic. It remains undeniable that the physiological implications of the emotional conflict had reached a point at which no redress of the emotional equilibrium could effect a remedy. In short, emotion had affected function and function had affected structure to a point from which there was no recovery by the path of the original onset. Or let us look at this case another way. Granted that the original psychic conflict centred round the parental and homosexual complexes—in other words, that the original emotional disorder was due to emotional experience—I submit that the conflict was greatly exaggerated by the sense of physical incapacity, an incapacity which was successfully dealt with by physical means, and I add that until this secondary

[1] A paper read before the Section of Psychiatry of the Royal Society of Medicine on Feb. 12th, 1924.

source of conflict was dealt with it was impossible for the patient to resolve that part of her conflict which centred round her sex life. Furthermore, the most striking result of the surgeon's work was the lessened capacity for fear, presumably due to increased stability of all her motor reactions. This case seems to me an illuminating example of the action and reaction between thyroid function and emotional disturbance.

Another case of some interest is the following:—

D. C. H., aged 10½, brought to me for uncontrollable weeping. He was at a first-rate preparatory school where his environment was excellent. The boy lived with his brother and sister in the care of an aunt who appeared to be a first-rate foster mother. Both at home and at school he wept incontinently and without any apparent reason. His intelligence was said to be fully average. He was good at games and notably plucky. But all his masters reported the impossibility of putting up with a boy thus afflicted. During his interview with me he wept copiously and almost continuously. He said he cried because he thought of his father and mother. Now his father had been blown up at sea when the boy was about 5. He was said to have seen little of his father and never to have been at ease with him. In due course the mother married again. The step-father was particularly kind to the boy and the boy seemed fond of him. A year previously both mother and step-father were killed in a railway accident. On the physical side he was of normal physique, his pulse-rate was normal, but there was a definite thinning of the eyebrows on the external side.

The emotional situation was very intriguing, being complete down to the Hamlet touch, and I venture to surmise that many analysts would have felt justified in treating this patient. I put him on thyroid. In a week he was better; in six weeks he was perfectly normal; and I afterwards was able to confirm from my own observations the claim of his head master and of his aunt that he had been completely transformed.

The Function of the Thyroid.—But without choosing definitely pathological examples we may recognise the constant influence of the thyroid in the balance of ideation and expression. The thyroid has been recognised as the great anabolic reservoir of the whole system; it has been described by Leonard Williams as the female gland par excellence; it has been regarded—probably erroneously—as the determinant of bacterial immunity. Langdon Brown has suggested that it corresponds to the extravert principle in psychology. This last view falls in with my own conception of it as the gland of creation. We can at any rate, without indulging in speculation, recognise in the activity of the thyroid the principal determinant of expression. Now the sub-thyroidic introvert is an under-expressed individual who cannot fail to have numerous repressions and who easily falls a prey to an anxiety neurosis. I recognise in him primarily a case for thyroid administration, being convinced that a great deal of his anxiety will clear itself up without any analytical treatment when the balance between ideation and expression has been redressed. His psychic conflict consists largely in that sense of inferiority which arises from his inadequate powers of self-expression. In other words, the awareness of incapacity to meet life's demand for expression is the essential feature of his conflict, and it is a feature eminently amenable to the simplest form of therapeutic aid.

The Adrenals.—We cannot consider thyroid action exhaustively without discussing the adrenals as well. No correlation between emotion and physiological function is better established than the effect of fear on the "fight or flight" mechanism—that is, fear stimulates adrenal activity, this stimulates the sympathetic, the vagus equilibrium is upset, and the thyroid stimulated to increased secretion. Many of us, no doubt, recognised during the war the remarkable difference between what may be described as objective and subjective courage. One man would display the utmost heroism in the face of imminent danger, who nevertheless was tortured before by the anticipation or afterwards by the memory of the same danger. Another would appear unaffected before and after, and yet display terror in the presence of the actual danger. It seems to me that these differences must depend primarily on the responsiveness of the adrenal system. With some, fears in phantasy are sufficient to determine an adrenal reaction, while with others nothing short of objective danger produces this result. With some the response is biologically efficient, and with others it fails to produce an adaptation which is biologically favourable. Hence, in the great class of psychic conflicts which centre round the instinct of self-preservation, we may reasonably assume that an important element often consists in the awareness of adrenal inefficiency leading to the incapacity to adapt to situations of danger. I am not prepared to maintain that this factor, although it is largely a physiological one, is capable of being dealt with on a physical basis, but I am optimistic enough to hope that with greater knowledge of the subject this will come to be the case. I am encouraged in this hope by the undeniable effects of adrenal therapy in asthma. Here we have a condition in which analytical treatment has repeatedly revealed the psychogenic importance of fear complexes. It seems to me quite impossible to harmonise these two therapeutic methods of known value unless we picture the condition as a vicious circle in which fear promotes hyperadrenia and hyperadrenia promotes dyspnœa and dyspnœa promotes more fear, and so on.[1] The asthmatic is therefore an individual aware of his incapacity to meet certain demands for adaptation of a respiratory nature, and this awareness constitutes, in my view, a part of his psychic conflict which already we can, to some extent, treat on a physiological basis.

The Balance of the Autonomic Nervous System.—This problem of sympathetic stimulation is important enough to demand further discussion. The balance between sympathetic and parasympathetic activity must unquestionably be of no less consequence to the feeling tone of the individual than cerebral vascularity. The sympathico-tonic is neither more nor less incapable of meeting life's demands than the vagotonic. The first with his uncomfortable tension, his exaggerated response to stimulus, and his variable moods is as far from the mid-line of well-being as the second with his dull, relaxed, and apathetic lethargy that only intense stimuli can affect. The sympathico-tonic fears life because he cannot tolerate it when it becomes unduly stimulatory, whereas the vagotonic fears it because he can only tolerate it under these conditions. I submit, then, that both types are alike aware of their incapacity to adapt to a world in which stimulus is necessarily inconstant.

Interaction of Developing Glands.—Now, if we pass to a more general survey of the endocrine system, we are at once confronted by the antagonism between the glands of childhood and those of maturity. Our ultimate fate in life is so intimately bound up in this conflict that we are justified in surmising that it has far-reaching emotional implications. When and how the thymus and pineal yield to the gonads are the questions upon which turn not only our physical stature, but also our mental and, in some measure, our moral stature. Analytical psychology is largely taken up with the persistence of puerile characteristics. It is surely impossible for us to contemplate the tendency involved in such regression apart from the physical side. The high-grade defective is no doubt immune from the attentions of the intelligent analyst, but there are definitely subnormal types, many of them characteristically thymo-centric, whose thumb-sucking or other childish proclivities are apt to become the subject of solemn and arduous exploration. Without throwing any aspersions on the familiar psychological explanation of these manifestations, I venture to suggest that emotional immaturity might be approached—in certain cases, at any rate—from the point of view of physical

[1] The factor of specific sensitivity to foreign proteins is omitted not because I ignore it but because it seems irrelevant to the present discussion.

immaturity. We are all familiar with the inferiority sense of the high-grade defective, associated as it invariably is with a train of compensations in phantasy and behaviour. We recognise that in his case psychic conflict centres round his awareness of incapacity to meet the ordinary demands of life. We are prepared to admit that if any physical treatment could render him more efficient, his inferiority sense would be mitigated and its psychological implications reduced. I venture to suggest that there are many neurotic individuals who, while they cannot be classed as defectives, are yet immature psychologically and physically, and that their treatment should be regarded primarily as a problem of organotherapy, albeit a problem still unsolved.

The Sexual Aspect of Mental Disharmony.

The question of maturity brings us naturally to the consideration of the sex aspect of our subject. First of all let me say that if we are to see this problem in its true light, we must recognise that the biological objective of every individual must, from an evolutionary standpoint, be parenthood. I think we are often apt to lose our way in this wood because of the number of trees—chiefly phallic, of course—which constitute it. The gratification of the sex appetite is constantly referred to in terms which suggest that it is a terminus ad quem. This is surely superficial. The individual may, and constantly does, detach the hedonic from the procreative aspect of the function, but biologically the two are inseparable, and it is reasonable to suppose that unconsciously they are much more united than they are in consciousness. I think there is analytical evidence of this. If, then, we regard the achievement of parenthood as an impending demand for the male and the attainment of parenthood as an impending demand for the female, we see how readily psychic conflict may arise from any awareness of incapacity to meet this demand. Let us consider a few sex problems in this light.

Masturbation.—Let us first take masturbation. It is a mistake, I think, to regard it as mere gratification of an animal appetite. The capacity for sexual response, even of an autoerotic character, is to some adolescents proof that they have reached a phase of development which is at least on the path to maturity, and as such the practice has a reassuring value. Now an adolescent with normal self-confidence neither requires nor obtains any such reassurance. If, then, some adolescents differ from others in respect of this self-confidence, I submit that one ground of difference is in the gonad adequacy. It is true, of course, that much depends on the conscious recognition of the nature of the procreative demand and that when this recognition is premature the fear of procreative inefficiency is likely to follow, apart altogether from a sense of physiological inadequacy. But in certain cases the conflict that centres round masturbation derives its intensity from this awareness of incapacity to meet the impending demand to achieve or attain parenthood. Biologically the aim of every boy is to make his father a grandfather. Thus, and only thus, can he satisfy himself of his biological maturity. Social and business promotions have little influence; the youth may become the active partner in the business and replace his father there; he may attain to the social status which has ceased to interest his father, but from the broadest point of view he has not satisfied his urge to displace him until he also has begotten a son as his father begot him. Now regarded in this light the problem of dementia præcox becomes susceptible of a reasoned solution. Let me take an example recently seen.

D. S. is a law student, aged 22. Father, an active and intelligent man, who had forced the lad to ride when he was a small boy in spite of constant terror; subsequently, he had found fault with his inefficiency at school and at the age of 14 had threatened to horse-whip him. The patient has been a masturbator since puberty, the practice being associated with masochistic phantasies. He now complains that he cannot concentrate on his studies. His mind is perpetually obsessed by insoluble problems and impossible phantasies of a masochistic nature. This hebephrenic tendency is passing into his general life, and he is continually assailed by such characteristic questions as, "What would have happened if I had shut that door instead of leaving it open?" On the physical side we find that the patient needs to shave only once in two days; puberty came on at 16; at 12 he had mumps.

This latter statement may sound peculiarly irrelevant, but I must be allowed to reiterate my conviction that mumps occurring between the age of 10 and puberty, even without orchitis, has some deep significance in relation to gonad inefficiency. Now we see here a picture of a boy submitted from childhood to paternal repression and made to feel that maturity was an unattainable prospect and yet with every reason to wish to displace his father. But he feels physiologically inadequate; he regresses in phantasy more and more while deriving satisfaction as a result of masturbation, from the assurance that he is at any rate better than a child. If a motor-car fails to climb a hill it is always possible to say that the hill was too steep. But it is also possible to say that the engine was not sufficiently powerful. Unless we consider the problem in the light of the ratio of the power to the gradient, we naturally get no nearer to a solution.

That is why it seems to me that Mott's conception of dementia præcox as attributable to gonad inefficiency is just as unsatisfactory as the analytical theories which stress exclusively the emotional barrier causing the regression. In other words, I believe that the patient just described might have made a normal adjustment to life in either of two cases: (*a*) if his view of adult life in general and of paternity in particular had been less menacing; (*b*) if his gonad efficiency had given him that confidence which would have enabled him to believe in his ultimate capacity to make his father a grandfather. Now if this view be correct the therapeutic inference is obvious—namely, that it is our duty to attack the early case of dementia præcox not only from the analytical point of view, but also from the physical, and it is fortunate that something can be done in such cases by organotherapy.

Coitus Interruptus.—This is one sexual irregularity to which the psycho-analysts have given ample importance. While I do not claim that the consequent neurasthenia can be classified under the general heading of awareness of incapacity to meet life's demands, I should like to say two things. The first is that out of a considerable number of cases with this causation I can only recall one in which there was not a perfectly definite focal infection. Hence I profoundly distrust the treatment of this condition that ignores the toxic side. The second thing I have to say is that primarily coitus interruptus disintegrates the endocrine system rather than the emotional life. The act consists in a volitional interruption of the most powerful chain of reflexes in our nervous system, and its effect is mainly to throw a strain on the adrenals which in course of time results in adrenal exhaustion. This is my second reason for distrusting the psychotherapeutic approach to such cases, at any rate, as a first approach.

The Menopause.—The menopause presents problems in every department of medicine, with the possible exception of orthopædics. The menopause has necessarily the most profound significance from an emotional point of view for the woman whose maternal aspirations are unsatisfied. But in helping the patient to adjust to the cessation of her generative possibilities we must not ignore the endocrine side, for the withdrawal of the ovarian hormone has a repercussion on both thyroid and adrenals, which is of the greatest importance. A temporary vagotonia ensues which, if it replaces a previous sympathicotonia, determines grave physiological changes. To ascribe the neuroses of the menopause to psychic conflict is to express a partial truth.

Cyclothymia.—Finally, I would refer very briefly to the bewildering problem of cyclothymia and its

less frequent but more obvious manifestation of manic depression. I fancy there is no analyst of any experience but has been fooled by a cyclothymic. Without recognising the true character of the condition, we begin an analysis of a patient who appears to be suffering from an anxiety neurosis. Sooner or later the patient begins to improve, and if the analyst is human he begins to congratulate himself until he recognises the true situation either by undue exaltation or by an inexplicable relapse into depression. If we watch such a case over a period of several years, we recognise that the emotional reactions belonging to one phase have no relation to those manifested in the opposite phase; we note generally a fairly exact periodicity, and above all the fact that the transition from one phase to another is totally independent of emotional factors—favourable or adverse. Patients of this type are prone to be "cured" by whatever treatment happens to be in use at the time that the change comes. I cannot say whether the milder manifestations of cyclothymia are classed as neuroses by those who claim that every neurosis is caused by a psychic conflict, but I am very certain that the key to this problem will never be found in the realm of pure psychotherapy.

Conclusion.

In conclusion let me say that I have spoken, it may seem, in a derogatory way of analytical treatment. If I have done so, it is not because I am doubtful of its value or unconvinced by its successes. Rather do I feel that the therapeutic contribution of analytical psychology is too important and its possibilities too valuable to be exposed to criticism and even ridicule because of the apparent incapacity of certain analysts to correlate their psychological theory with physiological observation.

THE CULTIVATION OF TISSUES IN SALINE EMBRYONIC JUICE.

BY CHARLES A. PANNETT, B.Sc., M.D. LOND., F.R.C.S. ENG.,

PROFESSOR OF SURGERY, UNIVERSITY OF LONDON; DIRECTOR OF SURGICAL UNIT, ST. MARY'S HOSPITAL;

AND

ARTHUR COMPTON, D.Sc., M.B. R.U.I.,

FIRST ASSISTANT TO THE SURGICAL UNIT, ST. MARY'S HOSPITAL.

IT is 13 years since Harrison[1] first demonstrated that tissue cells would grow outside the body. It required little imagination to perceive that by this fundamental observation several fields of investigation were likely to be opened up; there was the possibility of old problems being attacked by new methods and of knowledge accruing which would almost certainly throw light on the mystery of malignant disease. The expected development of a technique by which tissue cells could be cultivated with the ease and certainty associated with the artificial growth of bacteria has failed to materialise. Many new facts have been learnt, but the plasma method worked out by Burrows, Carrel, Ebeling, and others has proved rather troublesome in its application to elucidate the problems of the growth of tissue cells. More than anything, a simplified but certain means of inducing cells to grow is a necessity if progress is to be made. This aspect of the subject was attacked in this country by A. H. Drew,[2] who in 1922 published the formula of an artificial culture medium from which plasma was eliminated. This was the starting-point from which proceeded the investigations dealt with in this communication. A great deal of time was spent at the initiation of the experiments by attempts faithfully to follow the description of Drew. It was found impossible to prepare the saline medium according to this investigator's account, owing to the fact that magnesium hydrogen phosphate $MgHPO_4$ is practically an insoluble salt. For this reason Drew's medium was discarded and a saline solution prepared, which, as far as possible, contained the inorganic elements found in plasma in similar concentrations. The next object in view was to ensure that the solution should have a hydrogen-ion concentration optimum for growth and that it should not easily change; that the solution, in fact, should be buffered. The carbonate-bicarbonate system, whilst a very desirable one, was rejected in favour of the phosphate system, the latter having the advantage of being made up of solutions which will stand autoclaving. The saline solution which has given the best results is made up as follows:—

Stock Solution A.

Sodium chloride NaCl	12·11 g.
Potassium chloride KCl	1·55 g.
Calcium chloride $CaCl_2$	0·77 g.
Magnesium chloride $MgCl_26H_2O$	1·27 g.
Water	100·00 c.cm.

Stock Solution B.

M/69 sodium dihydrogen phosphate $NaH_2PO_4{\cdot}H_2O$	5 c.cm.
M/69 disodium hydrogen phosphate $Na_2HPO_4{\cdot}12H_2O$	55 c.cm.

These solutions are autoclaved. For use take: Distilled water, 90 c.cm.; stock solution A, 4 c.cm., and autoclave. When cool, add 6 c.cm. of stock solution B with a sterile pipette. The resulting clear fluid will be referred to in future as the saline solution.

The pH of the solution lies between 7·3 and 7·6, using phenol red as the indicator. A comparison of the proportions of the several acids and bases in it with those found in plasma exhibits a fairly close agreement.

1000 c.cm. plasma of man contains*:—		The recommended solution contains:—	
Na_2O	4·290 g.	Na_2O	2·618 g.
K_2O	0·393 g.	K_2O	0·360 g.
CaO	0·155 g.	CaO	0·155 g.
MgO	0·101 g.	MgO	0·100 g.
Cl	3·612 g.	Cl	3·695 g.
P_2O_5 (in animals), 0·052–0·085.		P_2O_5	0·082 g.

* R. H. A. Plimmer: Practical Organic Biochemistry, 1915.

The only discrepancy is in the percentage of sodium. This is accounted for by the absence of carbonates in the fluid, a deficiency imposed by the necessity for sterilisation by autoclaving. Owing to the fact, however, that there are the weak phosphoric acid radicals present in the solution, in an amount agreeing with the proportions in plasma, the number of dissociated active, and therefore, from our point of view, significant sodium ions is probably not widely different from that in blood plasma.

It may well be asked whether the solution contains the phosphates in a high enough concentration to be sufficiently buffered for the purposes of growth. The addition of acid to the medium alters the pH according to the following experimental findings:—

Vol. of Solution Used, 5 c.cm., pH 7·4.

Drops N/100 H_2SO_4 (1 drop = 0·025 c.cm.)

Drops	pH	Drops	pH
1 gives	7·2	6 give	6·8
2 give	7·2	7 ,,	6·8
3 ,,	7·0	8 ,,	6·6
4 ,,	7·0	9 ,,	6·6
5 ,,	6·9	10 ,,	6·6

Indicator phenol red in each instance.

When acid is added to distilled water under the same conditions the pH changes very much more quickly, as the following result shows:—

Vol. of Water Used, 5 c.cm., pH 7·1.

Drops N/100 H_2SO_4 (1 drop = 0·025 c.cm.)

Drops	pH	Drops	pH
1 gives	6·6	8 give	4·5
2 give	5·0	9 ,,	3·8
6 ,,	5·0	10 ,,	3·5
7 ,,	4·8		

Drop 1: Indicator phenol red. Drops 2 to 10: Indicator brom-cresol blue.

The buffering of the saline solution is seen to be not of a high order, and although only weak acids are produced by metabolic activity, it was considered

[1] R. Harrison: Jour. Exp. Zool., 1910, ix., 786.
[2] Jour. Exp. Path., 1922, iii., 20.

to possess rather a narrow margin of safety. Tissues will grow if the proportions of phosphates, and so the degree of buffering, are increased even up to M/50 concentration, but this raises the amount of the phosphate to an undesirable figure, and was proved to be quite unnecessary when tissues are grown in embryonic juice as described below, for the buffering of this juice is much greater than that of the original solution.

The following experiment shows this:—

Vol. of Saline Embryonic Juice Used, 5 c.cm., pH 7·3.

Drops N/100 H_2SO_4 (1 drop = 0·025 c.cm.)

Drops		pH	Drops		pH
1	gives	7·3	9	give	7·0
2	.. .. ..	7·3	10	.. .. ..	7·0
3	.. .. ..	7·2	11	.. .. ..	7·0
4	.. .. ..	7·2	12	.. .. ..	7·0
5	.. .. ..	7·2	13	.. .. ..	7·0
6	.. .. ..	7·2	14	.. .. ..	7·0
7	.. .. ..	7·2	15	.. .. ..	6·9
8	.. .. ..	7·1	16	.. .. ..	6·8

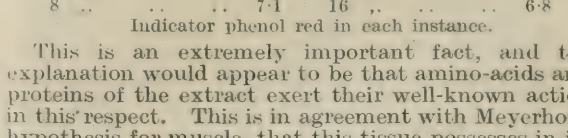
Indicator phenol red in each instance.

This is an extremely important fact, and the explanation would appear to be that amino-acids and proteins of the extract exert their well-known action in this respect. This is in agreement with Meyerhof's hypothesis for muscle, that this tissue possesses in its colloids more effective buffering substances than in its inorganic salts.[3] The pH of the drop of fluid after growth in it has taken place for 48 hours was found by a perhaps rather inexact estimation with phenol red to be unchanged. The technique employed for obtaining cultures differs somewhat in detail from the method of other investigators and will now be described.

Apparatus Required.

(1) A box such as has been described by Drew is of inestimable value. With its aid cultures have been made throughout these investigations in a laboratory in which there is a great deal of human traffic. Yet an infection is a rarity. The box can safely be left open on the side facing the operator, and, if the work be done on a glass slab or tiled bench, it is of advantage that there should be no bottom to it. Before beginning, the inner surfaces of the box are simply wiped with a clean wet cloth (Fig. 1). Other requisites

FIG. 1.



Box and apparatus for making cultures in a laboratory where much other work is carried on.

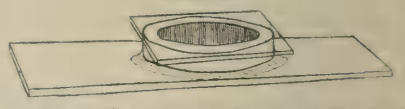
are: (2) a metal plate on which to perform manipulations with a rod running parallel to it to act as a rack; (3) a metal rack for supporting pipettes and needles; (4) microscopic slides; (5) glass squares, made by cutting microscopic slides into three equal parts; (6) glass rings, 20 mm. in diameter and 2 mm. thick, ground top and bottom; (7) small wool-plugged centrifuge tubes; (8) pieces of glass tubing, wool-plugged at each end, for drawing out in the blowpipe to make pipettes; (9) a cement made up of equal parts of paraffin wax, melting point 52° C., and vaseline (a number of cements have been tested; pure paraffin wax is pervious to air and allows evaporation to take place through it; mixed with an equal quantity of vaseline it has not this drawback); (10) carbon dioxide snow, easily prepared from a cylinder of compressed gas; (11) forceps and fine scissors; (12) glass blocks; (13) small Petri dishes (14) two metal needle-holders and No. 10 Hagedorn needles. Nos. 2, 3, and 14 are sterilised by flaming 4 to 8, 12 and 13 by dry heat at 150° C., the instruments by boiling or dry heat.

[3] Pflüger's Arch., 1922, cxcv., 22.

Method of Setting Up Cultures.

Embryonic mouse and chicken tissues have been used. The latter are the more convenient, and have the advantage that the age of the fœtus is accurately known. The blunt end of an incubated egg having been washed over with alcohol, the shell is cracked and an opening made large enough to extract the embryo, which is put into a small Petri dish, where it is washed in the saline solution. It is then placed in a hollow glass block, where it is cut up with scissors until it becomes a mush. This is transferred by pouring into a sterile wool-plugged test-tube. The tube is then inserted into the carbon dioxide snow where its contents quickly freeze hard. After thawing the process is repeated. Approximately an

FIG. 2.



Slide, cell, and covering-glass square in readiness for placing in the incubator.

equal volume of saline solution is then added to the thawed product, which is shaken up well, and sedimentation allowed to take place for a few minutes. The supernatant liquid pipetted off, centrifuged to clear it further, and diluted with an equal volume of saline solution, constitutes the culture-medium. Embryos of 10 to 14 days are most convenient for making the saline juice.

The cells in which the tissue is cultured are made as follows. In a porcelain dish or seamless metal syringe-box, some cement is melted and heated enough to ensure its sterility. A glass ring is then seized with fine forceps, plunged into the molten cement, and dropped on to a sterilised microscopic slide, which is gently warmed on the under surface to render the junction of ring and slide quite impassable to air. The slide is then placed ring downwards, leaning on the rack and metal stage. The tissue to be cultivated is dissected from the embryo and, after rinsing in the saline solution, is cut up into small pieces by means of the Hagedorn needles, which have, of course, cutting edges. The prepared slides are then arranged on the metal stage, rings upwards, and on each is dropped from a pipette a small volume of the culture-medium. With the needles a piece of tissue is placed on each slide and the drops of solution spread out by manipulation. Unless the tissue adheres to the glass, growth will not take place. Adhesion fails to occur if the drop be too large. Each cell is then closed by covering it with a heated glass square. The whole cell is then inverted so that the drop of culture-fluid hangs dependent from the microscopic slide. The preparations are placed thus in the incubator. The cell is seen in Fig. 2.

Results to be Expected from Exhibition of This Technique.

If the above instructions be scrupulously followed, growth of fibroblasts can be confidently predicted in nearly every preparation (see Figs. 3–6). Frequently there is 100 per cent. of growth; the average works out at approximately 85. Growth can usually be detected in 18 hours, and it reaches its maximum intensity ordinarily in about 48 hours. Tissue cells, however, are far less robust than bacteria, and are much more exacting in their requirements. The method is pre-eminently suitable for the growth of fibroblasts. Since observations under the microscope must take place through the thickness of a microscopic slide, high powers cannot be used. The preparation of stained specimens is, however, very much

simpler and more easy than when cover-glasses are employed. An excellent fixing medium is 5 per cent. acetic acid in 70 per cent. alcohol. Staining is done by Heidenhain's iron hæmatoxylin method.

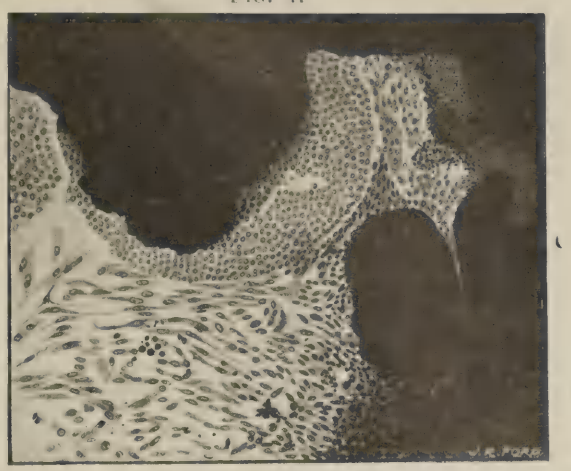
Growth will not continue for more than about three days after it has begun. Then signs of degeneration appear. What is the cause of this cessation of growth? The possibilities which have been considered are disappearance of nutritive material, lack of oxygen, the accumulation of injurious products of metabolism. The problem of continued growth in saline juice resolves itself into the discovery of a

FIG. 3.

Fibroblasts growing in saline embryonic juice. Fifty-three hour culture of muscle tissue from eight-day chick embryo.

device for maintaining the conditions in being which were present at the initiation of the experiment. A further communication on this subject will be made. It suffices here to say that the degenerative processes from our observations are due to the accumulation of metabolic waste material in the medium. With the technique described it has not been found possible to get continued growth for longer than six to seven days, though there is not the slightest doubt that this problem can and will be solved, so that maintained growth will be as possible as with plasma technique. Those who have worked at tissue culture will recognise how much more convenient is the examination of growths when fibrin is absent and the cells are all arranged in one extenuated sheet. The development of a technique along these lines is much to be desired.

FIG. 4.

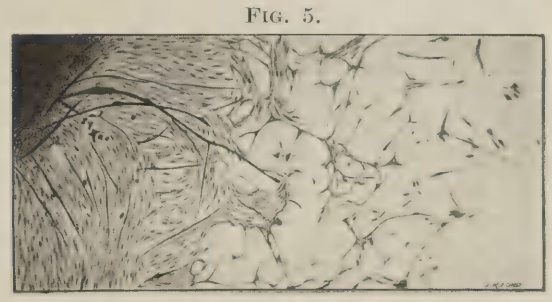


Growth of fibroblasts and epithelium from the subcutaneous tissue and skin of a six-day chick embryo. Forty-eight hour culture.

The Part Played by the Saline Medium in the Growth of the Tissue.

The saline solution is not to be considered as a culture-medium sufficient in itself. It is true that growth will often take place, sometimes quite

FIG. 5.



Fibroblasts and embryonic muscle fibres growing from a piece of muscular tissue of an 11-day chick embryo, cultivated for four days. The piece of tissue was transferred to a new cell after 48 hours.

vigorously, if a piece of tissue is simply placed in the solution alone, but its occurrence is not to be depended upon. The essential nutritive material is contained in the embryonic juice. Cultures can be obtained if normal saline solution made with tap-water be substituted in preparing the extract, but the degree of success attending its use is rather uncertain. For one thing, the pH of normal saline made in the ordinary manner is not very constant, and apt to be too alkaline for ideal conditions; whilst washing the tissues in it must partly deplete them of all those inorganic constituents which are missing in its composition but

FIG. 6.

A part of the preparation shown in Fig. 5 under a higher magnification.

present in the lymph which bathes the tissue. For these reasons, a saline solution of certain composition approximating to that of plasma, as far as inorganic constituents are concerned, of known pH, and buffered to some extent, appears to be a much preferable medium to employ. When a certain amount of growth takes place without embryonic juice, it seems fairly clear that the necessary food material is derived from the central part of the implanted tissue which dies and macerates. It is an uncertain process upon which to rely.

This communication concerns itself solely with technique. It is not the place to describe the behaviour of cells in artificial culture. The biological needs of the growing cell are very imperfectly known. Yet step by step the conditions which must exist will eventually be discovered. In such a quest the standardisation of the controllable factors is essential. This work is an attempt to effect this in the case of the inorganic constituents of the medium in which the tissues are grown. It has been done as part of the activities of the Surgical Clinical Unit at St. Mary's Hospital in the constituent laboratories of the Pathological Institute, facilities having been generously accorded by Sir Almroth Wright, Dr. John Freeman, and Prof. B. J. Collingwood, to whom we offer our most grateful thanks.

THE ACTION OF BAYER "205" IN TRYPANOSOMIASIS.[1]

BY F. K. KLEINE, M.D.

BAYER "205" is a complex organic body which contains neither arsenic, mercury, nor any other metal and thus differs from other remedies so far used in sleeping sickness. Chemo-therapeutically, it is standardised to act in such a manner that a mouse infected 24 hours before with nagana trypanosomes can be permanently cured of trypanosomiasis by a single injection of 1/10 mg. per 20 g. body-weight. Clinically, results as good as those recorded by Dr. G. C. Low and Dr. P. Manson-Bahr[2] have been obtained by other investigators.

In a recent expedition to Africa an experimental station was established at Ndombo, a negro village in the neighbourhood of Mpika, and later in the Belgian Congo. The parasites are transmitted by tsetse flies, but not directly. A fly feeding first on an infected and then on a healthy person does not infect the latter with its proboscis as with a vaccinating lancet. Before the fly becomes infective the parasites it has ingested must undergo a certain development which requires several weeks for its completion. Thus the parasites and glossinæ stand in a similar relation to each other as do malaria parasites and anopheles.

The trypanosomes in animals studied in this expedition were (besides *T. theileri*) *T. brucei*, *T. congolense*, and parasites of the *T. vivax* group. These can be differentiated by their morphology and specific pathogenesis. In human beings two kinds of trypanosomes may be observed, *T. rhodesiense*, the producer of the sleeping sickness in Rhodesia, transmitted by *Glossina morsitans*, and *T. gambiense*, the producer of the ordinary sleeping sickness on the Congo, transmitted by *Glossina palpalis*. The morphological difference of the two kinds may not be constant. The fact that two species of *Glossina* are involved does not disprove the identity, as both these flies are able to transmit both trypanosomes.

Attempts to Induce Prophylaxis in Cattle.

From the point of view of the economic life of South Africa, as well as that of the Congo, it is of special importance to know whether it is possible to protect cattle prophylactically against trypanosomiasis so that valuable animals can be driven without danger through infected areas to healthy places. For this reason it was attempted to find out first of all how long after the administration of Bayer "205" the prophylactic protection lasted.

The methods employed in Rhodesia were as follows: Fly-catchers were sent out to collect a few hundred flies which were allowed to feed on animals previously treated. On the following day the flies were fed on a healthy dog. If the dog became infected it was a clear indication that the cattle had also been bitten by infective flies. In the Belgian Congo, where a larger number of cattle were available, animals treated with Bayer "205" were allowed to be bitten by flies under natural conditions. As soon as trypanosomes were found in the blood of the control animals, all animals were withdrawn from the fly-belt and transferred for further observation to a place which was free of flies. As a result of these experiments in Rhodesia and on the Congo it was shown that even after large doses of Bayer "205"—e.g., 10 g. for a bullock of about 5 cwts., repeatedly given, it was not possible to prevent infection by trypanosomes. *T. theileri*, as well as *T. vivax* are scarcely influenced by the drug. The development of *T. congolense* and especially *T. brucei* is suppressed for a short period and, sometimes after several weeks, the trypanosomes will reappear.

Special attention was paid to the action of the drug in *T. brucei* infections. In its numbers in the blood as well as in its capacity for development this parasite was restrained in such a way that to prove its existence in the blood of cattle it was necessary to inoculate monkeys with large amounts of the blood. Even after its transmission to monkeys, there were certain indications of the continuation of the action of the drug. A normal, uninjured strain of *Trypanosoma brucei* can easily be detected microscopically in monkeys' blood, but parasites originating from the treated cattle could be found only with difficulty and sometimes they would disappear entirely for many days. Their virulence was reduced and the enlargements of the spleen in diseased animals was only slight. In spite of their slight virulence, the trypanosomes did not react to the dose of Bayer "205" generally effective. In experiments of this kind it is imperative to ascertain for each species of animals the dose *which under normal conditions* exercises an influence on trypanosomes, the sensitiveness of the parasites to a drug depending largely on the type of animal host and must not be estimated on the basis of weight when different species of animals are under consideration.

Again, while it is possible by injections of Bayer "205" to render mice immune against subsequent infections of trypanosomes for months, a complete protection in cattle has not yet been obtained. The diminished virulence of the trypanosomes resulting from the action of Bayer "205" was, however, noticeable in the experimental cattle. Combinations of this drug with tartar emetic gave greatly improved prophylactic and therapeutic results. It is still too early to draw any conclusion as to the possibility of practical prophylaxis.

Experiences in Treatment of Trypanosomiasis in Humans.

A more definite demonstration of the value of the drug is afforded by the experience gained in treating human trypanosomiasis. Three stages of sleeping sickness were distinguished: (1) blood infection, (2) enlargement of the glands, (3) infection of the nervous system. Stages 1 and 2 are most important from an epidemiological point of view, since in the initial stages natives go about without knowledge of their illness and form a constant source of re-infection for the flies. Whether patients suffering from sleeping sickness can be spontaneously cured is not known, but on the analogy of other diseases this seems possible.

Results in Rhodesia.—In Rhodesia 35 patients were treated. How many belonged to the third stage cannot

[1] An abstract of a paper read on Feb. 21st to the Royal Society of Tropical Medicine, in whose Proceedings the paper will appear in full. [2] THE LANCET, 1922, ii., 1265.

definitely be ascertained, as a lumbar puncture was rarely made before the beginning of treatment, but the percentage is probably a high one, since about half the patients had to be carried into camp. The diagnosis was made by demonstrating parasites in the blood and a subcutaneous injection of 1 g. of Bayer "205" in 5 c.cm. of warm physiological solution of sodium chloride was given under the skin on the back near the spine, at the height of the middle of the scapula, and was repeated twice at an interval first of 10 and then of 18 days. Patients with trypanosomes in the cerebro-spinal fluid (C.S.F.) or showing a relapse on blood examination were given a fourth and fifth injection. The pain following the injections varied—some experienced very little discomfort. Sometimes an inflammatory swelling occurred, disappearing in a few days, and formation of abscesses occurred in four cases.

The clinical results of the treatment were controlled by frequent blood examinations. One European who discharged himself prematurely died later on from sleeping sickness, and one native died suddenly and unexpectedly seven days after he had received his fourth injection, no autopsy being obtainable; but the remaining 33 patients showed after a few weeks a surprising improvement in bodily strength. In October, 1922, about three months after the commencement of treatment, lumbar punctures were made in 21 patients, and in 8 of these trypanosomes were found in the C.S.F., the blood being free from parasites. Whether the trypanosomes finally die off or whether an aggravation of the clinical condition eventually occurs cannot yet be stated. The cases in which trypanosomes were found in the C.S.F. were those who originally presented symptoms of infection of the central nervous system, the symptoms having almost entirely disappeared. Six patients who still had trypanosomes in the lumbar fluid gave a general impression of vigour and performed heavy work. It can only be assumed (1) that Bayer "205" is able to exercise some influence upon the parasites in the brain, and (2) that the trypanosomes which are not killed off at once in the body by its agency are greatly reduced in virulence.

On April 13th, 1923, the death of three treated persons was reported, two of them having been previously noted as being severely affected, and the third having had an abdominal tumour which may have caused her death. The remaining 30 patients were reported to be alive and apparently well, which results can be regarded as exceedingly satisfactory, the period of observation after treatment being between six months and a year.

Results in the Congo.—Of 150 patients under observation in the Congo most belonged to the first and second, and about 10 per cent. to the third stage. The diagnosis was arrived at by microscopical demonstration of living parasites in fluid from enlarged glands in the neck or in the blood; the technique will be found in the full report of the paper. Of 32 patients, 24 had trypanosomes in glands *and* blood, 4 only had them in the glands but not in the blood, and 4 in blood and not in glands. In each patient only one blood preparation and one glandular preparation were examined. Generally speaking, if there are parasites in the glands, they can also be found in the blood. In patients not previously treated it is unnecessary to resort to lumbar puncture for a diagnosis.

In order to determine whether trypanosomes are present in the C.S.F. of patients without nervous symptoms, lumbar punctures were made on 24 mentally normal patients, the result being uniformly negative. Even in psychically abnormal patients trypanosomes were not always to be found in the C.S.F. In such cases, however, the number of lymphocytes is always increased. The patients in the Congo received *intravenous* injections on the first, third, and fifteenth day, 1 g. of Bayer "205" at each injection. The drug was dissolved in 10 c.cm. of rain-water and injected into a vein of the arm. Children received a proportionately smaller dose—viz., 0·4 to 0·6 g.—in the jugular vein. Patients seriously ill and those with trypanosomes in their C.S.F. were mostly treated at ten-day intervals, but more than five injections were never given. Patients prefer intravenous to subcutaneous treatment, as it is painless. Care was taken to use an initial large dose to prevent the parasites from getting accustomed to Bayer "205."

In all persons in the first and second stage of the disease a feeling of improvement was soon noticeable. Strength returned and the glandular swellings subsided. Among 96 patients whose blood was examined every few days for five months after the third injection trypanosomes were found only in the blood of two children, two or three months after the third injection. Whether these were actual relapses or fresh infections cannot be decided. A remarkable improvement occurred in two maniacal patients; of two others, one died accidentally and the other one ran away. Seven patients in the third stage of the disease who had previously been treated with other remedies showed no improvement clinically under Bayer "205"; in two of these patients trypanosomes were found in the C.S.F., but the blood of all of them was permanently free from parasites. Similar results were not obtained by us with atoxyl, salvarsan, or antimony, the trypanosomes always returning to the blood within one to three months.

Certain Disadvantages.—The albuminuria which follows injections of Bayer "205" tends to disappear after a time. Injections should not, however, be repeated too often. The parasites get accustomed to the drug, and its action upon the host cannot be ignored. In cattle treated too intensively a reduction in the coagulability of the blood was followed by inflammation of the kidneys, fatty degeneration of the liver, and jaundice of all tissues. When, after four injections of Bayer "205," trypanosomes reappear and remain in the blood a change to antimony should be made. The actual percentage of patients cured by Bayer "205" cannot yet be stated, but the patients will be re-examined in the course of the year. At any rate, at the present time Bayer "205" would seem to be the best remedy for sleeping sickness.

No definite proposals are made as to the systematic treatment of an epidemic, since various methods can be employed in various parts of Africa. In some parts the natives can be moved from threatened districts, in others the glossinæ may be stamped out. Drug treatment is of importance, since the blood of infected patients can be sterilised for some time, thus withdrawing from "healthy" flies the source of infection.

THE USE OF SILVER FILIGREE IN THE RADICAL CURE OF HERNIA.

BY PERCIVAL P. COLE, M.B., CH.B. BIRM., F.R.C.S. ENG.,

SURGEON TO THE SEAMEN'S HOSPITAL, GREENWICH, QUEEN MARY'S HOSPITAL FOR EAST END, AND THE CANCER HOSPITAL.

IN a recent monograph, "Hernia and its Radical Cure,"[1] the use of silver filigree has been uncompromisingly condemned. The author's conclusions are based entirely on objective evidence, for it is admitted that he has had no personal experience to guide him. The book has been favourably reviewed in the medical press, and the case against the filigree therein presented must be regarded as authoritative, for by silent acquiescence medical journals have approved the author's thesis. THE LANCET[2] says, "comparisons of various procedures are made in a fair and broad-minded spirit," and again, "metal filigrees are condemned, and the author's opinions are confirmed by the increasing rarity with which such materials have been employed in recent years." It is my purpose, first, to defend the filigree, by endeavouring to refute the objective evidence

[1] By J. Hutchinson. Oxford Medical Publications.
[2] THE LANCET, 1923, ii., 333.

brought against it in this monograph, and secondly, to urge its use by the presentment of subjective evidence of personal experience.

To arrive at a correct assessment of an author's conclusions, importance must attach equally to the substance of the objective evidence, and to the method of its employment. What is the substance of the case against the filigree? Do the author's methods of presentment merit the approval thus expressed? The case against the filigree is not gradually unfolded, the evidence is not carefully elaborated before the conclusions arrived at are stated. The author's attitude is quickly and forcibly expressed, and the reader is prejudiced against the method in that the surgeon will, it is stated, be led to resolve "under no temptation will I bury silver wire—or silver filigree either—in a patient's groin." This resolution, it appears, will be forced upon the surgeon by the perusal of Bloodgood's cases published in 1900, and of the late Mr. C. B. Lockwood's cases published in 1905.

The Basis of Criticism.

Now, however eminent the observers, and however convincing their observations, no reasonable surgeon will be bound by the findings of 20 years ago, unless the conditions of practice are essentially the same. It is not too much to say, I think, that a surgical genius, though a boon to his own generation, is sometimes a curse to posterity. His blindly admiring disciples uphold his teaching and advocate his methods of practice long after their utility as an end-product has been superseded. The surgical history of the recent war provided outstanding examples of this blind adherence to methods adapted to the technical facilities of a past era. That the conditions of practice 20 years ago were very different from those that now obtain will be readily conceded. Surgical technique has progressed very considerably, particularly in the domain of foreign body surgery. The Lane plate and the bone graft are outstanding products of modern practice. That the author's sweeping condemnation is entirely unjustified by the references indicated is clearly established by investigation of their substance.

Bloodgood's cases refer to the use of buried silver wire sutures, a very different matter from the implantation of a filigree. Even in this respect it is interesting to note the following passage from Bloodgood's publication.[3]

> Clinically, the results in the healing of the wounds have been much better since the introduction of silver wire and silver foil. Before the introduction of silver wire, 116 cases of hernia had been closed with silk; in 28 of these cases (24 per cent.) there was more or less suppuration. Since silver wire was first used there have been 330 operations with 14 suppurations (4·2 per cent.).

In those days, then, silver wire was found to be a less irritating foreign body than silk! Bloodgood also states that rubber gloves had only been used by him and his assistants as a routine measure since 1897.

The Lockwood reference I have been unable to trace, but in the volume referred to[4] Lockwood discusses the advantages and disadvantages of rubber gloves, and advises against their use in many operations as they interfere too much with tactile sensation.

Discussion.

The style of this initial criticism scarcely augurs well for an impartial survey. In the further discussion of the use of filigree some purely supposititious and unbacked objections are cited. It is stated, for instance, that there is a risk of the filigree "shifting in position or crumpling up, so to speak." No filigree should shift its position once it has been snugly adapted to its bed. Any change of position is an indication not of defective operation but of a defective operator. Again, before crumpling can be urged as an objection it must be shown: (1) that a filigree does crumple, and (2) that such crumpling is detrimental. The construction of the filigree is such as to determine a certain flexibility. This flexibility is of considerable advantage, for it permits an accurate and automatic adaptation of the filigree to the bed in which it lies.

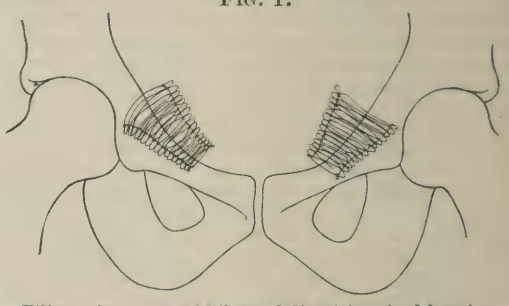
The answer to this objection is, then, first, that the filigree does not crumple; secondly, that its natural flexibility is one of its essential characters. It would appear that this crumpling is a feature alleged to characterise the behaviour of the filigree more particularly in the groin, for it is stated that—

> In the groin (femoral and inguinal hernia) where flexion at the hips, &c., infallibly produces kinking of a rigid body like a sheet of filigree such insertion must be ill-advised.

Incidentally, the discrepancy between the crumpling of the filigree in one passage and its alleged rigidity in another is sufficiently striking.

To controvert this crumpling objection I reproduce tracings from X ray photographs of filigree cases

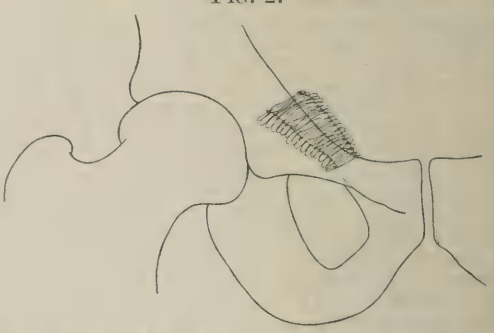
FIG. 1.



Filigree in a case of bilateral direct inguinal hernia.

taken some months after their insertion. In the one case (Fig. 1) the man, a stout seaman, was the subject of bilateral direct inguinal hernia. If ever alleged flexion of the hips could have produced a crumpling up of the filigree it certainly would have done so in this case. In Fig. 2 a tracing is shown of a filigree

FIG. 2.



Filigree in case of oblique inguinal hernia, eight months after insertion.

eight months after its insertion. Flexion of the hips constituted in this case a normal attitude at work, and it is obvious that no crumpling had occurred.

One of the strongest points brought forward to emphasise the alleged defectiveness of the filigree operation is the increasing rarity with which it is employed. This increasing rarity is based on the figures obtained from one of the largest hospitals in Great Britain between the years 1914 and 1919: the name of the hospital is not mentioned. "After 1919 not a single filigree," it is stated, "has been used in any hernia case during the last three years. The only deduction to be drawn is that it has been found to be an unsatisfactory method." It appears to me that such a deduction is entirely unjustified, and that other equally satisfactory explanations might be adduced. As opposed to these figures are those obtained from the Seamen's Hospital at Greenwich, which is by no means one of the largest hospitals in Great Britain and probably has no more than one-third as many surgical beds as that instanced by

[3] Johns Hopkins Hospital Reports, 1899, p. 225.
[4] Transactions of the Medical Society, 1905, Aseptic Surgery in Theory and Practice.

the author. From May 1st, 1922, to April 30th, 1923, filigrees were inserted in 26 cases.

Discussing the use of filigree in the radical cure of ventral hernia, it is stated that—

"Since 1918, so far as I can ascertain, not a single case has been treated by the insertion of filigree by any member of a very large surgical staff. Such a verdict after full experiments of a much-vaunted method renders further comment unnecessary."

"During the years 1910 to 1917 filigree was inserted in a considerable number of cases at the London Hospital, and it had also to be removed in a considerable number."

Now as far as I can ascertain at the Seamen's Hospital, Greenwich, no trouble of any kind has supervened in the 26 cases in which filigree operation was employed during the period of time indicated. My own contribution to this number is 12 cases, and my contribution in other hospitals and in private practice increases the total to double that figure. Throughout the whole of my experience I have only once had occasion to remove a filigree, and that experience will, I feel sure, be endorsed by many other surgeons who have adopted its use and appreciated the scope of its application. Mr. Souttar, himself a surgeon at the London Hospital, is quoted as endorsing all the author's objections to the use of the filigree. The reference given is "Souttar, *Brit. Med. Jour.*, Nov. 25th, 1922, p. 1024," under the heading of the Operative Treatment of Difficult Hernias. On consulting this reference we find that what Mr. Souttar actually did say is: "And the wire filigrees of McGavin have achieved conspicuous success."

In this article Mr. Souttar draws attention to another method dealing with difficult hernias, and it is surely more than likely that a method elaborated by a London Hospital surgeon should be employed by other surgeons at the London Hospital.

What is to happen to cases of hernia in which an adequate barrier consisting of the patient's own tissues cannot be constructed? No one, even the most ardent advocate of the filigree, pretends that its use is indicated where such an effective barrier is available. The whole question hinges on operability rate. One gathers from Mr. Hutchinson's work that cases in which the patient's own tissues are so defective as to preclude a reasonable hope of radical cure by their means, must be relegated to the weary army of truss wearers. I can find, in perusing this book, no accessory means of ridding these patients of their infirmity. Some interesting side-lights on this question of operability may fruitfully be considered. Thus on p. 37 the question of the advisability of operating on recurrent hernia is discussed, and the author's views are supported by the narration of the gloomy happenings that took place in the cases of 11 recurrent inguinal hernias operated on in St. Thomas's Hospital in 1896; seven cases suppurated, and two of these died of septic peritonitis. This narrative may mark a stage in the history of surgery, but that it can have any possible effect in deciding for or against the question of operability in recurrent hernia is surely incredible.

Again, in discussing direct inguinal hernia, the author's outlook is very conservative:—

"Some surgeons hold that direct inguinal hernia is not suitable for the operation for radical cure as recurrence is so apt to take place after it. However, I have seen several cases in which success was obtained and believe it is worth while to make the attempt provided the patient is a suitable one, that is, he is in good general health, not too fat, and free from any contributory causes, such as stricture of the urethra, &c."

In umbilical hernia the indications for operation are particularly vague. "I would urge," says the author, "that every case that is at all hopeful should be submitted to operation for radical cure." The hopefulness or otherwise of a particular case can only be guessed at by a description of a typical case, which is "a hernia the size of one's fist, irreducible for long, occurring in a stout and middle-aged woman."

What is the attitude of the filigree user towards these types of hernia? It is this: Recurrent and direct inguinal hernia, umbilical and ventral hernia, are operated on as a routine, and the patient's general condition must be very bad to determine a refusal. A considerable proportion of the cases of hernia at the Seamen's Hospital are direct cases, and were the surgeons at that institution to adopt a conservative attitude, these men would be deprived of their means of livelihood. Owing to the particular and restricted nature of the practice at the hospital, the failures return to the home of their origin. I have seen and heard of many recurrences after ordinary operations; I have never seen or heard of a case in which filigree implantation resulted in failure in any type of hernia.

Points in favour of the filigree are almost ignored, but the following grudging admission is made:—

"It should be noted in opposition to the unfavourable judgment given above that the insertion of silver filigree has had (and possibly still has) warm advocates."

In another part of the book, however, Mr. Lawrie McGavin's article on hernia in Choyce and Beattie's "System of Surgery" is quoted. Mr. Hutchinson expresses considerable surprise that the use of filigree should be so warmly advocated in such a modern work. In the last edition of this same work (Choyce and Beattie) the article on hernia has been revised by the editor, Mr. C. C. Choyce, and advocacy of the filigree is no whit less warmly urged.

Case Records.

The filigree, then, not only has had, but still has warm advocates: Lawrie McGavin and C. C. Choyce have recorded their faith in print, and I may be allowed perhaps to rank myself among the number. I propose to justify my attitude in this respect by the inclusion of some typical cases recently operated on.

Female aged 47. Appendix removed 1912, emergency operation for septic peritonitis 1919. Four months later operation for adhesions; 1920–22 gradual growth of a hernia through the left paramedian incision. She was admitted under my care, operation having been refused by other surgeons. She had a large hernia protruding through an aperture 2½ inches in diameter. The abdominal wall was a mass of scar tissue. A filigree was inserted measuring 4 inches by 4 inches. The operation took place on Nov. 24th, 1922, and she was discharged on Jan. 4th, 1923. No sign of recurrence; wound soundly healed.

Female, aged 48, very stout, with a large ventral hernia in the mid-line reaching from the umbilicus to the pubes. A filigree, 6 inches by 4 inches, was inserted, as extensive dissection demonstrated that patient's own tissues could not be utilised to form an effective barrier. Patient has been perfectly comfortable, the abdominal wall is quite sound.

Seaman, aged 36, very stout; bilateral double direct hernia with no definite sac, but diffuse and pronounced bulging of the whole posterior wall of the canal; conjoined tendon very poorly developed. This patient, contrary to usual custom, was operated on with a general anæsthetic as he refused stovaine intrathecally. He developed bronchopneumonia and coughed continuously for a fortnight. Filigree both sides (Fig. 1); wound healed normally.

Seaman, aged 59; large direct inguinal hernia, containing portion of bladder and a large mass of extra-peritoneal fat. Conjoined tendon very poorly developed. Filigree inserted. Convalescence uneventful.

Surgeon; left inguinal and femoral hernia, small oblique inguinal sac, large direct protrusion of extra-peritoneal fat; large mass of extra-peritoneal fat forced through femoral ring into thigh. Operation Sept. 26th, 1922; stovaine intrathecally, no general anæsthetic. Filigrees inserted. Since operation he has not hesitated to perform actions which incur considerable stress, such as cranking his car, carrying heavy weights, &c. No sign of any recurrence; operation area is perfectly sound.

Pathologist; oblique inguinal hernia with diffuse bulging of the posterior wall of the canal; conjoined tendon poorly developed. Operation January, 1923 (Fig. 2); convalescence uneventful. No sign of recurrence, operation area quite sound.

Ex-sergeant-major, Royal Engineers, aged 28; right recurrent inguinal hernia; operated on twice in the army, worse after each operation. When demobilised wished to enter Colonial Service, but was rejected by colonial medical officer. Operation August 23rd, 1923. The groin was a mass of scar tissue; cord verified, and isolated with great difficulty; large direct inguinal hernia, loculated sac full of adherent omentum. Hæmatoma discharged on the eighth day and continued to do so for five days. Left the nursing home in three weeks soundly healed. When seen in November the side operated on was, if anything, stronger than the side unaffected. He has now been passed for service abroad.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

A MEETING of the section was held on Feb. 8th, Mr. A. L. WHITEHEAD, the President of the section, occupying the chair.

Operation for Senile Cataract.

Mr. BASIL LANG read two papers on related subjects, the first entitled A Modification of the Usual Method of Removing the Lens in the Extraction of Senile Cataract and the second A Modification of the Usual Method of Needling the Lens Capsule after Cataract Extraction.

In the first of these contributions he referred to a case he was told of in which a tumour was seen in one eye, lying over the ciliary body, and this tumour was regarded as malignant. No lens could be seen behind the pupil. The eye was excised and section showed it to be the lens; it had apparently been forced into that position when an attempted extraction was done. He remarked that the lens did not always begin to come forwards on the first pressure of the cornea below. Though he had watched many operators, he had rarely seen the lens born without some coaxing, or aided by the cystotome. The first effect of placing the curette on the lower part of the cornea was to decrease the intra-ocular volume, and he went on to explain in detail what he considered happened, from the point of view of mechanics, at each stage in the operation. He thought it would be distinctly advantageous if the hole through which the lens was to be delivered could be made as deep as possible in the antero-posterior diameter; this was his modification of the customary technique. Having completed a large section he lacerated the capsule with the cystotome. With the patient looking down, he pressed the scoop flat on the sclera at the 12 o'clock position with its edge in contact with the wound, and he pressed it backwards towards the centre of the globe. The wound began to gape, and the vitreous forced the lens forwards against the under surface of the cornea. Further pressure increased this gaping, and the lens began to force the iris in front of it out of the wound. On further pressure the lens edge was seen to stretch the iris until it came close up to the pupillary border, and now for the first time Mr. Lang applied pressure below with the curette against the cornea. The iris was never subjected to pressure between the sclera and the lens, and apparently had not lost its tone, and the slightest touch with the repositor or the stream from the irrigator caused it to return within the eye, and the pupil assumed a central position. His modification, he submitted, rendered the operation both simple and safe. At Moorfields, before he adopted this modification, he had 5 prolapses in 43 straightforward simple extractions. He had given up using eserine drops. In the last 31 cases at the same hospital he had had only two prolapses, one of which should not be brought into the series as the iris of that was atrophic. By avoiding damage to the iris iritis did not follow the instillation of eserine. The iris did not lie flaccid and toneless in contact with the wound; rather it was taut, thus allowing any escaping aqueous to run over its surface.

In his paper on his modification for needling the lens capsule after cataract extraction, Mr. Lang said that after the lens had been removed and the eye was quiet, it was desirable to make a hole in the lens capsule, otherwise at a remote date the visual acuity would begin to be reduced. At that date the capsule would have lost its elasticity and the operation would be difficult as the incision would not gape and any flap cut would fall back into its original place and continue to occlude the pupillary area. The needling was intended for its remote benefit rather than its immediate. In former days eyes were lost from one of two reasons: sepsis, or glaucoma, due to the angle becoming blocked by vitreous, or by exudate from a chronic cyclitis, or from both causes. The sepsis resulted from the operation tract becoming infected with organisms from the conjunctival sac, and it could probably only occur if the needle was made to enter the anterior chamber by passing it directly through the cornea. To avoid this the needle should be passed subconjunctivally into the anterior chamber. To make more sure, the surface of the conjunctiva could be painted at the point of entry of the needle with a 1 per cent. solution of silver nitrate. Whenever vitreous got into the anterior chamber glaucoma was liable to occur. This was why dislocation of the lens occasionally ended so disastrously in glaucoma; for this reason he did not advise patients to have the lens removed in its capsule, as that left the vitreous unsupported. He was careful to procure a needle of suitable proportions; if the shaft of the needle was of the correct diameter it just filled the hole and prevented escape of aqueous. If the shaft diameter were 1 the width of the blade should be 1½. His habit was to use a Bowman's stopped needle, not a Ziegler's knife; moreover, it was rarer to find the latter with a shaft the correct size. The sooner the operation was done the easier it was. He never divided the capsule if there was any quantity of unabsorbed lens matter. In the latter event, when the eye was white, he passed the needle into the anterior chamber, rotating the shaft through 90°, moving the blade paddle-fashion to stir up any lens matter. He then had the eye hot bathed, and in a few days the lens matter had been absorbed. He described his procedure with a wealth of detail. He had the room darkened and good focal illumination to enable one to see the gossamer-like posterior capsule. With a needle of the correct proportions none of the aqueous would escape from the anterior chamber, and the capsule could be cut three or four times if necessary. He summed up the advantages of this modification as follows: It was easy, it avoided the possibility of sepsis, it obviated the possibility of glaucoma, and it eliminated the necessity of stirring up the vitreous.

Dr. W. H. BRAILEY emphasised the importance of tilting the lens forward while it was being extracted. In regard to needling, he agreed that the vitreous coming into the anterior chamber was the most common cause of the subsequent onset of glaucoma following cataract extraction. The worst cases of glaucoma were due to the ingrowing of corneal epithelium through the wound.

Sir RICHARD CRUISE said it was most important to produce in cataract extraction the tilting forward of the lens which Mr. Lang had spoken of. He described the technique which he had himself employed during the past 14 years. In that time he had had only three cases in which there was slight adhesion of the iris to the lip of the wound. In none of his cases had there been prolapse.

Mr. J. GRAY CLEGG said he would be reluctant to do discission in early stages; most of his cases returned with excellent acuity of vision without this having been resorted to.

Mr. T. HARRISON BUTLER spoke of the importance in his view, of avoiding all forms of pressure in the operation. He expressed himself as an advocate of Ziegler's method of operating and of his knife. When sepsis occurred in these cases he felt sure it often came from within, from material circulating in the blood stream.

Mr. H. KIRKPATRICK said that the modification described by Mr. Basil Lang was not so radical as that which had been carried out at Madras for ten years. He detailed his own method of procedure.

The PRESIDENT said he had now reverted to the combined operation, with which he was quite satisfied. Mr. Basil Lang's modification was very interesting and probably some members would try the preliminary pressure above before exerting the usual pressure from below.

Mr. LANG replied.

Classification of Diseases of the Choroid.

Mr. MALCOLM L. HEPBURN read a paper on this subject. He said the nomenclature in relation to diseases of the choroid had always, in his view, been unsatisfactory, and there seemed to be no settled opinion as to the ætiology and course of the disease processes attacking the choroid. Fundus diseases ought to be classified according to the structure in which they occurred. The results of classification by position alone were that the terms retino-choroiditis, myopic choroiditis, choroidal atrophy, degenerations, holes, &c., were applied indiscriminately to all sorts of diseases, regardless of their pathological meaning, or whether they originated in the choroid or the retina. In this paper he dealt with choroid only. All such conditions were associated with pigmentary disturbances, but in solely retinal affections no such changes occurred. The American "Encyclopædia of Ophthalmology" contained 26 forms of choroidal inflammation which seemed to require separate headings. The classification he now put forward fell into five groups: (1) inflammatory; (2) vascular; (3) degenerative; (4) congenital; (5) new growths. The need for discriminating between the first two groups was, that in the recent stage the treatment was quite different. At present the term retino-choroiditis was used to describe both acute and scarred forms, whereas it really implied an acute inflammation. The clinical features associated with inflammatory diseases of the choroid were vitreous opacities, and sometimes keratitic deposits in the acute stage, with scotomata in the usual field. The paper was illustrated by a number of drawings.

Mr. RAYNER D. BATTEN said that even after hearing Mr. Hepburn's paper he still claimed a special place in classification for diseases of the macula, which area was singled out, anatomically, physiologically, and clinically, from the rest of the fundus. Both choroid and retina showed special reactions to disease in the macular area. He based his claim chiefly on clinical grounds, instancing that the area was comparatively exempt from attacks of syphilitic and tuberculous disease. The greatest support for his contention was in the establishment of the maculo-cerebral group. He showed a large number of drawings by means of the epidiascope in elaboration of his views.

Exhibition of Cases and Specimens.

Mr. A. D. GRIFFITH showed a male with tuberculosis which had started in the optic nerve head. When the patient was first seen there was no vitreous effusion, and the mass was obviously arising from the nasal half of the optic disc and the immediately surrounding retina. Since that date it had passed nasally forwards into the vitreous, leaving a patch of apparently normal retina between the mass and the nerve. The man had had pulmonary tuberculosis. Wassermann was negative. He also showed a baby which was brought to the hospital four hours after birth, with the right eye luxated forwards out of the orbit. It was a forceps delivery on account of placenta prævia. There now seemed to be a weak attachment to the globe. The optic nerve showed simple atrophy; clearly it had been ruptured.

Miss ROSA FORD sent a case (shown by Mr. M. HINE) of ethmoidal mucocele in a woman. Three weeks ago, when first seen, she complained of her eyes hurting her and watering. She also had occasional momentary diplopia and a chronic discharge from the right side of the nose. When, at 6 years of age, she had scarlet fever, a lacrymal abscess on the right side was opened. At about the same date she had a chronic discharge from the left nostril. There was now a cystic swelling in the left orbit, extending above and below the internal tarsal ligament, and just above the latter there was a small and rather sharp prominence in the orbital margin. On extreme movement in any direction diplopia resulted. There were no fundus changes in the left eye, and the vision was 6/9. Mr. Gay French regarded it as an ethmoidal mucocele.—Mr. GRAY CLEGG spoke of a similar case and recommended that this be dealt with from the inside.—Mr. HARRISON BUTLER considered it might be a frontal sinus condition and that the case should be handed over to a rhinologist.—Mr. R. AFFLECK GREEVES also favoured the view that this was a frontal mucocele, as the ethmoidal cases he had seen pointed lower down.—Mr. R. LINDSAY REA said that to get a good skiagram in such a case as this it was necessary to use a hard tube, preferably one with a 12-inch spark-gap.—The PRESIDENT considered this mucocele fronto-ethmoidal in origin. He agreed it should be attacked from the interior, on the nasal side. It was clearly a case to be dealt with by the rhinologist. It should give a good result, with no scarring whatever.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A MEETING of the Federation was held on Feb. 12th at the Elizabeth Garrett Anderson Hospital, Miss M. CHADBURN, the President, being in the chair.

Dr. HELEN CHAMBERS read a paper on

The Progress of the Cancer Problem.

Dr. Chambers said she spoke with the object of arousing in the members of the Federation a sense of the importance of cancer research, and of the vast fields that yet remain to be conquered. It was her hope and belief that the Medical Women's Federation might, as a corporate body with a large available amount of clinical material, institute some scheme of research under which individual members' work might be directed, correlated, and unified, so as to yield more valuable results than might accrue from solitary effort. She spoke of research up to the present as falling under two main headings—namely, inquiry into causation (and prevention) and into treatment. With regard to the advance of knowledge in the last ten years or so, under the first heading we had undoubtedly come to recognise the important part played by chronic irritation, even though this was due to such dissimilar things as arsenic, petroleum, and parasites. The common factor appeared to be repeated death of cells in a localised area, and the inference might be that a breakdown product of such cells acted as a growth stimulant. Dr. Chambers dealt as examples with cancer of the mouth and pharynx in men and cancer of the cervix in women. She put forward also some suggestions as to the part played by skin parasites as irritants in cancer of the breast and Paget's disease of the nipple.

Under the heading of treatment, operations and irradiation by X rays and radium were discussed, and the possibility of the production of an antigen-immune body reaction was touched on. Dr. Chambers's remarks on the necessity of a thorough understanding of the principles of X ray dosage, and the danger of increasing the rate of tumour growth by ill-timed and insufficient treatment were stimulating. She pointed out the difference, often forgotten, between the experimental laboratory animal and the human patient, and from this point of view regarded immunisation of the cancer patient as still only in the realms of speculation. She insisted, however, on the importance of Coley's work, in spite of its empirical nature, and held out some hope of greater biochemical knowledge in the future.

Discussion.

Dr. EVA WHITE mentioned a paper by R. Knox, in which it was suggested that at only one period of its life was the malignant cell susceptible to the action of X rays. She wondered whether this, if true, would affect treatment. She also suggested vaginal ionisation as a prophylactic against cancer of the cervix.

Dr. LOUISA MARTINDALE said she had noticed that in cases where she had used X rays to produce atrophy of the ovaries, if an insufficient dose was used at

first, the subsequent effective dose had to be much larger than usual. She spoke briefly on the Erlangen treatment of inoperable cases.

It was proposed by Lady BRISCOE, and seconded by Dr. EVA WHITE, that a committee should be formed to draw up a plan of campaign with regard to the proposed part to be played by the Medical Women's Federation in cancer research, and Dr. Chambers, Miss Chadburn, Dr. Martindale, Lady Briscoe, and Lady Barrett were proposed and elected.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE annual meeting was held at Manchester on Jan. 18th, when Prof. A. DONALD (Manchester) was elected President for the ensuing year.

Exhibition of Cases and Specimens.

Dr. LEITH MURRAY (Liverpool) showed a para-vaginal lipoma weighing 17 oz. removed from a woman aged 25. On a mistaken diagnosis of "cold abscess" she had been treated on a spinal splint in a union infirmary for ten months, eventually being discharged as "improved." During this time a labour had been induced at 32 weeks in view of the obstruction caused by the "abscess." Soon after her discharge a swelling appeared in the inner side of the right buttock near the anus. This was the lower pole of an elongated, soft swelling which extended as high as the finger could reach and encroached on the vagina. The hip, spine, and sacro-iliac joints were all found normal and pelvic lipoma diagnosed. The specimen was easily removed in one mass through a 2½-inch incision over the swelling in the buttock, and proved to be a typical true lipoma, hour-glass in shape; the upper lobe, 3 in. long, was flattened, the isthmus, 1 in. by ¾ in., had been behind the pubic arch, and the lower lobe, 3½ in. long, was rounded.

Prof. BLAIR BELL (Liverpool) showed two specimens: (1) Sarcoma of the uterus removed from a single woman aged 61; the menopause had occurred at 50. For seven months there had been slight irregular bleeding from the uterus, which was enlarged; for the last month the bleeding had been almost constant and there had been a little pain. Pieces removed at an exploratory curettement on April 15th, 1923, showed the growth to be a spindle-celled sarcoma; panhysterectomy with removal of both appendages and the vermiform appendix on April 28th, 1923. (2) Cystic sarcoma of the left ovary. This occurred in a II.-para aged 55, ten years after the menopause. Slight abdominal pain had been present for six months. On Dec. 4th, 1923, there was dysuria followed by the sudden onset of severe abdominal pain. The attacks of pain varied in severity, gradually becoming more severe and causing vomiting. On examination there was slight abdominal distension; a hard mass, apparently rising out of the pelvis, was palpable in the left iliac fossa; there was a large cystic swelling in the pouch of Douglas pushing the uterus forward. On Dec. 17th panhysterectomy with removal of both appendages and appendicectomy; the solid portion of the ovary had to be separated from its adhesions to the brim of the pelvis and left iliac fossa. Section showed the solid portion to be a mixed celled sarcoma.

Dr. LEITH MURRAY and Prof. ERNEST GLYNN (Liverpool) showed a rare specimen of diffuse fibromyomatous overgrowth of the uterus. The patient, a woman aged 31, menstruated regularly since marriage a year and a half before; but she had experienced an abdominal swelling and pain "for some months." Complete hysterectomy was performed. The body of the enlarged uterus measured 6 in. long, 5½ in. broad, and 6 in. antero-posteriorly. It was uniformly studded with nodules of fibromyomatous overgrowth which formed irregular bosses under the peritoneum. The nodules were whorled and not encapsulated. The cervix was normal. The uterine cavity was considerably enlarged but the mucosa normal. Microscopical sections of seven pieces of the uterus showed an ordinary fibromyomata and no trace of adenomatous tissue. There were, however, several small groups of young and proliferating blood-vessels like those in a capillary nævus. The specimen resembled almost exactly one figured by Cullen and described as a "general myomatous tendency" of the uterus. It was suggested, however, by the exhibitors that the term "fibromyomatosis" was more in keeping with pathological usage. The ending osis was frequently employed to describe diffuse proliferation of a neoplastic type in various connective tissues—e.g., lipomatosis, fibromatosis, neurofibromatosis, myelomatosis. The pathology of the tumour was unexplained, but it was probably in some way associated with the vascular proliferation.

Dr. D. DOUGAL (Manchester) described a case of ovarian dermoid ruptured during labour and expelled per rectum a month after delivery. The patient was a primigravida, aged 28, medium pelvic contraction. She was admitted 48 hours after the onset of labour and after forceps failure at home. Easy extraction after perforation; the prolapse of anterior rectal wall noted at the time was ascribed to the previous forcible attempts at delivery. On the fourth day pyrexia, abdominal pain, distension, and vomiting; condition critical, temperature reaching 104° F.; after a fortnight a piece of bone was felt through an opening in the anterior rectal wall; a fortnight later a necrotic piece of the tumour including the plate of bone and dermoid process was passed per rectum. She was discharged two months after the labour and is now in good health.—Prof. H. BRIGGS suggested that the tumour might be a para-rectal and not an ovarian dermoid, and Dr. DOUGAL agreed.

Prof. GLYNN, recently assisted by Dr. Morris Cohen, summarised his observations on

Forty Autopsies upon Pulmonary or Cardiac Embolism

and upon primary pulmonary thrombosis. Almost invariably the lungs had been hardened and dissected, the various thrombi in them drawn and then examined microscopically. The main conclusions were: 1. Death usually occurs in either embolism or thrombosis in from 10 to 20 minutes. The development of primary thrombosis was often suggested by a slight rise in pulse-rate without a corresponding rise in temperature. 2. Primary pulmonary thrombosis was much more frequent; death occurs in post-operative cases about the tenth day. In 35 consecutive post mortems, 28 being on post-operative cases, 4 were due to embolism, 30 to primary pulmonary thrombosis, and 1 doubtful. In another case, primary thrombosis and embolism were combined.

The main evidence for primary thrombosis was: 1. The presence of proved ante-mortem thrombi, usually in both lungs and in all lobes, which could not possibly have developed in the few minutes elapsing between the acute onset and death. 2. The presence of age changes in the pulmonary thrombi, demonstrated by (*a*) hæmolysis; the blood pigment was deposited not only in the thrombi but often in the walls of the pulmonary arteries surrounding them, and even in the bronchial cartilages; and (*b*) commencing organisation of some thrombi which occurred in about a third of the cases.

The main causes of primary thrombosis were: 1. Mild sepsis, demonstrated by the frequent very slight pyrexia, and by the frequent occurrence of a non-hæmolytic streptococcus in the thrombi. 2. Pulmonary stasis, for the patients were invariably bedridden. The danger of the latter could be greatly diminished by encouraging patients to practise movements and deep breathing as soon as possible after operation. At the Liverpool Royal Infirmary from 1905 to 1915 there were 9 autopsies upon primary pulmonary thrombosis (post-operative) from the gynæcological ward, and 7 surgical (post-operative) and 3 medical from the rest of the hospital; from 1916–23 there were 2 (post-operative) from the

gynæcological ward, 6 surgical (post-operative), and 3 medical from the rest of the hospital. The diminution in the number of gynæcological cases coincided with the introduction by Prof. Blair Bell of systematic deep breathing and active arm exercise, practised every morning from the third or fourth day after the major operation. No such exercises were practised in the rest of the hospital.

CARDIFF MEDICAL SOCIETY.

A MEETING of this Society was held on Feb. 12th, Dr. R. CAMERON being in the chair.

Dr. E. COLSTON WILLIAMS read a paper on

The Relations of the Private Practitioner with the Public Health Services.

He contrasted three points of view: that of the general practitioner, who is engaged mainly in curative medicine and who views his work from an individualistic standpoint; the local authority that is required to perform duties in providing treatment with due regard to economy and efficiency; and the view of the medical officer of health, whose endeavour is to organise treatment services within the limits of expenditure allowed, and who must take a general view of the problem. In tracing the rapid change from the environmental standpoint of public health to the new preventive view, which deals with the individual from birth through infancy and childhood into adult life, he pointed out that a certain broadness of outlook and social interest was necessary in all those members of the profession who were in any way associated with modern preventive medicine, and now that there was growing unity throughout the profession, that still closer relations were possible between the practitioner and the organisation of preventive services in all forms. The cordial coöperation of the general practitioner in the tasks of prevention was essential for success. The ante-natal clinic, the school clinic, and the venereal disease clinic were unable to deal with more than a small fraction of the problems for which they were created, and competent private practice must bridge the gaps. If the Insurance Act was to attain its fullest usefulness, it must be by allowing the practitioner to work under such conditions as would enable him to give his best service, fully assisted by all possible scientific aids to diagnosis and treatment. Other points of importance dealt with were medical assistance rendered under the terms of the new Midwives Act, responsibility in the administration of isolation hospitals, the relation of the practitioner to the tuberculosis service, and what might be the desirable lines of evolution of the Public Health Laboratory. Many difficult problems in relation to voluntary hospitals were arising which the profession seemed somewhat loth to tackle—for example, what was to be the status and remuneration of staffs, whether work and payment for work for public authorities should be accepted, and, if so, what terms would be satisfactory to the profession?

Mr. J. BERRY HAYCRAFT gave a demonstration on

A Simple Method of Performing Blood Transfusion.

He pointed out the various indications, and emphasised the importance of employing a method that could be simply and rapidly performed, owing to the frequent urgency of these cases, and the fact that they had only occasionally to be dealt with. The operation was divided into two stages: (1) The selection of the donor. Two methods of performing the agglutination tests were described. If type II. and III. sera are not available, the direct action of the recipient's serum on the cells of the donor is tested. (2) The transfusion is performed using a 3·8 per cent. solution of sodium citrate as an anticoagulant. The donor's blood is received into a graduated jug containing the solution, and the transfusion performed with an ordinary saline infusion apparatus, the veins being cut down upon and glass cannulæ employed. The citrate solution was in two graduated flasks contained in drums which were sterilised, so that they could be kept indefinitely, and the whole apparatus was made in convenient portable form by Messrs. Staniforth of Cardiff. It was pointed out by this means transfusion could be employed anywhere, and it was not necessary to send patients long distances to a large hospital. In injuries to the limbs transfusion should be employed prior to operation, whereas in abdominal hæmorrhage laparotomy should be performed first, and the transfusion commenced immediately the hæmorrhage is controlled.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society on Feb. 26th, with Sir DAVID WALLACE, President, in the chair, Mr. DAVID LEES opened a discussion on

CONGENITAL SYPHILIS.

He began by sketching the historical facts regarding the hereditary transmission of syphilis, and went on to discuss the method of transmission of infection, concluding from his own experience that maternal syphilis was most commonly the cause, infection being by the placental route. With regard to Colles's law, he said that the blood of over 90 per cent. of the mothers exhibiting the apparent paradoxical immunity showed a positive Wassermann. Maternal syphilis had a more profound effect on heredity than paternal, and the virulence was more marked still when both parents were affected. The more recently infected the mother before conception the more virulent was the course of the disease in the child; the older the infection the less marked was the effect of parental transmission. Up to the eighth month of pregnancy the virus might be transmitted to the child in utero. Subsequent to this the infection was more probably acquired during its passage through the maternal passages at birth. The virulence of transmission lessened with time, and in the fifth and sixth year of untreated syphilis the infection might no longer be transmitted. Cases were quoted by Fournier, however, of transmission up to the twentieth year. Treatment had a profound effect in lessening the virulence of heredity, and active specific treatment of the mother during pregnancy could almost eliminate it.

Rietschel considered that the modified course of the disease in the mother was due to the uterus being an unsuitable medium for the spirochæte. This theory was supported by the experimental work of Neisser. More recently Routh had attributed the attenuation of the virus to spirillolysis set up by the chorionic ferments. While the spirochæte was subject to the influence of the ferments the syphilis was quiescent, and subsequent to pregnancy redeveloped and resumed its former activity. Toxic symptoms during pregnancy were more marked when the infection was acquired at or near conception. Congenital syphilis was generalised from the beginning, and consequently had a more profound effect on general nutrition, and so on mental and physical development.

Diagnosis.

In diagnosis, Mr. Lees said, careful inquiry into the possibility of acquired syphilis in both parents should be made, and as to a history of miscarriages on the part of the mother. The early history of other children and examination of them was often helpful. Spirochætes could be demonstrated in the serum expressed from the margin of active skin lesions. In spite of this, contagion from congenital syphilitic children was rare. The Wassermann test was positive in well over 90 per cent. of cases with active lesions, being practically 100 per cent. in cases showing gross lesions at birth. The provocative Wassermann was often useful in doubtful cases. Mr. Lees referred at some length to the luetic test, considering that it should only be employed as

supplementary to the Wassermann test. The so-called therapeutic tests should only be employed when more accurate methods had failed. Many non-specific skin lesions were benefited by arsenic and mercury.

Clinical diagnosis was discussed at length. Both in early and late congenital syphilis the lymph glands tended to be involved and super-added tuberculous infection was not uncommon. Iritis occurred early, and with it there was often an accompanying cyclitis. Interstitial keratitis, rare in infancy, was common from the eighth to the fifteenth year. Mr. Lees referred to the wide variations of the clinical picture, and said that in no pathological condition was it so important to avoid looking at the body in compartments. He referred to the predisposition to intercurrent lesions, and to the simulation of other conditions by congenital syphilis, stressing the importance of considering it as a possible ætiological factor in apparently intercurrent disease. He quoted Kolmer's maxim, "Always suspect syphilis, but be slow to diagnose it."

Prophylaxis and Treatment.

Discussing prophylaxis, Mr. Lees said that the first principle was the intensive treatment of all cases of acquired syphilis until a clean bill of health had been given to both parties. In the married prevention of conception must be insisted on until all clinical evidence of disease had disappeared. If conception had already taken place intensive treatment of both parents, and especially of the wife, was essential. It should be instigated early and continued to a week before term. Arsenic was the most potent drug, and was usually well tolerated by the pregnant woman. Any of the "914" preparations might be given. Joint exhibition of arsenic and mercury in pregnancy might produce excessive strain on the already burdened kidney. The drugs should, therefore, be given separately. Neo-natal treatment in all cases should be begun at the earliest possible moment within a few hours of birth. Mr. Lees recommended "dribble" doses of the arsenical drug daily or on alternate days as the safest and most satisfactory method. The intravenous route was preferable for rapidity of effect in the first or second dose, but subsequently intramuscular sulpharsenol was most satisfactory. When the gross lesions had disappeared mercurial therapy was commenced in conjunction with sulpharsenol. Bismuth had recently been used in congenital syphilis with good effects. Increase of body-weight was the most useful criterion of success after the gross lesions had disappeared. The minimum period of treatment was two years, and it could not be any less in any case of congenital syphilis, no matter how slight. In many others much longer periods were essential, according to the reaction of the patient to the therapy exhibited.

Discussion.

The PRESIDENT drew attention to the importance of clinical symptoms in diagnosis.

Dr. LEONARD FINDLAY, of Glasgow, who was present as the guest of Dr. John Thomson, gave an interesting account of his experience of congenital syphilis at the Ruchill Fever Hospital. He considered that the incidence had been grossly exaggerated. He believed that Fildes's figure of 0·5 per cent. of children in hospital classes was probably about correct. He showed several slides, giving statistics supporting his views. He believed strongly in the Wassermann test.

Prof. B. P. WATSON discussed the Wassermann test in new-born children, and pointed out how the presence of Wharton's jelly in cord blood rendered fallacious the results of the test.

Dr. J. V. PATERSON said that he now scarcely considered it necessary to do the Wassermann test, which he regarded as most reliable, in cases of interstitial keratitis. He had been very chary of salvarsan in the early days, but now used it always with benefit.

Dr. J. S. FRASER said that in his experience congenital syphilitic ear disease was not benefited by arsenical therapy.

Prof. G. M. ROBERTSON said that he had been struck lately by a feature of both interstitial keratitis and general paralysis of the insane—namely, the delay in their appearance in the course of the disease—and suggested anaphylaxis as a possible explanation. He asked whether there was not a natural tendency to cure in untreated syphilis.

Dr. J. H. GIBBS showed some lantern-slides illustrating Moon's molars with the typical doming of the cusp.

Mr. SCOT SKIRVING asked if there had ever been discovered any difference, culturally or otherwise, between the spirochæte of congenital and acquired syphilis.

Mr. C. W. MACGILLIVRAY spoke of cases in the pre-Wassermann days which had apparently recovered with purely symptomatic treatment.

Colonel GLEN LISTON spoke of the sigma test, and said that in a large series of cases he had found 29 per cent. negative Wassermanns positive to that test.

Mr. LEES replied to the various points.

Dr. R. CRANSTON LOW then showed a case of urticaria pigmentosa of 30 years' duration, and Mr. W. J. STUART one of facio-hypoglossal anastomosis.

MANCHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on Feb. 6th, Dr. E. M. BROCKBANK, the President, being in the chair.

Dr. G. J. LANGLEY read a paper on the

Treatment of Auricular Fibrillation.

He first dealt with the necessity for an appreciation of the functional pathology of the condition. With regard to the different methods of treatment, the aim of the digitalis treatment was to produce heart-block, whilst the aim of quinidine treatment was to terminate auricular circus movement. Dr. Langley dealt with the ordinary method of digitalis administration and Eggleston's massive digitalis method. An analysis of the results of 50 cases treated by digitalis given by the ordinary method was discussed. With regard to the literature of quinidine treatment 1006 cases had been already collected, and now 441 further cases were added, with the results and dosage. Twenty-three cases that had been treated and the results obtained were described.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee 19 cases were considered and £226 voted to 17 applicants. The following is a summary of the new cases relieved:—

L.R.C.P. & S. Edin., aged 61, who practised in Bristol. Applicant broke down in health four years ago, necessitating several severe surgical operations from time to time. He can only manage part-time assistantships or light locum work. Voted £26 in 12 monthly instalments.

Daughter, aged 53, of F.R.C.S. Edin. who practised in Birmingham. Applicant is one of 12 children, her father died when she was 18, and her mother six years ago. The mother's income was an annuity. Applicant has been crippled with neuritis and unable to work for three years. Now slowly improving, but the light work she is able to manage is not sufficiently remunerative to live upon. Her income last year amounted to £45. Voted £12 in 12 monthly instalments.

Widow, aged 37, of L.R.C.P. Edin. who practised in Wales and Canada and died at sea in November, 1923, on the return journey from Canada. The practice was the only source of income, and applicant is left with four children, ages 6 to 16 years, and the estate is not expected to realise more than £100 per annum. Applicant asks for educational assistance. Committee made a small grant to render applicant eligible for the Guild to investigate the case.

Three children, aged 9 to 14 years, of M.B. Aberd. who practised in Leeds and died in 1915. The mother married again, and has now lost her second husband, who was a metallurgist, before he was able to make any provision for her or his step-children. The mother asks the Fund to help with education. The children have £5 per annum each from the grandfather's estate. The Committee made a small grant so that the Guild will be able to investigate this case.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., M.S. at 11, Chandos-street, Cavendish-square, London, W 1.

Reviews and Notices of Books.

PHYSIOTHERAPY TECHNIC.

A Manual of Applied Physics. By C. M. SAMPSON, M.D., formerly of the Physiotherapy Service, Walter Reed U.S. Army General Hospital, Washington, D.C. London: Henry Kimpton. 1923. Pp. 443. 30s.

THIS book has been written in order to indicate the therapeutic value of various physical forms of treatment—viz., high frequency and diathermy, static electricity, actinotherapy, X rays (for non-malignant conditions); galvanic, faradic, and sinusoidal currents; massage and hydrotherapy. The largest sections of the book deal with diathermy, ultra-violet radiation, static electricity, and X rays. Shorter sections deal with the other physiotherapeutic agents, and there are special chapters devoted to the treatment by physical means of arthritis, locomotor ataxy, genito-urinary diseases, and hay fever. The book is dedicated to the "therapeutic peptimist," whom the author describes as the optimist who envisions much better things than are even now possible, and has the determination, courage, ability, and energy to go out and make his visions come true. The "peptimist" is the antithesis of the therapeutic nihilist.

The author has evidently had considerable experience of the subject on which he writes. He says that practically each step in every technique given in the book is based upon laboratory and clinical research, and that the results have been checked by others, who were by no means prejudiced in favour of the methods. He insists on the necessity of correct technique, and frequently emphasises his descriptions with instances in which the failure to pay attention to detail has resulted in the depreciation of the value of physiotherapy. For the application of diathermy the author describes a sedative and a stimulating method. In the latter only the gentlest degree of heat is applied, and the method is employed for the stimulation of the growth of sluggish tissues as, for example, in the treatment of ununited fractures. He speaks highly of diathermy for the treatment of paralysis due to nerve injury, and says that surgeons have often called attention to the fact that adhesions are much less firm and more easily removed in cases which had been subjected, before operation, to courses of diathermy.

The book is amusing to read in many parts. When speaking of the inability of the shocks from the static machine to do harm, the author describes how he discovered an arthritic mouse among a colony, and proceeded to give it the regular static treatment for arthritis. Its improvement was manifest from the time the first spark hit it, and during the 12 days of subsequent observation it covered more mileage, ate more food, and generally was more lively than any of the untreated controls. Certain statements are open to criticism. It is difficult to see how a heavy condenser discharge (preceded by heat) can "break up and squeeze out into the dilated blood and lymph spaces the semi-organised and organising inflammatory exudate." The graphic record of the sinusoidal current is incorrectly figured and described.

The book contains much useful information, and the results described should stimulate other workers to try the author's methods. A form of treatment for hay fever is said by the author to "come near being specific. It consists first in the application of high frequency; second, in the application of ultra-violet rays to the anterior nares; third, in the application of the same rays to the posterior nares and naso-pharynx." The volume is well prepared and fully illustrated. There are some useful diagrams, but many of the illustrations are pictures of patients receiving treatment, and these add to the bulk of the book without contributing much to its value.

DIABETES.

New Views on Diabetes Mellitus. By P. J. CAMMIDGE, M.D. Lond., and H. A. H. HOWARD, B.Sc. Lond. Oxford Medical Publications. London: Humphrey Milford. 1923. With 85 figures. Pp. 611. 21s.

THE authors here set out in book form much of the work which they have published during the last few years in current medical journals. The opening chapter deals with normal carbohydrate metabolism and the shape of the blood-sugar curve after a dose of sugar or a mixed meal, the maximum point being placed after the third hour unless the patient has a hyperchlorhydria. This experience differs from that of many observers who find the maximum point at the end of half an hour or very little later. The authors have attempted to show that the acid secreted in the gastric juice affects the curve by producing changes in the acid-base metabolism of the blood and liver; these experiments are not convincing.

The experiments which deal with the source of the amylolytic ferment in the blood stand on a different plane; the hypothesis seems to be proved that this ferment is formed in the liver and not in the pancreas though the latter organ controls its output. The effects of prolonged boiling on oatmeal and of long toasting of bread have been investigated, and the conversion of a certain proportion of the starch into dextrin is demonstrated. The authors are able to confirm Pavy's observation that dextrin is used in a different way from starch. The experiments on the amylolytic ferment and the increase in the amount of sugar in the blood after hydrolysis (called the difference value) have been used by the authors to sort out the different types of diabetes. One-third of the patients show changes which resemble those which occurred in the dog whose pancreas had been partly removed; one-third show changes which resemble those seen in a rabbit whose liver has been damaged; while the remaining third show changes which are not characteristic of either group and may be due to a combination of the two causes. This evidence is opposed to the views of Allen and others who believe that the pancreas is primarily involved.

In the chapter on the principles of treatment 34 pages are devoted to the treatment with insulin. From internal evidence it seems that this represents only the early observations of the authors, and no reference is made to work published after May, 1923. Experiments made on two severe cases of diabetes are described and the results compared with Mackenzie Wallis's unstandardised extract. In one case only did this extract cause a definite fall in the blood-sugar, while insulin always caused a fall, unless much carbohydrate was given, and a corresponding improvement in the clinical condition. In one case insulin was discontinued, as no further improvement seemed to be occurring, although great improvement had taken place, and the boy died some two months later. The authors express the view that to give two injections a day to a boy of 14 for the rest of his life is a somewhat appalling prospect. They hesitate to accept the view that insulin stands in the same relation to diabetes mellitus as thyroid extract does to myxœdema. "for the pancreatic factor is not present or dominant in every case of diabetes as a deficiency of the thyroid is in myxœdema." The statement that in some respects the action of insulin is more akin to the relief of pain by a dose of morphia, is remarkable in the light of the work of other observers in Canada, the United States, and this country. With regard to the principles of dietetic treatment the authors also stand in opposition to modern views, since they do not hesitate to give much larger amounts of carbohydrate than are usually given and their fat ration is very low. If the patient can be kept sugar-free so much the better, but if not they think that it is better for him to pass sugar than to have the carbohydrate ration reduced too much. The authors' work on the effect of atropine and morphia on the shape of the

blood-sugar curve is interesting; they think that some patients can be helped in this way.

The book represents an enormous amount of laborious work. It contains many diagrams which make the text more easy to understand and a good list of references at the end of each chapter will be useful to other workers. The fact that some of the views expressed are at variance with those of other workers justifies their collection within the covers of a single volume.

The Treatment of Diabetes Mellitus. With Observations Based upon 3000 Cases. Third edition. By ELLIOTT P. JOSLIN, M.D. Harvard, Clinical Professor of Medicine, Harvard Medical School; Consulting Physician, Boston City Hospital. London: Henry Kimpton. 1924. Pp. 784. 36*s*.

IN the third edition of his well-known book Prof. Joslin has added a new section on insulin, his attitude towards which is contained in the words: "Insulin does not cure diabetes, but it is a priceless gift to the severe diabetic provided that he be intelligent and faithful." The section opens with a history of the discovery of insulin by Banting and Best, and of the work of numerous others who showed that extracts of pancreas had an effect on the metabolism of sugar, or who were at all events very near the discovery. This makes very interesting reading. The next 60 pages give the results of insulin treatment for one complete year, starting from August, 1922. These have been uniformly good apart from some definite cause, usually the fault of the patient or the intercurrence of other disease. The treatment is very carefully explained; minute details are given as to the best way of keeping the syringe and performing the injection.

"It is a mercy," writes Prof. Joslin, "that at present insulin becomes inert when given by mouth and that its present use is restricted by syringe," explaining this strong statement on the ground that insulin is a most potent remedy from which untold damage might occur if it was used indiscriminately. In one respect the author has changed his standpoint, since he now says that it is important to keep not only the urine sugar-free but also to keep the blood-sugar normal. He thinks that patients should not gain weight unduly. During this first year 20 died out of a total of 293 insulin-treated patients. In only five is the cause of death given as coma and one of these was complicated by tuberculosis; some of the others were admitted in the late stages of coma; the remaining 15 all died of intercurrent affections.

No mention is made of any work on insulin done in England, although several papers were published before August of last year and this omission is apparent throughout the whole book. English workers on this showing would seem to have contributed nothing to the advance of our knowledge. The remainder of the book follows the lines of previous editions; the pages on incidence and ætiology are full of interesting information. A statement by Sherrill is quoted with approval, "that functional deterioration in diabetes can be traced to definite causes, particularly infectious and dietary excesses, that downward progress clinically depends upon the different susceptibilities of different patients to these injurious influences, and that by strict avoidance of such influences downward progress can be largely or wholly avoided." The section on pathology is hardly worthy of the rest of the book. Renal glycosuria is dismissed in two pages. Dietetic treatment is adequately dealt with in 140 pages, considerable space being given to the desirable relationship between protein, fat, and sugar. A section entitled, "What every patient should know," is very clear and well devised; 28 pages devoted to the composition of foods will be very useful to the physician who is called to answer the sensible questions of intelligent patients.

Prof. Joslin's book is packed with interesting information about diabetes and is well written. It is so readable that the author may be forgiven for being at times too discursive.

THE OFFICIAL HISTORY OF AUSTRALIA IN THE WAR, 1914–1918.

Vol. XII. Photographic Record of the War. Sydney: Angus and Robertson. 1923. Pp. x.-753 and Index. 28*s*.

THE photographs reproduced in this volume were taken by the Australian official photographers, Capts. G. H. Wilkins, *M.C.*, and J. F. Hurley; Lieuts. H. F. Baldwin and J. P. Campbell and others, while the preface and annotations are supplied by Mr. C. E. W. Bean and Mr. H. S. Gullett. It aims at supplying a complete authentic pictorial narrative of the effort of Australia in the war, and although the begetters of the work do not say whether their aim has been fulfilled or no, we ourselves may affirm that the book is of extraordinary interest. We have pictures of scenes in Australia on the outbreak of war, of the starting of the troops, of the Royal Australian Navy and the Mercantile Marine, and of the raising of the Australian Imperial Force. Plates 15–19 give views of the *Sydney—Emden* fight, the last one being a picture of the sorely-battered *Emden* after surrender. In the rest of the book we have pictures from all other fronts. An inspection of Plates 219–231 or 267 and 268 should make clear the anxiety of France to obtain reparations. Plates 219 and 220 show a clean comfortable little village street, while Plate 221 shows a series of rubble heaps, but it is the same place. Many photographs were taken in the Palestine operations, all of which are of much interest, one very notable one being 627, the Jordan Valley from the air. Altogether the volume is in every way a worthy companion for its narrative fellows.

MIND AND HEREDITY.

By VERNON L. KELLOGG. Princeton: University Press. 1923. Pp. 108. 7*s*.

"MIND" is possessed by all animals—possibly plants too. The instinctive and most elaborate reactions of insects show no obvious signs of being subject to what we should call intelligence, but some of the lower animals—rabbits, for example—give unmistakable evidence of having, in a small degree, the capacity for thought and choice which some people have supposed to be man's prerogative. The instinct mind is wholly inherited and owes nothing to environment. A great deal, at any rate, of the human mind is inherited too, and it is certainly not in mental capacity that all men were created equal. Environment has its share in education, but educational systems overlook too much the predominant differences in natural intelligence. Such in outline is the substance of these pleasant lectures, which will stimulate the reader to think rather than tell him what to believe.

INTERNATIONAL CLINICS.

A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles. Vol. III. Thirty-third Series. London and Philadelphia: J. B. Lippincott Co. 1923. Pp. 312. 42*s*.

WE take occasion to remind readers of this serial potpourri of medicine and surgery, edited by Dr. Henry W. Cattell, with the collaboration of numerous specialists. Sections of this publication are devoted to (1) diagnosis and treatment, (2) morbid psychology, (3) pædiatrics, (4) medicine, (5) surgery, and (6) the medico-legal aspect of death by hanging, and the present series contains altogether two dozen papers. The titles of some of these show what a wide field has been covered. The first paper is on the Treatment of Allergic Diseases, by W. Storm van Leeuwen, of Leiden; some way down the list there is a paper on What Can and What Can Not be Done to Prevent Falling of the Hair; in another paper arguments are adduced to show that cancer is never a purely local disease; another deals with thyroid therapeutics. In the pædiatric section the interesting problem of *Bacillus coli* infection in childhood is dealt with. Volumes of this kind are hardly suitable for medical students,

but for the reader who is more free to choose his literature such a work has many attractions. The editor has picked his staff with an eye not only to their knowledge, but also to their capacity for passing it on to others in a digestible form. The pictorial style when handled skilfully may be a valuable aid to memory. In his paper on Thyroid Therapeutics Dr. William N. Berkeley writes: "When thyroid is properly given, I have seen half a dozen teeth sprout in a backward baby's mouth in three weeks' time, like tulip bulbs in warm spring weather." Touches such as this brighten a medical work.

COMMON SYMPTOMS OF AN UNSOUND MIND.

A Guide for General Practitioners. By G. RUTHERFORD JEFFREY, M.D. Glasg., F.R.C.P. Edin., Medical Superintendent, Bootham Park Mental Hospital, York. With a foreword by Sir JAMES CRICHTON-BROWNE, M.D. Edin., F.R.S. London: H. K. Lewis and Co., Ltd. 1923. 7*s.* 6*d.*

Dr. Jeffrey has performed a considerable service to the profession in publishing his short manual on the common symptoms of mental disorder. He deals exclusively with the external features of mental disease; each common symptom is considered in the light of its possible significance. A chapter is devoted to each of five main groups, delusions, disorders of perception, disorders of conduct, excitement and depression, and confusion. The discussion of their significance in relation to the other factors of a given case is illuminating and readable, and is illustrated by vivid accounts of many actual cases. Among these the reader will be puzzled to find no less than three ladies who were 61 years of age, two of them with cerebral tumours, described on adjoining pages. Dr. Jeffrey has strong views on the question of legal responsibility, and a chapter is devoted to this subject. The only missing feature is a discussion of the indications for certification, and of measures necessary and feasible when certification is delayed or impracticable. Such a chapter would add to the usefulness of a book which will in any case prove of great value to the general practitioner.

PRACTICAL ANALYSIS OF BLOOD.

Second edition. By VICTOR CARYL MEYERS, M.A., Ph.D., Professor and Director of the Department of Biochemistry, New York Post-Graduate Medical School and Hospital. London: Henry Kimpton. 1924. Pp. 232. 25*s.*

IT is difficult nowadays to realise that the first clinical estimation of any blood constituent was introduced by Bang as recently as 1913, and that the science of clinical blood analysis really started at this date. Previous to this period the methods in use required such enormous quantities of blood that they were quite impossible clinically.

The volume under consideration is already well known as one of the standard works on the subject, and is used extensively in America. Unfortunately English clinicians are only just beginning to realise the importance of blood analysis, hence the demand for such a work is not so great in this country. The book is extremely well arranged, and the illustrations are numerous and good. A very wide choice of methods is given, and the author has modestly refrained from emphasising his own particular techniques. There are, however, several points to be noted. First, we would ask, Why do writers copy mistakes and misprints (and they are very great) when describing Folin's and Wu's methods? The perpetuation of these errors leads workers who try the methods to condemn them, whilst in reality the Folin system is undoubtedly excellent. A second point is that the reader does not obtain a clear appreciation of the clinical value of the results of the analyses he has been told to perform. The information is more of a technical than a medical type, with the result that the vast practical value of the determinations is lost sight of. A pleasing thing is the chapter on blood uric acid, and most especially, the detailed description of Sir Alfred Garrod's monumental work on the subject nearly 75 years ago. It is, indeed, a pleasure to find a modern text-book which brings such names to the fore as A. B. Garrod and Carl Schmidt, the famous professor of physiological chemistry at Dorpat.

On the whole, the book is very good, and it is to be hoped that it will have a large circulation in England, and that workers over here will take to heart the doctrines that the author so eloquently pleads.

JOURNALS.

BRITISH JOURNAL OF SURGERY.—The January number contains the eleventh of Sir D'Arcy Power's series of Eponyms, Bell's Palsy.—John Fraser's contribution to the discussion on Operation Shock at the sixth meeting of the International Society of Surgery is reproduced in full. He reviews the theories held up to the end of 1915, and discusses the result of war researches upon this subject, and finally comes to some interesting conclusions. There follows an account of the discussion on the subject.—J. J. Levin and A. Porter report four cases of intestinal obstruction due to an accumulation of large numbers of *Ascaris lumbricoides*.—J. Fraser and N. M. Dott record their experimental results in a new method of performing aseptic intestinal anastomosis. The detail of technique, which is new, is their method of dividing the occluding ligatures on the cut ends of the gut by a special instrument which they call their ligature guillotine.—Sir Arthur Keith, in his eleventh Mitchell Banks memorial lecture, deals with the origin and nature of hernia. He describes the factors which may produce sacs of developmental origin, and also the mechanism whereby sacs may be acquired in later life.—H. J. Waring and H. E. Griffiths, in reporting 15 cases of acute pancreatitis, analyse the symptomatology, diagnosis, pathology, and treatment of this condition.—R. Hamilton Russell describes his special method of obtaining extension in cases of fractured femur. His main contention is that some flexion of the knee is essential to correct alignment, and he maintains that his method gives not only good results but much comfort to the patient.—R. J. Gladstone and C. P. G. Wakeley analyse the relative frequency of the various positions of the vermiform appendix, judged from 3000 examinations.—P. Sargent brings forward some points in the surgery of the pituitary gland. He reports his cases and describes his operative methods, which are based on Frazier's original operation.—Naughton Dunn and F. W. Stuart record two cases in which the tensor fasciæ femoris muscle has been used as a transplant in cases of paralysis of the quadriceps muscle.—H. Platt and W. R. Bristow publish an exhaustive paper on the remote results of operations for injuries of the peripheral nerves. They conclude that end-to-end suture alone holds out good promise, and even with this method at least 20 per cent. failures are to be expected. Certain nerves are dealt with separately and their percentage recovery given.—This paper, being a contribution to the discussion on that subject at the International Society of Surgery, is followed by a critical summary of the discussion.—D. P. D. Wilkie reports a case of paralytic ileus treated by a high and a low enterostomy. The drainage from the upper jejunal tube was so profuse as to prejudice the result from loss of body fluids. The two tubes were therefore joined up outside the abdomen, and the bowels were opened naturally. The two fistulæ closed rapidly when the tubes were removed.—An account is given of a visit to the Professor Thorkild Rovsing and the Rigshospital at Copenhagen.—The following rare or obscure cases are recorded: (1) G. Hadfield, malignant papilloma of the renal pelvis associated with calculus; (2) D. Wood and C. S. Gideon, two cases of fatal hæmatemesis after splenectomy for Banti's disease; (3) C. J. Marshall, perforation of the stomach by a needle, being one of many metallic foreign bodies present in that organ; (4) T. Twistington Higgins, subacute pancreatitis occurring in association with acute intestinal obstruction in a new-born infant.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

VIII.—STARTING A PANEL PRACTICE.

BY LEONARD SHOETEN SACK,
OF THE MIDDLE TEMPLE, BARRISTER-AT-LAW; JOINT AUTHOR OF "MEDICAL INSURANCE PRACTICE."*

"Men are everything; measures are comparatively nothing."

MUCH can be said either for or against any system of compulsory health insurance controlled by the State, and there is still greater scope for argument when considering the particular system which was established in this country in 1911 under the National Health Insurance Act. With the merits or demerits of that system we are not here concerned. For the purpose of our present subject it is sufficient to stress the fact that there are to-day more than 15 million people in this country who are compulsorily insured, and who, with few exceptions, seek and obtain their medical attendance and treatment only from panel medical officers.

This figure would, by itself, indicate that the treatment of insured persons is a matter which the average doctor about to start in general practice cannot afford to disregard. But the influence of national insurance extends farther. The normal family does not employ two medical men. Even in these days of revolutionary tendencies, the "family doctor" remains a very real and popular conception. There may be only one insured person in a family of four or five, yet the "panel doctor" who is chosen to look after him will almost invariably be sought when the non-insured members fall ill. Whether for good or for evil, the doctor who is starting in practice will, with rare exceptions, be virtually compelled to choose between undertaking insurance practice or being satisfied with a greatly restricted private practice. It is not surprising, therefore, that there are more than 15,000 panel doctors in the British Isles, and that this number is increasing.

Preliminary Steps.

In the administration of medical benefit under the National Insurance Acts the controlling authority does not, as in the case of most other public health services, select the doctors by whom the service is to be carried out. Every qualified medical practitioner—that is to say, every doctor whose name appears on the Medical Register—is entitled as of right to treat insured persons. Moreover, the insurance practice cannot be terminated without the consent of the doctor except for some very grave offence, and then only after a special inquiry by the Minister of Health.

The method of entering insurance practice is simple. For the purpose of administering medical benefit, public bodies, known as insurance committees, are set up for each county and for the larger county boroughs. The members of these committees represent insured persons, doctors, chemists, and the local council. One of the obvious duties of the committee is to arrange for the necessary supply of doctors, and for this purpose it keeps a list of the names and addresses of the local practitioners who have undertaken to treat insured persons. This is the "panel"—officially known as the Medical List. A doctor undertaking insurance practice must first secure that his name is included on this list. To do this it is necessary only to send to the clerk of the insurance committee (whose address can be obtained from any post office) a notice in the following form.

FORM OF APPLICATION FOR ADMISSION TO MEDICAL LIST, NATIONAL HEALTH INSURANCE.

I, A. B., residing at ....., a duly qualified medical practitioner registered in the Medical Register in that name, and having the following medical qualifications, namely, ..., desire to undertake the medical attendance and treatment of insured persons in the area of the Committee upon the terms for the time being in operation in that area, and for this purpose I hereby accept service under those terms and apply for admission to the medical list of the Committee.

The district or districts within which I undertake to visit insured patients and particulars of my surgery hours are given below:—

District.	Surgery.	Days and Hours of Attendance.

Signed .....

Date .....

On receipt of this notice by the insurance committee, the doctor's name (assuming that it does, in fact, appear on the Medical Register) must be entered on the Medical List for the district, and the doctor *ipso facto* becomes entitled to treat the insured persons who apply to him. In practice, the clerk to the committee informs the doctor that his name has been placed on the list, and also furnishes him with a supply of the many forms which appear still to be inseparable from any State-controlled service—e.g., certificates, record cards, and prescription forms.

Conditions of Service.

Concurrently with the doctor's right to treat insured persons, there necessarily arise the duties and obligations which form part of the doctor's agreement with the committee. Before 1920 the doctor signed a contract which specified many of these obligations. Now there is no written form of contract, but the contractual relationship remains. It will be observed that the notice states that the doctor desires to treat insured persons "upon the terms for the time being in operation." These terms are mainly set out in the Medical Benefit Regulations, 1924. So far as the provisions of those regulations affect his insurance practice, the doctor is bound by them—they form part of his "contract." The part of the regulations most directly affecting the doctor (Schedule I., which includes the "Terms of Service" and the Medical Certification Rules) is issued by the insurance committee as a separate document. There are also two schemes prepared by the committee, one, known as the Allocation Scheme, applies the general requirements of the regulations on such matters as the provision of emergency treatment and the limitation of panel lists; the other—the Distribution Scheme—deals chiefly with remuneration.

It should be understood that when a doctor notifies the insurance committee that he wishes to treat insured persons, he thereby accepts the terms of service set out in the regulations and in the two schemes. He should, therefore, obtain copies of these documents from the insurance committee and should inform himself of their provisions before sending in his formal notice.

Duties Required.

It does not fall within the scope of this article to deal in any detail with the various obligations of the insurance practitioner. The principal services which the doctor undertakes to give to insurance patients may, however, be summarised in general terms as follows:—

1. The provision of general practitioner treatment to all insured persons on his list (excluding treatment in respect of confinements or attendance at miscarriages, but including the administration of anæsthetics or the provision of an anæsthetist).
2. The provision of emergency treatment to any insured person whose doctor is not, at the time, available.
3. The writing of prescriptions for necessary medicines and certain appliances on a special prescription form (in some cases the doctor must himself supply the medicines or appliances, at an additional rate of payment).
4. The issue of certificates. In all, there are five certificates of incapacity, one death certificate, and one voluntary certificate.
5. The keeping of records in respect of the diseases and treatment of all his insurance patients.

* A Work of Reference to the Medical Benefit Provisions of the National Health Insurance Acts. By R. W. Harris and L. Shoeten Sack. London: The Scientific Press, Ltd. 1922. Pp. 327. Price 7*s.* 6*d.*

The doctor undertakes to visit any patient whose condition requires it, and to provide proper and sufficient surgery accommodation for those patients who are well enough to attend at the surgery.

The insured person, on his side, is bound by certain rules which, inter alia, require him to obey the instructions of his doctor, not to make unreasonable demands upon his professional services, and not to summon him during the night except in cases of serious emergency.

Payment and Goodwill.

Except in Manchester and Salford, where an attendance system prevails, payment for insurance practice is made on the capitation basis. The Court of Inquiry recently appointed by the Minister has fixed the capitation fee for 1924 at 9*s*., and has recommended that this fee should continue until the end of 1927. It should be understood that under the capitation system of payment the Central Fund from which all payments are made is constituted by multiplying the capitation fee of 9*s*. by an estimated number of insured persons in the country. The Central Fund is then distributed among the insurance committees according to the number of insured persons calculated to be in each area by reference to the local committee's register. As the local registers do not provide a true count of the number of insured persons actually in the area at any given time, the doctor will not necessarily receive an amount exactly equivalent to the sum of the capitation fee multiplied by the number of insured persons on his list. Payment is made quarterly. Generally speaking, a doctor is not permitted to accept any fee from an insurance patient.

In addition the flat rate per head of insured persons on the doctor's list, there are certain special payments—e.g., in respect of anæsthetists' services and the treatment of temporary residents. Where a doctor is required himself to supply drugs and appliances, he receives an additional payment of 2*s*. a head, with special payment for certain expensive drugs and appliances, such as vaccines, insulin, &c. Doctors in rural areas also receive a "mileage allowance" where the patient resides more than two miles away, or where the country presents special difficulties of travel.

In considering the income to be derived from panel practice it must be remembered that, except under very special conditions, a doctor in single-handed practice is not allowed to have more than 2500 insured persons on his list. If assistants are employed he may be permitted to have an additional number, not exceeding 1500 for each assistant. Partners must not have more than an average of 2500, although any one partner may have up to 3000.

Goodwill in an insurance practice has never been officially recognised, although the principles are now largely the same as with private practice. A doctor buying a practice which includes a panel of insured persons cannot, of course, buy the right to treat all the insured persons who were on his predecessor's list, for every insured person is now able to change his doctor at any time. The regulations do, however, provide that the doctor who withdraws from the Medical List of an area may require the insurance committee to notify his insurance patients that his successor is willing to accept them on his list, and the incoming doctor receives for a limited period extra payment in respect of this undertaking to accept any of his predecessor's patients.

The Controlling Authorities.

The general relationship of the insurance doctor to the various bodies concerned in the administration of medical benefit can be indicated only briefly. The approved societies, as such, have no control. They are concerned primarily with the payment of cash benefits, and they may therefore be brought into contact with the doctor on questions of certification of incapacity; but not even on such matters have they any power directly to control the doctor's work. Indirectly, however, the societies, as representing insured persons, nominate three-fifths of the members of the insurance committee. The insurance committee is the body which deals with the practical administration of medical benefit. It is with this committee that the doctor enters into his agreement; and it is this body which will, in the first instance, investigate any complaints made by or against him. The committee also distributes the remuneration. Even this committee cannot, however, alter the doctor's terms of service without the express consent of the Minister of Health.

On all important matters the Minister of Health determines the conditions of insurance practice; and it is with him that the Insurance Acts Committee of the British Medical Association hold the consultations which, in practice, have always preceded any material alteration in the terms of service. The doctor has a right of appeal to the Minister from any disciplinary decision of the insurance committee; only the Minister can alter the rate of remuneration or inflict a pecuniary penalty. The Minister has appointed regional medical officers throughout the country. In addition to their specific duties as referees, these officers are in a position to offer general advice and guidance, and it is to the advantage of a doctor entering into insurance practice to become acquainted with the regional officer for his district.

Finally, there is in each area a panel committee which is a body directly representative of insurance doctors. All the members are doctors and three-fourths are panel doctors. It may be said, generally, that the panel committee must be consulted by the insurance committee on all matters (e.g., the alteration in the terms of service) which materially affect the insurance doctor. The panel committee is also a body which can be consulted by the individual doctor on any matter of doubt, more particularly when the opinion of the profession rather than the official view is desired.

ALLOWANCE FOR SUBSCRIPTIONS IN ASSESSMENT FOR INCOME-TAX.

THE question of allowance of subscriptions to medical societies and periodicals is one which often arises, and we have received the following letter on the subject from a correspondent:—

"SIR,—Can you refer me to a regulation or a definite ruling to the effect that medical men are entitled to deduct, when making returns of their income for assessment of income-tax, the expenses incurred by subscribing to medical societies and periodicals? I am employed whole time by the Ministry of Pensions for a definite salary; two or three years ago, after a long discussion, I succeeded in persuading the Inspector of Taxes for this district that I was entitled to allowances for such expenses on the ground that a medical man must keep his professional knowledge up-to-date, and the deductions were accordingly allowed for two or three years. The Inspector of Taxes has, however, now written to me as follows:—

"'With regard to your claim for allowance of the expense of subscribing to certain periodicals and professional associations, I have referred to previous returns and correspondence, but I do not find any evidence that the purchase of the periodicals in question, or membership of the associations, is an indispensable condition of the continuance of your office or employment under the Ministry of Pensions. If such is the case, and evidence is available, will you kindly let me have it? In its absence I consider that the allowances made in the past were not properly due, and I shall be quite unable to continue them.'

"The suggestion seems to be that as I am in Government employ it is not necessary for me to keep my knowledge up-to-date."

Where the question of allowance of subscriptions to medical societies and periodicals occurs in connexion with a practice there is no difficulty, for the assessment is then under Schedule D, one of the rules of which provides for a deduction of expenses "wholly or exclusively laid out for the purposes" of the profession. Where, however, the assessment is in respect of employment, and therefore under Schedule E, the Inspectors of Taxes usually object to allow such subscriptions on the ground that they are not provided

for in the rule requiring the expenditure of "money wholly, exclusively, and necessarily in the performance" of the duties. It has been urged in a similar case that a professional position requires professional qualifications, that such qualifications necessitate membership of professional societies, and that such membership involves the payment of annual fees for subscriptions and periodicals. The ruling, however, by the Board of Inland Revenue was that, in their opinion, the expenses in question did not fall within the provisions of Rule 9 (as to expenses), and that a deduction was, therefore, not admissible. It will be seen, then, that whilst the subscriptions are usually allowed to the man in actual practice, such a subscription is not allowed where a salaried position is being filled. In the latter case it is considered that unless the conditions of the agreement embody the requirement to belong to a society, the subscription thereto cannot be considered to be "wholly, exclusively, and necessarily" expended.

There is justification for the medical associations to urge that, where a professional qualification is required in the fulfilment of an appointment, the annual fee in connexion therewith should be allowed, and it would be well to take a test case to the Special Commissioners on the point.

Reports and Analytical Records.

"VULCAN" ELIXIR.

(MESSRS. MORSON AND SONS, 47, GRAY'S INN-ROAD, LONDON.)

THIS preparation—supplied in the form of a liquid—is intended as a tonic and as a general stimulant for the nervous, muscular, and digestive system. It is stated to contain lecithin, cerealin (wheat phosphates), papyotin (vegetable pepsin), nux vomica, milk-sugar, and the accompanying mineral constituents, potash, lime, iron, &c. The chemical examination shows total extractives (solid matter) 38 per cent., water 62 per cent., and the presence of milk-sugar, iron, lime, and phosphates, and, in general, substantiates the composition as set out by the manufacturers. The elixir contains no alcohol, it possesses an agreeable flavour, and constitutes a useful addition to this class of tonic. The presence of papyotin should serve to supplement the protein-dissolving enzymes in the gastric and pancreatic secretions in cases where diagnosis indicates a deficiency of these in the patient.

(1) CARDIBAINE; (2) DIGIBAINE.

(ANGLO-FRENCH DRUG COMPANY, LTD., 238A, GRAY'S INN-ROAD, LONDON, W.C. 1.)

We have received from this firm samples of these cardiac tonics of which the former is crystallised strophanthin, called Ouabaine in France, and the latter is a combination of the former with digitalin. Ouabaine is strophanthin prepared from *Strophanthus gratus* in a state which the pharmacologists have taken care should be one of perfect purity from the collection of the seeds, which is carefully supervised, to the last stage in preparation. Of the recognised use of strophanthus as a cardiac tonic and diuretic nothing need be said here. Cardibaine is administered orally and intravenously, but a warning is issued against intramuscular injection as dangerous and even impracticable. The intravenous method is used when rapid results are required as in acute dilatation of the heart. The drug is supplied in ampoules containing ¼ mg. for intravenous use, and in solution for use by the mouth, when the dose is from 15 to 30 drops twice or thrice daily according to a physician's prescription. Digibaine, the combination of Ouabaine with digitalis, which is indicated in cardiac conditions where digitalis is ordinarily employed, has been found of value by French physicians, who have tried it in prolonged tonic cardiac treatment, for valvular conditions with lack of compensation and cardiac insufficiency. This drug is also supplied for oral and intravenous use.

ALLONAL.

(HOFFMANN-LA ROCHE CHEMICAL WORKS, LTD., 7 AND 8, IDOL-LANE, LONDON, E.C. 3.)

The full name of this preparation showing its composition is allyl-isopropyl-barbituric acid with phenyl-dimethyl-amino-pyrazolon. It is put forward as a hypnotic and analgesic which can be employed as a substitute for morphine as it seems to have no habit-forming propensities. Numerous clinical reports have been published in the American medical press, but the drug is new to the English market. American experience goes to support the claims of the manufacturers that allonal is a remedy of real value for controlling insomnia and pain. As the preparation contains a derivative of barbituric acid it comes within the scope of the Poisons Schedule and is only supplied to registered practitioners and pharmacists.

MERCUROCHROME.

(W. HARRISON MARTINDALE, 10, NEW CAVENDISH-STREET, LONDON, W. 1.)

Mercurochrome "220" has a chemical composition—dibromo-oxy-mercury fluorescein, or its sodium salt. The compound contains over 20 per cent. of mercury, but, as a vesical antiseptic in a 1 per cent. aqueous solution, can be tolerated by the bladder for one to three hours without occasioning pain. It has been referred to in medical literature as being rapid in effect as an antiseptic in cystitis and pyelitis; it has also been used in gonorrhœa, chancroids, and as a dressing for buboes. We have here a preparation which acts as its chemical composition would lead us to anticipate. It is supplied in 10-g. bottles at the price of 13*s.*, but a 1 per cent. solution ready for use as an antiseptic bladder injection is sold in 4-oz. bottles, price 3*s.*

SANTOPERONIN—A NEW ANTHELMINTIC.

(ORBIS WORKS, LTD., BRUNSWICK; MATTHEWS AND WILSON, LTD., COLE-STREET, LONDON, S.E. 1.)

The very high price of santonin at the present time has stimulated the demand for an effective substitute as a therapeutic agent in the treatment of intestinal parasites such as thread-worms and round worms. A preparation that has recently been submitted to us for this purpose is santoperonin, which is claimed to be extremely effective against the foregoing parasites and also against tape-worms, which of course are very resistant to santonin. Santoperonin is a reddish-brown powder, insoluble in water, and containing copper in combination with an organic substance the constitution of which is somewhat indefinitely described as being a derivative of phenol and a lactone derived from naphthalene, and bearing in Germany the name of santoveronin. Santonin itself is a lactone derived from naphthalene, but also contains a ketonic group, and recently it has been shown that the active principle of male fern is a phenolic compound, and in santoperonin an attempt has been made to combine the therapeutic effect of these two substances and also the anthelmintic properties of copper. The sample submitted to us contained sulphate, but otherwise appeared to agree with the maker's description. Although insoluble in water, santoperonin is decomposed by dilute mineral acids with liberation of the corresponding copper salts, and therefore acids and acid foods should be avoided when it is used, and it is also advisable to administer it in conjunction with magnesia to prevent it from being attacked by the gastric acids. The use of calomel or of phenolphthalein with santoperonin is also contra-indicated.

The dose of santoperonin is 0·03 g. for adults, and 0·01 to 0·02 g. for children, two to three times daily. It is free from the horrible taste of male fern, and appears to be agreeable to take. Its use is stated to be free from danger, an accidental overdose merely producing vomiting with ejection of the drug. Eulogistic clinical reports are given by Wolfheim (*Der Landarzt*, Nov. 1st, 1923). In view of the small doses required and its lower cost, it should prove more economical than santonin in the treatment of round worms and thread-worms, and it may possibly prove superior to pelletierine tannate in the treatment of tape-worms.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 23, 1924.

THE CAMPAIGN AGAINST CANCER.

A WISE distribution of any moneys entrusted to the British Empire Cancer Campaign is now assured. The Scientific Committee appointed to advise on the administration of the funds collected by the British Red Cross Society for the campaign consists of the following distinguished members: Sir JOHN BLAND-SUTTON, Dr. H. H. DALE, F.R.S., Sir RICHARD GARTON, Prof. F. GOWLAND HOPKINS, F.R.S., Dr. ROBERT KNOX, Sir WILLIAM LEISHMAN, F.R.S., Prof. C. J. MARTIN, F.R.S., Prof. ROBERT MUIR, F.R.S., and Sir HUMPHRY ROLLESTON. It is stated—not very exactly—that half of this number have been selected jointly by the Medical Research Council and the Royal Society. The general aims of the campaign are set out in modest language in the manifesto, and are worthy of public support. No extravagant promises are made, but it is pointed out that more money means more research workers and better facilities for their work, that investigations can be pushed in fields as yet untouched, that variations in cancer incidence in different parts of our own country and abroad may be explained, and that dissemination of the knowledge thus acquired must help towards success against one of the most dreaded scourges that afflict mankind. In the nine months since the campaign was first started £70,000 have been collected, and though it is hoped ultimately to obtain a much greater sum, the Scientific Committee is to be called upon to apply the money already received without delay. Its specific functions will be to devise schemes of research and to advise and report upon questions relating thereto, including the allotment and application of funds. The Committee will also be closely concerned in maintaining communication between workers all over the world, in making their results and discoveries mutually available, and in keeping the public informed of the nature of the problems to be solved, and the progress made towards their solution.

In wishing good speed to a movement which is now proceeding under such happy auspices, we would add one more to the messages that have been sent to subscribers, actual and potential. We have already hinted that they must be prepared to pay the piper without calling the tune. This will be the less irksome, since the untrained sympathiser is for the most part not able to distinguish between the tunes. And workers in laboratories dedicated to research on cancer or any allied problem cannot be marshalled and organised like an army; they serve not one but many kings, and are as careless of the etiquette of the battle as are members of foreign legions. But one thing must not be forgotten: they are not merely mercenaries. They will coöperate gladly as individuals, but at a hint of autocratic control they disappear from the field, to fight the problems of another disease in their own way, with their own weapons. Thus coöperation cannot be enforced; neither can overlapping be prevented until we have an official audit of the results of research—a prospect far enough off at present. The only guarantee that any new weapon has been well planned and forged is that others can use it with as good effect as its inventor. The contrast between the immense literature on insulin which has arisen since 1921 and the comparative silence that has followed other apparently important discoveries announced within recent years is significant. The speed with which a crowd of workers appears at the centre of a new and hopeful discovery is like the rush to a reputed gold mine. Claims are staked out, lines of communication are established; if there is no gold after all, the crowd soon fades away. But when the existence of a mine is proven, one man cannot work it alone. The success of Japanese workers in producing cancer in mice by painting with tar stimulated investigators in many different laboratories throughout the world to try this method, and the result of this overlapping has been to create a new era of research in which the Japanese technique is the beginning, not the end, of experimentation.

One point remains to emphasise in fairness to those who have already devoted their lives to cancer research. The absence of knowledge as to the cause or the cure of cancer has misled many into thinking that little is known of this disease. And yet, just because there is no parasite to distract the attention of workers from the bodily lesions, or because experimental production of these lesions has till recently been impossible, it is actually the case that the descriptive pathology of cancer is more developed and better known than that of almost any other disease. Classifications in terms of malignancy, of embryonic tissue of origin, of distribution, of histological appearances, are numerous and are all justified; early symptoms and signs are defined; and treatment, both operative and palliative, has been worked out in detail. All this information has been laboriously collected and recorded for a long term of years. Even now more is known about the pathology of cancer than about the pathology of diabetes mellitus. It may need but the touch of some magic wand to transform this enormous pumpkin into a coach which will drive us to complete enlightenment. Let us hope that the British Empire Cancer Campaign will prove the fairy godmother.

CHILDREN AND YOUNG PERSONS.

WE noticed last week certain prominent aspects of the Children, Young Persons, &c., Bill, which has just been published as a document of 150 pages containing 200 clauses, many of whose provisions, as we said, will command the universal approval without which the Bill cannot become law. The document should be read by medical men, who will see in the bold proposals evidence of a new spirit of social and domestic reform, quickened undoubtedly by the growing influence of the women's vote.

If the Bill is examined in order to compare its wording with the law as it stands to-day, we find that, quite apart from the sweeping changes of principle, the minor details manifest a progressive amplification. Gaps are closed; the old scales of penalties are made steeper, and the old precautions and protections are strengthened. Examples of this process are furnished by the clauses dealing with prevention of cruelty. The present offence of failing to provide "adequate food, clothing, medical aid, or lodging" (under Section 12 of the 1908 Act) reappears in the Bill as failure to provide "sufficient and proper food and clothing, or sufficient lodging, or any requisite medical or surgical treatment." Neglect causing injury to health already covers mental derangement; the Bill adds also "any loss or diminution of mental power." Another familiar section of the Children Act of 1908 penalises a person who, going to bed under the

influence of drink, suffocates an infant under 3 years of age lying in the same bed. The new Bill enlarges "bed" to include couch, sofa, or chair, and "drink" to include drugs; it raises the age limit from 3 to 7, and extends the offence to persons who take drink after going to bed. Little points like these show that the draftsman has been directed to leave no loopholes, and medical evidence of many deplorable inquests has furnished the arguments on which the stiffening procedures have been based. Naturally the elaboration manifests itself in varying degrees of importance. The Act of 1908 forbids juvenile smoking, and allows a constable or park-keeper to confiscate the cigarettes of a person apparently under the age of 16, and to "search any boy so found smoking, but not a girl." Here was a gap to be stopped, and so the new Bill adds a proviso that girls too may be searched by women constables and women park-keepers, though we wonder if girls of 14 and 15 smoke in the parks to this significant extent. A more valuable innovation occurs over the removal of children from the custody of a convicted parent or from an otherwise undesirable home and their commitment to the care of some "fit person." These last two words are to cover any society or body corporate, existing or future, established for the reception and protection of poor children or for the prevention of cruelty to children. If such "fit person" can satisfy the magistrates that the child is a lunatic or defective, or a confirmed epileptic, or a sufferer from cancer or tuberculosis, or that its earning capacity is affected by impaired powers of sight, hearing, or speech, the commitment order can be extended in duration till the child comes of age.

Legislation along these detailed lines will hardly arouse controversy, except upon the lines ever open to the disputant that penalties are being suggested in directions where convictions will be difficult. Nor will the revision of the enactments about industrial and reformatory schools—a topic excluded from the scope of the consolidating Education Act of 1921—endanger the prospects of the Bill, nor the clause which seeks to prohibit the printing or publishing of the name or address of any child or young person charged with any offence short of murder or serious assault. There is, however, no disguising the fact that the Bill contains controversial elements. Anyone who recalls the delays and modifications imposed upon the Bishop of London's 1914 Bill before it emerged as the Criminal Law Amendment Act of 1922 will remember the sharp conflict over proposals to raise the age of consent. Similar hostility probably awaits the present proposal to abolish the defence, in certain cases of criminal assault, that the accused reasonably believed the girl to be 16, while it may be remarked that this defence will, it seems, still be open to a priest who is liable to two years' hard labour if he celebrates the marriage of a girl under 16. The new proposals for compulsorily clearing the court in certain cases will invite the comment that only two years ago it was found desirable to cancel the 1908 provisions for trying incest cases in camera. Criticism may also fasten upon the fact that in a Bill which in general purports to limit the criminal liability of children and young persons there appear to be some marked extensions of that liability. The 1908 sections which penalise the suffocation of infants in bed and the exposure of children under 7 to the danger of being burnt or scalded at an unprotected fire-grate apply only to offenders who are 16 years of age; the new Bill omits this age limit. Finally, some critics may think it unnecessary to provide that a boy of 14 or 15 must not be sentenced to be whipped, while a boy of 12 or 13 may still be whipped upon summary conviction. These points, however, if they be matters for disapproval, affect legal and judicial rather than medical opinion.

Bills which merely consolidate existing law are often blessed with a smooth and rapid passage through Parliament. The new Children Bill both consolidates and amends, and the amendments are frequent and substantial. If it should not at once attain the success for which its advocates are hoping, it will nevertheless be of value as a comprehensive statement of social policy upon which civic attention can usefully be focused.

RADIUM THERAPY.

WE have learned to look to the annual reports issued from the Radium Institute not only for a clear account of the year's work but also for an instalment of the serial story of radium therapy. The report for 1923, just issued, brings no disappointment, for 15 of its 30 pages are devoted to remarks on radium therapy in diseases of the thyroid, thymus, spleen, and lymphatic system, corresponding to the discussion last year of the uses of radium in diseases of the alimentary canal, and the description of its application to gynæcological conditions in 1921. The general account of the year's work, with a table of cases seen for the first time in 1923, is compressed into seven pages, while a summary by Dr. J. C. MOTTRAM of the five papers published from the research department during the year, and a technical report of the work under the charge of Mr. W. S. S. ALTON in the chemical and physiological laboratories, complete the report.

Mr. A. E. HAYWARD PINCH, the director of the Institute, notes that the provision of a limited number of bedrooms for the reception of in-patients has proved of great value. The available accommodation is always in demand and its early extension is announced. The programme outlined for occupying the patient between the four periods of exposure into which prolonged gamma radiation is divided shows a consideration for his comfort rare in institutions; the hours of treatment and rest are so disposed that the patient's normal habits of life are but little disturbed. The policy of declining to treat operable cases of malignant disease, other than rodent ulcer, has been rigidly adhered to, except when the patient has definitely objected to operation. This steadfast refusal to substitute for an established method, with definite and permanent cures to its credit, one which is still on trial must confirm the respect in which the Institute is held by the profession in general, and especially by surgeons. Indeed, the coöperation of surgeons has recently been sought with greater frequency, in order to provide the most convenient and effective access of the radium tube to the growth. The treatment of laryngeal tumours by subhyoid pharyngotomy, and of carcinoma of the cardiac end of the œsophagus by radium through a gastrotomy opening offer examples of a combined technique which is likely to develop still further in the future. The value of the combination of diathermy with radium is also insisted on, especially in the relief of carcinoma of the tongue and mouth. The general trend of radium therapy, other than that of abdominal viscera, is in the direction of increase of dose, the systemic disturbance caused by a large dose being transient. Radiation of the abdominal cavity, however, must be less concentrated, since the goblet cells of the intestine are peculiarly susceptible to gamma rays and when damaged are liable to infection

from the canal. Mr. HAYWARD PINCH seeks again to dispel the prejudice against radon—the name recommended by an international committee to replace the clumsy "radium emanation"—among practitioners. The therapeutic effect of radon and radium salt is stated to be identical; that the former gradually loses its potency, whereas the latter retains it almost indefinitely, is no real disadvantage, since the rate of decay does not vary and can be calculated in advance. The advantage of borrowing a highly compressible gas of no intrinsic value in a small tube rather than of an applicator containing some hundreds of milligrammes of a most expensive salt, with all the attendant risks, should be obvious. Advice is freely given to practitioners on treatment with radon apparatus, and where precise information of the nature and extent of the disease or growth is furnished full instructions as to technique and exposure will accompany the apparatus lent.

It will be seen that much useful information is given in small space. The least enlightening sections of the report are the tables; these comprise only a classification of patients who were seen for the first time between Jan. 1st, 1923, and Dec. 31st, 1923. The statistics as regards malignant disease of an institution where none but inoperable cases are treated could certainly not make encouraging reading if supplied over a term of years, and even those of certain medical diseases would probably be depressing. Great interest, however, would attach to the present condition of patients first examined before January, 1923, of whom we are told nothing, except that many of them were still under treatment during the past year. The difficulties of following up cases are admitted, and we do not suggest that special efforts should be made to keep in touch with old patients where this would entail trouble and expense that could not fairly be incurred. But since it is claimed that radium increases the duration as well as the comfort of life for certain incurable patients, an additional table chronicling the present condition at least of all who are still in attendance would be welcome. The only other criticism to be made refers to the headings under which cases are classified. The column headings common to both tables are as follows:—Table I. having an additional column differentiating the diseases treated: examined but not treated (31), recent report not received (127), received prophylactic radiation only (25), apparently cured (137), cured (93), improved (328), not improved (94), abandoned treatment (10), died (23). The absence of information as to the period regarded as recent—the whole period under consideration is only one year—prevents full estimation of the value of the other details supplied. In pleading for a revision next year of the way in which the tables are compiled, the hope is shewn that the undoubted value of radium therapy may receive more general recognition and that especially in certain otherwise intractable medical diseases it may be given a trial. There is set out on p. 409 an account taken from the report of the beneficial effect of radium in diseases of certain glands and of the lymphatic system. Of the five cases of lymphadenoma first seen during 1923, three showed improvement after treatment and one was apparently cured, whereas of each form of leucocythæmia four cases were treated and two showed improvement. A closer coöperation between surgeons and those undertaking radium therapy has now been secured; it remains for physicians to take fuller advantage of such hopeful signs as are available that this agent has at least the power of postponing death in certain dangerous diseases of the blood.

AFTER-CARE FOR THE TUBERCULOUS.

> "Teaching Chinese to a Negro, infusing a Latin-American with a Puritanical outlook on life, or inducing statesmanship in a politician, are problems equal in toughness to finding a suitable job for a tuberculous person, and keeping that person in that job."

So difficult is the problem of after-care in tuberculosis, in the words of Mr. J. BYRON DEACON, director of the New York Tuberculosis Association. In this country the solution of the problem looks more hopeful in the light of two public announcements. The Minister of Health decided that the time had come for removing the present restrictions on grants for the development of the tuberculosis service, and at the same time the Minister of Pensions issued instructions designed to secure the coöperation of all local agencies in the after-care of ex-Service men suffering from tuberculosis. Everything possible is to be done to assist these men to obtain employment in a suitable occupation, but it is desirable to be frank about the difficulties. Pensioners now receiving sanatorium treatment are for the most part either cases of chronic advanced tuberculosis or of chronic bronchitis with quiescent (or only suspected) tuberculosis. The former are unfit for work; the latter, being very dependent on climatic conditions, are not satisfactory from the employers' point of view. Many pensioners have been idle for so long that recommencement of work is difficult, mentally and physically; if they do not give satisfaction in the first few days they are liable to be discharged. The objection of employers to a tuberculous employee has fourfold origin: (1) His efficiency is, almost invariably, considerably less than that of the average worker; (2) customers and fellow-workers object to one who coughs, or has scars or deformity resulting from a surgical operation; (3) any case of tuberculosis occurring among fellow-workers will be ascribed to the patient, even should he be actually non-infectious; (4) some moral obligation is felt to help an employee who has a temporary or permanent relapse. Special facilities for pensioners at the employment exchanges must, therefore, be supplemented by arrangements and personal interviews with employers, and by general education of the public. It is difficult for the tuberculosis officer, overwhelmed as he is with clerical and other non-clinical work, to find time for this, but every such officer who is worth his salt has already worked on the lines suggested by the Minister of Pensions. Industrial workshops on the model of Dr. C. F. PEDLEY'S "graded factory" (THE LANCET, Feb. 16th, p. 369) are well worth a trial, although here again there are serious hindrances, the chief of which are: (1) To conduct such a business without serious financial loss, (2) to avoid conflict with trade-unions over questions of wages, (3) to find a market for goods, which may require preliminary disinfection.

In a recently published book,[1] with the title, "How Shall I be Saved from Consumption?" Dr. HENRY A. ELLIS gives much useful advice to the potential consumptive. He calculates that £1 spent judiciously on after-care is worth £3 spent on the dispensary, and £1 spent on the dispensary is as fruitful in good results as £6 spent on a sanatorium. This is also the chief lesson now being taught by the New York Tuberculosis Association. In its *Bulletin* for November and December, 1923, Mr. DEACON puts the matter graphically in the following words:—

> "Picture a fine foot-bridge built across a swamp, but left uncompleted just a few spans short of solid ground, thus obliging those who use it to step off and wade through the bog to cover the last lap to firm earth . . . just short of landing the consumptive on the solid ground of social and industrial readjustment. Six millions of dollars are expended each year for the maintenance and treatment of the tuberculous of New York City, in hospitals and

[1] How Shall I be Saved from Consumption? By Henry A. Ellis, B.A., M.B., Ch.B., assistant physician to the Margaret Street Hospital for Consumption, London. London: George Allen and Unwin, Ltd. 1923. Pp. 190. 6s.

sanatoria. An additional 5 per cent. expended on after-care would complete the bridge."

The same author calculates that about one-half of all the tuberculous in New York may be classed as permanently disabled, unfit to work full time all the time. He assumes that New York City has 20,280 tuberculous wage-earners or housekeepers, half of whom require help, supervision, and after-care. Realising their needs, the New York Tuberculosis Association has decided to organise a "vocational and placement service," the duties of which are to discover suitable occupations for persons with quiescent or arrested tuberculosis. Since research is an important part of this service, accurate and detailed records are kept by the staff, which consists of an executive, a medical consultant, two "placement" secretaries, a medical social worker, and a clerk-stenographer. A grant of money from the Laura Spelman Rockefeller Memorial has assured the continuance of this interesting experiment for three years, in the course of which it is hoped that a significant demonstration will be made. Meanwhile it is instructive to study the balance-sheet of the New York Tuberculosis Association published in the same number of its *Bulletin*. Of the $187,754.42 spent for the year ending Oct. 31st, 1923, nearly 20 per cent. was spent on training in health workshops men who were recovering from tuberculosis. Another 4 per cent. was spent on finding suitable employment for men and women on the road to recovery from tuberculosis. Health education (lectures, posters, newspapers, &c.) absorbed 28 per cent., and other health information work 9 per cent. Health work among children (holidays in the country, dental hygiene, &c.) absorbed 12 per cent. Research work has required 8 per cent. and general administration 9 per cent. The most striking feature of this balance-sheet is its disclosure of the fact that the New York Tuberculosis Association is attacking the problem at its two ends, and is hardly even nibbling at what is commonly regarded as the centre of the problem. More than 50 per cent. of the Association's funds are spent in research, education, and prevention, and almost a quarter is spent on after-care. There can be little doubt that the three-year experiment on after-care, to which we have just referred, will show that the New York Tuberculosis Association has been well advised in devoting so much of its finances to this hitherto much neglected section of the anti-tuberculosis campaign.

IN HONOUR OF DR. BRACKENBURY.

THE desire to recognise the eminent services to his profession of Dr. H. P. Brackenbury will find, we are sure, very general expression in all medical circles. An influentially signed letter in our correspondence columns calls attention to his brilliant work in presenting the case of the insurance practitioner before the recent Court of Inquiry. At one point in this inquiry the chairman of the Court so far lost official self-control as to say how fortunate the medical profession should count itself in having such an able and persuasive advocate as Dr. Brackenbury. He added, amidst laughter, "We shall have to steel our hearts against being unduly influenced by his pleadings." He did not add that although in the past Dr. Brackenbury may on occasion have been nettled by his friends, he has never been known to lose his urbanity in the presence of opponents. The first dinner in his honour was given by the London Panel Committee during a period of sharp internal criticism of the Insurance Acts Committee, and the warmth of feeling then shown proved not only very welcome to him, as the chairman of that committee, but was evidence of the confidence in his knowledge and advocacy felt by his professional colleagues. On a subsequent occasion Dr. Brackenbury himself stated that he wanted no better reward than the loyalty and sympathy of his colleagues. That reward he may rest assured of possessing.

Annotations.

"Ne quid nimis."

INFECTION BY PUBLIC TELEPHONE.

THE possibility of transmitting infectious disease through the use of public telephones is one that naturally concerns health officers, and the Postmaster-General has recently issued a press notice asserting that there is no real risk in the use of telephones in public call offices, and that the alarm raised from time to time has no foundation in fact. It may be useful to set out briefly the medical opinions on which this assertion is based. In 1905 Dr. William Collingridge, then medical officer of health for the City of London, caused some bacteriological experiments to be carried out in conjunction with the National Telephone Company for the purpose of ascertaining whether call office telephones, if used by persons suffering from contagious or infectious diseases, were likely to be a source of danger to the public. Prof. E. E. Klein, who carried out the investigation at St. Bartholomew's Hospital, reported that the results confirmed a previous inquiry by the City medical officer of health, and proved that there was no risk of infection. As a result of growing public interest Mr. Herbert Samuel in 1910 gave instructions that a number of telephones fitted in call offices in London, which had been in use for various periods of time and had received no special cleansing treatment other than that normally given to telephones of the kind, should be examined by an expert bacteriologist. The mouth-pieces were chosen from call offices at railway termini, post offices, meat markets, and other places of general resort, and were forwarded to Dr. H. R. D. Spitta at St. George's Hospital. In addition, Dr. Spitta was also furnished with a mouth-piece which had been used by a tuberculous patient, and with others from the Tidworth Sub-Post Office which had been used by consumptives from the South Brent Sanatorium. Dr. Spitta reported that his experiments had confirmed in every respect the results obtained by Prof. Klein six years before. The mouth-pieces examined were free from tubercle and diphtheria bacilli, and no other organisms pathogenic to guinea-pigs were present. It was thought desirable, however, to conduct a further series of experiments with telephones which had been used solely by tuberculous patients, and arrangements were accordingly made to fit telephones in the Frimley Sanatorium for the use of the consumptives there. These telephones were kept in use for periods ranging from seven days to four weeks and were then forwarded for examination. In February, 1912, Dr. Spitta submitted a second report to the effect that this further series of experiments was entirely negative in its results, and that with the data thus afforded, and in view of the results of his former experiments, he was of opinion that the transmission of tuberculosis through the medium of the telephone mouth-piece was practically impossible. These results were borne out by an independent inquiry initiated by the American Government. The Postmaster-General alluded in his press notice to the routine precautions that are taken to ensure this measure of safety. The call offices are cleaned and the transmitter mouth-pieces and receiver caps disinfected at intervals of about three days. The cleaning of public call offices situated in residential flats, shops, and other private premises is undertaken by the tenants of the premises, while the cleaning of call stations in post offices is carried out under the supervision of the postmaster.

TETRAGENUS SEPTICÆMIA.

ACCORDING to Mlle. Raissa Falk-Trotsky,[1] of Petrograd, who records three cases in her Paris thesis, two of which are original, *M. tetragenus*, which is a saprophyte of the skin and nasopharynx, is

[1] Thèse de Paris, 1923, No. 285.

capable of becoming virulent and giving rise to septicæmia. This form of septicæmia usually develops in association with other micro-organisms, especially the tubercle bacillus. Two forms of tetragenus septicæmia have been described—viz., a mild form characterised by fever, gastro-intestinal disturbance, and transient pleuro-pulmonary symptoms lasting from three or four days to about a week, and a malignant form, characterised by multiple lesions, deep-seated and subcutaneous suppuration, intense toxæmia, prolonged duration, and frequent relapses. The diagnosis of tetragenus septicæmia is impossible apart from an epidemic, but considerable diagnostic importance is to be attached to the hectic character of the fever, the multiplicity of the lesions, the absence of any important symptoms such as enlargement of the spleen, when the condition simulates typhoid fever, or of laryngo-bronchial catarrh in cases resembling influenza, and the frequency of remissions and relapses. An exact diagnosis, however, can only be established by direct examination of the pus, blood cultures, and serum agglutination. The immediate prognosis is relatively good, even in the severest forms, but the remote prognosis should be guarded owing to the frequency with which tuberculosis develops. The use of auto-vaccines is the best method of treatment. A bibliography of recent literature is appended to the thesis.

PRIMITIVE PATIENTS.

"WHAT a mean fellow you are!" said a Congo chief to the Rev. W. H. Bentley, who had cured the native of an illness and had come to inquire after his health. "What a fuss you made! I had to eat a fowl and feed well; what strange things you white men are! Why did not you give me a present when you left? What a mean fellow you are!" This passage is cited from Prof Lévy-Bruhl's "Primitive Mentality," a work of which one of the most interesting chapters is headed The Primitive's Attitude to European Remedies. Here are set down numerous instances of the curious demeanour of Central Africans, natives of New Guinea, Battaks, Basutos, Melanesians, and South American Indians towards the medical men, lay and missionary, who have helped them. When cured of a large and loathsome ulcer, for instance, they expect a solatium from their benefactors. Nor can they understand why the demand of a present appears illogical to the white doctors. Prof. Lévy-Bruhl explains the attitude of the native in a manner at once surprising and convincing. The native, in the first place, is not aware that the medical man has taken any real trouble in his case. His attendances, often laboriously undertaken, his prescriptions, soup, rest, bandages, and so forth are to the native so much hocus-pocus, the kind of thing a medicine-man must "keep up" in order to maintain his mysterious prestige. Any good medicine-man, as every primitive knows, has such virtue within him that he could cure a man right away by his mere touch. If, therefore, the native submits to a long and tiresome treatment he does so with his eyes open and as one playing into the hands of a conjurer. He humours the white healer just as he would humour a native wizard. But he expects to be paid in kind for his complaisance. "I have played into your hands, my good sir," he says in effect, "and I deserve a reward—a yard or two of cloth, or a pocket-knife. Better still, I deserve to be kept by you in future, fed, clothed, and all." The Rev. J. Mackenzie had cared for and cured a native whose face had been terribly lacerated by a tiger. "My mouth is not exactly where it used to be," said the native condescendingly, ". . . but the wound is quite whole. Everybody said I should die, but your herbs cured me. You are now my white man; please to give me a knife." After some further pour-parlers the medical missionary "gave the man up as a very wonderful specimen of jumbled ideas." But the man was less oblique than his mouth. He was following, as Prof. Lévy-Bruhl clearly shows, a definite line of primitive thought. In allowing himself to be treated by a foreigner, a man with other and distant gods, other "medicine," other habitat, totem, and tribal connexions, he as a good native of the districts north of the Orange River, with his own gods (ancestors), medicine, habitat, totem, and tribalism, had taken immense risks, and, though cured, now found himself a kind of lost soul in limbo, a man cut off from his own ancestral and tribal environment. He now clung to his benefactor, who had become his "white man." And the least that the new white man, now responsible for him in this world and the next, could do was to give him a trifling present, the first of many to come. Sometimes the primitive dodges these vast risks. He lends himself for a specified period to the dangerous alien influences. Thus a powerful South Sea Island potentate allowed his young wife to become a Christian while undergoing a cure, but with the proviso that she was to return to her native gods after the treatment, as she would have to be strangled on the day of his death. She was at least to die in spiritual safety.

We read between the lines in the pages of Prof. Lévy-Bruhl, and are constantly reminded of parallels between the mental attitude of natives and the primitives to be found in many out-patient rooms and poor practices. It is common for hospital patients to believe that by allowing themselves to be treated they confer a favour upon the physician or surgeon. In its crudest form the belief involves the assumption that the doctors should be glad of an opportunity to practise, but the attitude of a "show patient" often indicates a sense of mutual obligation which, if we search our hearts, is not without foundation. Pride in a good job well done, apart from a welcome enhancement of reputation, may stimulate a feeling of gratitude towards the patient who has provided the occasion. That the situation may be recognised by the patient was shown by a wounded soldier who, told that the attempt to save his leg had failed, replied to the surgeon, "Well, sir, I've wanted it off for a long time, but you seemed so interested that I didn't like to say so." In this sentiment, put forward respectfully and with good intent, is expressed the idea of a favour conferred. The medical missionary, like the surgeon in this case, is keen to exercise his art, and the intuitive savage may be trusted to recognise this keenness. From this is a short step to the belief that any obligation is on the side of the healer and this process may account for some of the examples that would not be covered by Prof. Lévy-Bruhl's ingenious generalisation. The fear of the "doctor," the contempt of him, followed by ingratitude or a demand for money, are not unknown to many a surgical dresser in the east ends of large towns. Motives of policy have doubtless restrained our author from emphasising parallels, a large treatise upon which might yet be written.

THE INFLUENCE OF ATMOSPHERIC PRESSURE ON AN ARTIFICIAL PNEUMOTHORAX.

IT has been known for many years that patients undergoing treatment by artificial pneumothorax may experience some discomfort on going from a low to a high altitude, but few exact observations have been made, such as those recorded by Dr. C. Mantoux in *Revue de la Tuberculose* (1923, vol. iv., No. 6). The patient on whom the observations were made was given a refill of 310 c.cm. of nitrogen in the right pleural cavity on Sept. 19th at 1.50 P.M., when the barometer at Chamonix registered 712 mm. of mercury. The initial pressure of −6 was raised to +9 by the injection, the pneumothorax being complete. At 2.25 he left Chamonix, which is 1050 metres above the sea, and he arrived at Montenvers, which is 1914 metres above the sea, at 3.15, experiencing a sensation of fullness in the chest on the way, and slight pain over the base of the left lung on his arrival at Montenvers. A pleural rub, which had not been heard earlier in the day, was now demonstrable over

the base of the left lung. At 3.35 exploratory puncture showed the intrapleural pressure to be +17. The barometer measured 656, or 56 less than the barometer in Chamonix. During the patient's short sojourn at Montenvers, the respiratory discomfort and cough rapidly diminished, and had completely disappeared by 4.10. He left Montenvers at 4.40, reaching Chamonix at 5.25, when the barometric pressure was 709. At 5.55 the pleural rub was found to have disappeared, and the intrapleural pressure to have fallen to nil; on the injection of 100 c.cm. of nitrogen the pressure was again brought up to +9, without causing respiratory distress or the recurrence of a pleural rub and pain. Although it is evident from these observations that the rise in the intrapleural pressure caused by an ascent to a high altitude is rapidly neutralised by the absorption of the gas, some distress may be experienced in the interval by patients with a total pneumothorax which has recently been refilled. A comparison of the barometric with the intrapleural pressures showed that the actual rise of the intrapleural pressure was much less than that which would have occurred had not the gas been rapidly absorbed, and, perhaps, the relation of the bag of gas to the other contents of the thorax changed somewhat. The usual rate of absorption of nitrogen by this patient was 0·25 c.cm. per hour. On the present occasion, however, he had absorbed 100 c.cm. in about four hours. In other words, the rate of absorption had been increased a hundred-fold. The pleural rub heard over the left base had been heard on an earlier occasion when the intrapleural pressure on the right side had been raised to +17, and it was thus evident that this basal pleurisy was a response to an intrapleural pressure on the opposite side exceeding the optimum—an observation which may prove a useful guide when the optimum intrapleural pressure in a given case is being sought.

THE LISTER WARD AT GLASGOW.

ALL hope of the retention of his ward in the Royal Infirmary, Glasgow, as a permanent memorial to Lord Lister would seem to have disappeared with the beginning of its demolition. For more than a week, we are informed, the work of destruction has been in progress, and there does not appear to be any likelihood of its suspension; for the decision of the managers passed unquestioned at the annual meeting of the subscribers on Feb. 11th. If the whole matter be examined impartially, two facts of importance emerge. In the first place, the final decision of the managers to demolish the ward was made in spite of world-wide protest from a large number of medical and scientific societies. The signatures to these formal protests include those of surgeons of international repute, and of high academic dignitaries in many countries. It is evidently their considered opinion that no more suitable monument to Lord Lister and his work could be found than the ward in which his fundamental clinical data were obtained. It must be admitted that the majority of the signatories could not but be in ignorance of the local circumstances which forced the managers to their decision; their protests are therefore based upon sentimental grounds. On the other hand, there has perhaps been a tendency to see in the policy of the managers a continuance of the undoubtedly inconsiderate treatment which Lord Lister experienced at the hands of the controlling body of his time. We feel that the managers must be acquitted of any such charges. The Faculty of Medicine is well represented on the Board, and there can be no doubt that the final decision has been reached from no other motive than an earnest desire to further the economic and scientific weal of the infirmary. Moreover, thorough consideration must have been given to what may be termed "middle course" solutions of the problem, outlines of which have appeared in our columns and in the lay press of the city, and although Mr. James A. Morris (whose first appeal for the preservation of the ward we discussed in October) has issued a further plea, mainly on historical grounds, in which he states that the offer of £2000 for the cost of reconstruction still holds good, no action has as yet been taken on these lines. While the passing of Lister's workshop can only be regarded as the disappearance of a structure which symbolised the most important contribution to surgical science that has ever been made, the decision to demolish the ward has been reached after much consideration by a thoughtful and unbiased body of men. In these circumstances surgical science, and indeed humanity, must accept as his monument, now and in the future, the world-wide continuous application of his principles. From no lips more fittingly than Lord Lister's might there have come the proud declaration:

> "Exegi monumentum aere perennius
> Regalique situ pyramidum altius."

THE PHYSIOLOGY OF THE STOMACH AND DUODENUM.

IN England and the United States the advent of the duodenal tube has been the occasion for a revival of interest in the physiology of the stomach and upper alimentary canal more important than any which has occurred since the publication of the original observations of Pavlov. While the limitations of intubation of the human subject are definite, and the greatest ingenuity can never secure experimental conditions as exact as those given by a healthy animal with an accessory stomach-pouch, the value of experiments done actually upon human beings compensates for this to a considerable degree. The most important contribution to this subject published during the present year is that of M. McC. Baird, J. M. H. Campbell, and J. R. B. Hern, which appears in the current issue of the Guy's Hospital Reports.[1] Not only does this article contain very valuable original observations, but the writers have carried out most painstaking investigations on lines suggested by the work of other researchers. Of these the more important are the experiments in which the total chlorides of samples of gastric contents were estimated at varying periods after meals, confirming the work of C. Bolton and G. W. Goodhart, who proved[2] the importance of regurgitation of duodenal contents into the stomach as the main factor in diminishing gastric acidity in the later stages of gastric digestion. This mechanism was first described by Boldyreff[3] following observations upon animals; its importance was emphasised by T. Izod Bennett and J. A. Ryle[4] in their observations on normal human digestion; and the work of Bolton and Goodhart, confirmed by the present observations, establishes it as a normal part of the gastric digestive function. At the same time Baird, Campbell, and Hern produce new evidence of the action of the pyloric portion of the stomach itself acting as an alkali-secreting medium; here they make use of an ingenious method by which two tubes are employed simultaneously. One, lying in the stomach, enabled them to withdraw fractions of the stomach contents; the other, in the duodenum, was subjected to continuous syphonage, so that the duodenal contents were aspirated and regurgitation into the stomach prevented. This method, which has been employed for somewhat similar purposes by R. K. S. Lim, A. R. Matheson, and W. Schlapp,[5] has the advantage of giving much less complex information, but requires great patience on the part of the subjects experimented on.

In the course of the series of experiments under discussion the observers were again confronted by the paucity of our present knowledge concerning the mechanism of control of the pyloric sphincter.

The acid-control of the pylorus described by Cannon has been criticised by many workers. Baird, Campbell, and Hern, in their experiments, found that the emptying of the stomach occurred at rates by no means dependent upon the acidity of the contents of the pyloric antrum, and often in the presence of duodenal contents of a reaction definitely acid. The last part of their work deals with the problems of achlorhydria. They found that of 60 normal students examined only one showed this phenomenon when subjected to repeated observations, and close examination of this subject threw doubt on the question of his normality. It is admitted that for any adult the definition of health is almost impossible, and one may question whether the other 59 subjects examined would all have stood the test of searching clinical inquiry in this respect. Large numbers of subjects must still be examined before a final answer to this problem can be given; it remains certain that there are a considerable number of persons with achlorhydria living apparently normal lives. It is in connexion with the ætiology of pernicious anæmia that this subject finds its most immediate interest.

OCCUPATIONAL MORTALITY AND INDUSTRIAL UNREST.

THE student of medical sociology who turns to mortality records for some light upon the recent unrest among locomotive engine-drivers finds himself at a loss. The most recent figures published (samples from which are here given) refer, it is true, to 1910–12, but the comparative figure of the Registrar-General's

Comparative Mortality (England and Wales) in Certain Occupations. (Ages 25–64.)

Occupation.	1890–92.	1900–02.	1910–12.
Agricultural labourer ..	731	621	470
Shipbuilding	836	817	633
Railway engine-drivers and stokers	934	610	536
All males	1155	1000	790
Messengers, porters (not railway and Government) ..	1415	1449	1137
Seamen	1564	1646	1485
Costermongers	1911	2007	1507
Dock labourers	2114	1481	1127

occupational group, "engine-driver, stoker, cleaner" was equally satisfactory in 1900–02 and in 1890–92. At no period of life was the mortality experienced excessive, nor was any constituent cause of death in excess. In the *Statistical Bulletin* of the Metropolitan Life Insurance Company of New York for December, 1923, some statistics of the longevity of "locomotive engineers" are quoted, from which the authors infer that engine-drivers have an expectation of life "about as good as that for the average American male of corresponding age," and remark that the special hazards of the occupation "seem not to reduce his longevity prospect below that of males in the general population." We are rather surprised that the American experience is not more favourable. The group, as we have seen, enjoys in this country one of the lowest rates of mortality of any group, a much lower rate than all occupied and retired males, and an appreciably lower rate than members of the civil service. Calling the rate for all males 100, that for engine-drivers was 68, and for the civil service (clerks and officers) 77. This is hardly surprising, since the duties of the occupation can only be performed by physically select men, so that the rate of mortality is hardly a simple criterion of the salubrity of the occupation itself.

On the other hand, mortality data present real excuse for unrest among dock labourers. This occupational group has always stood high for death-rate; in 1910–12 (the last published records) their mortality was only exceeded (omitting occupational groups with special risks, such as silicosis among tin-miners and metal-grinders, and alcoholism among inn-servants and brewers) by costermongers, seamen, and messengers. Dock labour is not a skilled industry, and the unsuccessful of other trades tend to drift to it, as well as to messengering and costermongering. Here lies a reason for much of the high mortality; but low wages, uncertainty of employment, and conditions of work undoubtedly also contribute their share, for these persons need a better rather than a worse environment than obtains under other occupations. The dock labourer suffers in excess from alcoholic diseases and has a reputation for industrial drinking. The contrast between dock labour, shipbuilding, and agriculture is great, although the weather exposure in each is similar. Reference to the great causes of death which contribute to the total mortality discloses that, although all are high, the death-rates of dock labourers from respiratory diseases are particularly excessive.

THE AFTER-CARE OF THE CANCER PATIENT.

THERE are few more tragic figures in human life than the sufferers from malignant disease who daily present themselves for treatment in our hospitals. Apart from the few fortunate ones, in whom a cure is effected, their days will often be numbered; yet how often are they the most cheerful and courageous of patients. Any schemes for after-care, therefore, which shall make for a less distressing end should have a full measure of our sympathy. In the fourteenth report of the Cicely Northcote Trust (October, 1922–October, 1923), recently issued by the Almoner's Department of St. Thomas's Hospital, a lead is given in this direction. The cancer patient, unlike the phthisic, is often a person of middle age, and therefore often with a young family. Struck down in the years of greatest responsibility he must face the prospect of a long illness with an ominous prognosis. Someone is needed, therefore, who can "stand by," who will help the family to carry on and to make those readjustments to life which such a situation necessarily entails. And here the almoner gets her chance—and her privilege. The patient may return home from hospital with a wound to dress or with an inoperable secondary or recurrent growth to deal with, and in the end there may be a long struggle with secondary infection, hæmorrhage or bedsores.

A small booklet on "How to Nurse Cancer Patients,"[1] by the late matron of Chelsea Infirmary, recently published, well emphasises these points. Reading between the lines we can realise how the district nurse who sees the cancer patient in his last stages must improvise again and again to make bricks without straw in the homes of the poor. The Cicely Northcote Trust report also stresses this point; not only medical attendance, but nursing appliances such as hot-water bottles, bed-pans, air-cushions, draw sheets, mackintosh sheets, unlimited supplies of dressings, &c., are required. Very little imagination is needed to visualise the plight of these cases, and we wonder if the time has not come when no case of malignant disease shall be discharged from hospital without definite provision being made for after-care. Such provision would naturally fall under two heads: (1) Adequate arrangements for watching and following up the successful operation cases in view of the possibilities of recurrence; (2) suitable preparations for the last painful months of the inoperable case who will require careful nursing—preparations which must envisage all the possibilities of sepsis, secondary hæmorrhage, and the like. In these matters we might follow the lead of the after-care workers of maternity, child welfare, and tuberculosis schemes, in which departments much valuable work is now being done. It is possible also that a systematic after-care scheme for patients with malignant disease might ultimately produce useful statistics as to complications and sequelæ, duration of life, and even errors of diagnosis. At present we class all these patients together in one group as cases with a hopeless prognosis, whereas careful following up might shed a new light on some of these questions. In this matter medical officers of

[1] How to Nurse Cancer Patients. By E. S. Barton, R.R.C. London: The Scientific Press, Ltd. 1s. 3d.

Poor-law institutions could help. Many cases—notably those after colotomy operations—are transferred from the general hospitals to the infirmaries, and some scheme of collaboration through the hospital almoners might be developed. Finally, the following-up process should be correlated with the new statistical and economic researches on causation. In this matter we believe much more use might be made of the almoner's department than is done at present.

THE FUNCTIONS OF MUCOUS SECRETIONS.

THERE have always been arguments and controversy concerning the function of mucous secretions. The case of saliva is particularly interesting; some physiologists regard its function as mechanical, assisting the passage of food down the upper part of the alimentary tract, others hold that the starch-splitting qualities are by far the more important. Unfortunately for the latter view it is well known that diastase will only digest cooked starch, and since animals (and for that matter primitive man) do not have opportunities for cooking their food, it seems that the diastase can have but little function. In an address which we summarised last week Mr. W. Stuart-Low raises the cognate question of the function of the mucous surfaces and secretions of the nose, throat, and ear. He calls attention to the value of visceral secretions in holding up bacteria. The majority of workers will certainly agree with him so far, but they may not be inclined to put so much faith in the purely chemical action of mucin. Mr. Stuart-Low claims that this substance possesses chemical properties which render it specially objectionable to bacteria. It is pointed out that mucin is rich in oxygen and sulphur, and that it contains a glucosamin radicle, properties which, it is suggested, are in a way anti-bacterial. But a large number of other proteins are rich in oxygen, all the higher ones contain glucosamin, and practically every one contains sulphur. Again, the proteins, considered as a group are unreactive, and mucin is no exception to this. Bacteria are cultured on protein media, the majority of which contain an appreciable quantity of gluco-proteins, such as mucin. So far, then, as our present knowledge goes, the functions of mucin are sufficiently explained in Mr. Stuart-Low's other suggestions—namely, that the bacteria are "trapped" by the sticky secretion, and when thus rendered helpless are demolished by phagocytes.

SURRA OF HORSES AND BAYER "205."

Dr. F. K. Kleine's visit to this country, in order to lay his African experiences before the Royal Society of Tropical Medicine (see p. 384), will quicken the general interest in trypanosome diseases and their relief. To Dr. Kleine's own work we shall return later. The present position is well set out in a careful research on the treatment of surra in horses in Java, recently reported[1] by E. Rodenwalt and J. B. Douwes. They remark that the experimental treatment of trypanosome diseases shows an uninterrupted series of disappointments. Drugs which did well in Europe, curing laboratory animals, laboratory infected with laboratory strains of blood parasites, have disappointed expectations when used in the treatment of the natural disease in the tropics. Bayer "205" gave encouraging results in the treatment of dourine in Europe, though obstinate cases were found and some races of the parasite became resistant. However, dourine is not carried by an insect, but rather in a manner comparable with a laboratory infection, so it cannot be taken closely to resemble the tropical infections. The authors have been examining during two years the treatment of surra in horses by Bayer "205" and observe that only their negative results are final, the positive being still liable to further examination. Only those animals are to be considered—e.g., horses—whose trypanosomiasis takes an acute form, others (buffaloes) which have the disease in a chronic form are apt to mislead for what is judged to be a cure may prove to be only a remission. Horses generally become acutely ill and die in a few weeks. The authors lay stress exclusively on their treatment of naturally infected cases, as many remedies have been known to cure animals artificially infected while failing on the others. They insist on the importance of daily observation of temperature and blood (and that by an expert), for otherwise relapses are missed, and on the duty of keeping the animals throughout the experiment in fly-proof stalls to avoid dissemination of the infection. Fifty per cent. of horses suffer severely from the injection of Bayer "205," equally if they are healthy or infected, native-born or Australian, and even if the doses are very small, too small to be curative. But the trypanosomes are speedily affected, even in a quarter of an hour, disappearing from the blood in 12 hours, and meanwhile losing their power of reproduction. As the horses varied much in susceptibility they were always treated in pairs. It was concluded that the doses affecting the horse and killing the trypanosomes were unpleasantly close together, so big sterilising doses could not be given, the large dose was 2½ per cent. of the body-weight, small doses were ½ per cent. of the body-weight every other day till 5 or 7 per cent. had been administered (in 10 per cent. solution). The large dose may kill the horse, the small one is much less effective. Neither does any good if the disease is well established; they are only profitable if the pyrexia is but slight and there are no parasites to be found in the blood as yet. The disease is so far mastered if the horse does not die at once, but has a relapse after a remission; but relapsing cases are incurable. Ten artificially infected horses, not treated until the disease was well developed, all died. Fourteen naturally infected, all but three died; two are working, one would be, but is too vicious. That a horse is working does not prove it is not a carrier, hence the need for daily controls. Bayer "205" persists longer in the blood than any previous trypanocide, hence its usefulness in prophylaxis. If surra is found among the horses of a regimen the following programme is carried out: (1) Kill all horses seriously ill; (2) treat by injection all animals only slightly affected; (3) kill all relapsing cases; (4) all exposed still healthy animals get a prophylactic injection of ⅔ per cent. of body-weight; (5) horses who become ill are dealt with under (2) or (3); (6) repeat (4) in four weeks' time; (7) buffaloes must also be dealt with; (8) all under treatment are kept in fly-proof stalls. The trypanosomes, if not killed, become resistant within 20 minutes, and are more and more resistant in each succeeding relapse. So the ideal trypanocide is still to seek.

INSULIN BY THE SKIN AND MOUTH.

THE announcement by the Medical Research Council of a 50 per cent. reduction in the retail price of insulin brings the day nearer when this biological will be readily available for study and research. Recent investigations by Dr. A. Wallgren[1] in Gothenburg would seem to suggest that when insulin is rubbed into the skin, enough of the drug is absorbed to affect appreciably the concentration of sugar in the blood. He experimented with the small tablets each containing one Toronto unit of insulin, prepared by the Leo firm of chemists in Helsingborg. The tablets were pulverised, and the powder was first suspended in distilled water. This suspension was then incorporated in a little vaselin or lanolin ointment, and was slowly rubbed into the skin for a few minutes after it had been carefully cleaned with ether. The concentration of sugar in the blood was determined by Bang's method before the inunction of insulin, and for six hours after it, at hourly intervals. The persons examined were children between the ages of 1 and 15 years, convalescent from various diseases. They were given no food during these

[1] Upsala Läkareförenings Förhandlingar, 1924, xxix., 57.

ests in order that alimentary influences should not onfuse the issue. Control tests were also carried ut with lanolin inunction alone, and little or no liminution of the sugar content of the blood in these ontrol cases was observed. As a table showing he influence of insulin inunction in six children learly proves, insulin is easily absorbed by the ntact skin, the action of the insulin, as judged by he concentration of sugar in the blood, being greater n infants than in children of more advanced years. This may be so because the absorptive capacity of he skin declines with years, or because the dose of nsulin relative to the weight of the children was comparatively high in the youngest children examined. n the case of an infant only 1 year old, and veighing 9 kilos, the inunction of insulin reduced he concentration of sugar in the blood so effectively hat the experiment had to be discontinued prenaturely. Before the inunction the concentration of sugar in the blood was 0·094. The corresponding igures for the following six hours were 0·088, 0·073, 0·075, 0·057, 0·055, and 0·049. When this last igure was reached there were signs of a hypoglycæmic reaction, and the infant, who had reacted promptly to the first withdrawals of blood, became more and more indifferent to them. When she was given grape-sugar by the mouth, she at once became brighter and more lively. Experiments on the same lines were also conducted in a case of severe diabetes n a three-year-old child. It was found that the usual morning injection of insulin (2 units) could be satisfactorily replaced by the inunction of 20 units. Dr. Wallgren is inclined to regard these investigations as of speculative rather than of practical value, at any rate for the present. For the percutaneous administration of insulin requires so much of this drug to be effective that the cost of treatment would n most cases be prohibitive. A further disadvantage of the percutaneous route is the comparative inaccuracy of the dosage. But considerable interest attaches to the demonstration of the ability of a hormone to pass through intact skin. In another paper, published by Dr. Ernst Salén,[2] of Sweden, some promising experiments with the oral administration of insulin are recounted. He was unable to confirm the observations of L. B. Winter, who found that when insulin was given by the mouth in an alcoholic solution to rabbits considerable quantities were absorbed in a potent state. But when Dr. Salén gave insulin by the mouth in a suspension of olive oil to three patients suffering from diabetes, he found that in two cases there was an appreciable reduction in the blood-sugar. These and similar investigations afford some grounds for hoping that we may in the near future dispense with the administration of insulin by subcutaneous injection.

WE regret to announce the sudden death, on Sunday, Feb. 17th, of Mr. R. G. P. Lansdown, consulting surgeon to the Bristol General Hospital.

Dr. A. C. O'Sullivan, professor of pathology in Dublin University, died on Feb. 18th from sepsis, contracted a few days before in the course of making a post-mortem examination.

THE anniversary dinner of the Medical Society of London will be held at the Grand Hotel, Trafalgar-square, London, on Wednesday, March 12th, at 7.30 P.M., Dr. Herbert Spencer, the President, in the chair.

---

[2] Acta Med. Scand., 1924, lx., fasc. 1.

NEW HOSPITAL AT ALDERLEY EDGE.—Lord Sheffield, on Feb. 13th, opened a new district hospital at Alderley Edge. The hospital is provided with both public and private wards, and was built by funds left by the late Mr. Otto Baerlein, for many years Serbian Consul in Manchester and a resident in Alderley Edge. The cost of building and equipment was about £11,000.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LIX.—THE TREATMENT OF NEPHRITIS.

I.—General Principles.

THE treatment of nephritis is by no means very satisfactory, and it may be said at once that no drug has any direct beneficial influence on renal lesions. The therapy of renal disease resolves itself into the usual more or less empirical treatment of the various symptoms that may arise; the fundamental lesion itself is unaffected by medicinal measures. While the treatment of symptoms is a simple enough procedure, certain principles underlying the treatment of the disease are still the subject of much controversy and difference of opinion. Though it is quite impossible in the light of our present somewhat limited knowledge to pronounce any definite opinion on certain of the principles advocated in the treatment of renal disease, it is nevertheless clear that physiological considerations may help us in our endeavours to arrive at correct conclusions.

Diet.

The most important question that arises in the treatment of every case of nephritis is that of suitable diet. In the days when physiology was just beginning to explain certain functions of the animal body, it was supposed that protein was partly broken down in the intestine, but that, on absorption, a resynthesis took place, with the result that protein as such was directly passed into the blood. As it was well known that in nephritis protein was excreted by the kidney, the natural deduction was that the less protein given as food, the less work would be thrown on the kidney in excreting this protein. This was the principle underlying the conception which still in large measure prevails, that protein should be given but sparingly in all cases of nephritis. Modern physiology, however, teaches that protein taken as food does not increase directly the protein of the blood, but that food protein is first broken down to the stage of amino-acids in the intestine, and as such is absorbed and circulated in the blood; these amino-acids are picked out of the blood by the various tissues and rebuilt into proteins as required. From this it might be expected that increase in protein food would not increase the amount of protein excreted in the urine in nephritis. Investigation shows that this surmise is correct: the amount of protein excreted in renal disease is not dependent on the amount taken in as food, and no increase or decrease of albuminuria can be brought about by changes in the protein content of the diet. It is therefore clear that no clue as to the amount of protein that should be given in the food can be obtained from an estimation of the amount of protein passed in the urine. On the other hand, it is clear that the more protein taken the greater will be the amount of nitrogenous waste products formed. These products, the chief of which are urea, uric acid, and creatinin, have to be excreted, and in this way their presence may act detrimentally on the kidney, so that in certain conditions limitation of protein may be beneficial.

It should be remembered, however, that there is no proof that protein food is in any way injurious to the kidney, and the usually accepted doctrine that protein is detrimental requires investigation in the light of modern physiological teaching. While it is only common sense to affirm, in the present state of our knowledge, that protein may be injurious in certain cases of advanced renal disease, it is certain that there are numerous cases of nephritis in which the practical withdrawal of protein from the diet does much harm. It is not likely that protein food can produce any injurious effects if the renal con-

dition is such that the kidneys are quite capable of excreting nitrogenous waste products. Frequently certain symptoms of renal involvement are present, but investigation on modern lines shows that there is no interference with the function of excreting waste nitrogenous products. In such patients, protein food may be given with impunity; indeed, these patients frequently improve when given a reasonable amount of protein food, and it is sometimes necessary to include what might be regarded as excessive amounts of protein in the diet. The question of the most suitable diet in any case of nephritis must therefore depend on the state of the kidneys and their power to excrete nitrogenous waste products. If this function is good, protein may be given in whatever amount is considered necessary; if, on the other hand, there is a tendency for the retention of waste products in the blood, it is probably better to limit the amount of nitrogenous food. Everything depends on the nature of the particular case under review, and no general rule can apply to every case. This point will be discussed in greater detail below.

Salt-free Diet.—Many medical men endeavour to restrict the salt intake in all patients suffering from nephritis, but as far as we know at present, there is no sound reason for this procedure unless œdema is prominent. This is the one and only symptom that indicates a diminution in salt intake; the indiscriminate use of a salt-free diet in other cases simply causes inconvenience to the patient and adds greatly to his general discomfort. In many cases of nephritis salt is exceedingly well excreted; when this is not the case, a certain amount is retained in the body. Since it is impossible for the tissue cells to survive if the concentration of salt becomes too great, the body retains water to bring down the concentration to that normally present in the body. Obviously, this mechanism results in the production of œdema. It is not argued, of course, that the sole cause of œdema in nephritis is necessarily salt retention; other factors undoubtedly play a part, but the well-marked diminution of œdema in response to salt-free diet, so often seen in suitable cases, proves that salt retention is, at any rate, frequently a most important actor in the production of œdema in nephritis.

The Blood Pressure.

Attempts to lower the increased blood pressure in chronic nephritis are frequently made, and many methods are used. In my experience no benefit is obtained from such procedures, and in general it would seem that no specific attempt should be made to lower the increased blood pressure of chronic nephritis. This rise of blood pressure undoubtedly serves a purpose, and when it is a secondary symptom dependent on renal change, attempts to lower it may upset the renal excretion. Lowering of the blood pressure by artificial means does not in any way improve the renal function. Indeed, in some patients it would appear as if the increased blood pressure was a most important factor in assisting the diseased renal tissue to perform its function, and when the blood pressure is artificially lowered such patients do not always feel so well. It is often very difficult to affect this raised pressure by therapeutic means, and, on the whole, this is perhaps fortunate for the patient.

Fluid Intake, Œdema, and Diuretics in Nephritis.

It is a common practice to give large amounts of fluid in many cases of nephritis with the idea that the increased flow of urine induced will result in washing out toxic products. Obviously, when œdema is a marked feature, such a procedure can only result in making the condition worse. It is questionable whether large amounts of fluid should ever be given in nephritis. In acute nephritis certainly this practice is contra-indicated, for here we are really dealing with renal cells so extensively damaged that they are for the time being more or less unable to excrete water. No amount of water introduced into the circulation will help to promote renal secretion until the cells recover somewhat, and since in severe cases the body already contains an excessive amount of fluid, the introduction of more fluid simply results in an increase of the œdema. When the renal cells recover and are again able to secrete appreciable amounts of urine, there is practically always more than sufficient fluid in the tissues. The conditions for secretion of urine at this stage are ideal, since the excess of fluid present is practically always associated with more or less increase in the blood pressure; at the same time there is an excessive amount in the blood of urea, which is perhaps the best diuretic we possess. All that is required to produce diuresis, then, is an efficient renal mechanism, and when, therefore, the kidney cells recover, marked diuresis usually takes place, and both fluids and toxins are eliminated. This desirable result, however, cannot be expedited by giving fluid, and there does not appear to be any condition, either in acute or chronic nephritis, in which the introduction of large amounts of fluid into the system is indicated. Indeed, in certain subacute cases when œdema is a prominent feature, reduction of the fluid intake frequently exerts a most beneficial influence. Incidentally, the experience of everyone who has carefully investigated this problem is that the usual diuretics give practically no beneficial result in patients in whom œdema is directly dependent on renal lesions. That marked diuresis frequently follows the use of diuretics in acute nephritis is acknowledged, but since diuresis is the usual outcome in this condition when recovery of the renal cells takes place, it cannot be held to depend on the use of diuretics. It must be remembered that in all severe cases of acute nephritis there is ample diuretic substance—urea—already present in the blood. Contrary, therefore, to what is perhaps the generally accepted opinion, the ordinary diuretics are of little or no value in renal disease, and their use is, with few exceptions, not indicated.

The Use of Alkalies.

In recent years much work has been carried out on so-called acidosis, and since certain features of acidosis are encountered in renal disease, it became the custom some time ago to give alkali in many cases of nephritis. While there is little evidence that the usual small doses of such alkalies as sodium bicarbonate can do any harm when given by mouth, their injection directly into the circulation, in severe conditions of nephritis, is of no value, and indeed sometimes produces alarming results. The particular form of acidosis present in nephritis cannot be counteracted by the use of alkali, since the condition depends on a defective function in the renal substance. The diseased kidney is unable to excrete the excess of alkali, with the result that it is retained in the system, and, like salt, results in the retention of water and an increased œdema. In this connexion it is worth noting that Sellard's simple test for acidosis is of little value in nephritis. Sellard showed that a patient suffering from acidosis could take large amounts of alkali by mouth without the urine becoming alkaline, while the normal individual generally passes an alkaline urine after taking such a comparatively small amount as 5 g. of sodium bicarbonate. Frequently, nephritic patients can take large amounts of sodium bicarbonate without passing an alkaline urine; this, however, merely indicates that the kidney is unable to pass the alkaline sodium bicarbonate into the urine, and provides no evidence whatever of true acidosis. When real acidosis is present the sodium bicarbonate is neutralised by the excess of acid in the body, and so the urine does not become alkaline until the whole of this acid is dealt with. It is because Sellard's test has often been used in nephritis, and the results quoted as indicating acidosis, that the correct interpretation of the results must be insisted on.

Special Articles.

THE WORK OF THE RADIUM INSTITUTE.

THE annual report of the Radium Institute, London, for the year ending Dec. 31st, 1923, has just been issued. We outline here several of the most important features of the report, which deals in particular with radium therapy in diseases of the thyroid, thymus, spleen, and lymphatic system.

Recent Developments in Radium Therapy.

The provision of a limited number of bedrooms in the Institute for the reception of in-patients has proved of very great value. Their existence has rendered possible the carrying out of many surgical procedures which are essential to efficient radium therapy, and, further, it has enabled treatment to be given in a shorter time and with a minimum of fatigue or discomfort. The services of the surgeon are being requisitioned more frequently for the purpose of employing radium in the most effective manner, and recently reported advances in that direction comprise the treatment of laryngeal growths by subhyoid pharyngotomy; and of inoperable cancer of the uterus with extensive infiltration of the broad ligaments, by performing a medium laparotomy and burying the radium tubes in the diseased tissues from the peritoneal surface. Cases of carcinoma of the cardiac end of the œsophagus have also been treated by the introduction of radium tubes through a gastrotomy opening. It appears highly probable that the use of "*surgery of access*" will undergo a steadily progressive development.

The combination of diathermy with radium has, during the past 12 months, yielded some highly successful results in the treatment of carcinoma of the tongue, mouth, tonsils, and fauces, many cases of very advanced type being greatly benefited, the suffering much relieved, and the progress of the disease retarded or arrested. The customary procedure consists of the removal or destruction of the primary focus of the disease by diathermy, excision of the more easily accessible associated lymphatic glands, and a subsequent general radiation of the whole operation area with radium tubes and applicators.

The general trend of radium therapy is in the direction of increase of dose, more especially at the first exposure, and the employment of quantities of radium element varying from 250 to 750 mg., with screening of 2 mm. of lead, and exposure of from 20 to 30 hours' duration, is now by no means unusual in the treatment of such conditions as an extensive mammary cancer, mediastinal growths, lymphosarcoma, lymphadenoma, and lymphatic leukæmia. Patients so treated do experience some degree of systemic disturbance, but it is never very great, and rapidly disappears under appropriate treatment. It is not, however, wise to use such a heavy dose when the radiation is directed chiefly to the abdominal cavity, as recent experimental researches have shown that the mucus-forming cells of the intestines are peculiarly susceptible to gamma rays. The immediate effect of such radiation is a definite but transient increase of activity of the goblet cells, speedily followed by atrophy and degeneration. No mucus being formed the intestinal bacteria are enabled to invade the mucosa, causing its necrosis and desquamation. The bacteria may in some cases penetrate into the blood-stream and give rise to a septicæmia.

Radon.—The use of radon[1] is steadily increasing as its therapeutic value becomes more widely known and appreciated. Advice is freely given to medical practitioners in the treatment of disease with radon apparatus, and if precise information is furnished as to the nature and extent of the disease or growth, a suitable apparatus, correctly screened, with full instructions as to technique and exposure, can usually be forwarded to any address in the British Isles within two or three days. The fact that the therapeutic effect of radon and radium salt apparatus is identical cannot be too strongly emphasised. It is true that radon slowly decays, its initial radioactivity being reduced to one-half in 3·85 days, and to one-fifth in 8·8 days; but this rate of decay never varies, and it is thus a perfectly simple matter to prepare an apparatus, the mean activity of which during a period of 24 hours, would be exactly equivalent to that of a radium salt apparatus of a stated strength. Radon, moreover, has one particular advantage over radium salts, being a gas it is highly compressible, and a curie of radon (the amount of radon in equilibrium with a gramme of radium element) can be contained in a space of only 0·58 c.mm. This property permits of the manufacture of extremely small radon tubes or applicators, possessing a very intense radon activity. Further, radon possesses no intrinsic value, and should a radon applicator be mislaid or destroyed, the only pecuniary loss incurred is the value of the metal container. This enables radon apparatus to be sent on hire or loan to all parts of the United Kingdom, no security or insurance being demanded, as would be the case if radium salt applicators were used.

The Value of Radium in Diseases of the Thyroid.

The normal thyroid gland is but little affected by radium rays, and radium therapy is of doubtful value in the treatment of simple goitres and should never be regarded seriously as an alternative to surgery. In the soft parenchymatous type, however, it may be used with a certain amount of justification, if operative measures have been negatived for any reason.

While in suitable and selected cases of *exophthalmic goitre* the operation of partial thyroidectomy is undoubtedly the procedure offering the best prospects of permanent relief or cure, many patients emphatically refuse operation, and radium treatment is advised.

Prolonged irradiation with the gamma rays often proves most beneficial, especially if there is no vomiting or diarrhœa, and the patient is not emaciated. Flat applicators containing from 70 to 100 mg. of radium element screened with 2 mm. of lead are employed, and a total exposure of from 20 to 30 hours' duration given. The treatment is sometimes followed by a definite exacerbation of all the symptoms, and it seems fair to attribute this to the congestion attendant upon the reaction, causing an increased outflow of the thyroid secretion into the blood-stream. Such exacerbation, however, proves transient, and is usually followed by a gradual but steady and definite improvement in the patient's symptoms and general condition, and this may probably, almost certainly, be ascribed to the action of the rays producing an arrest of the vitality and retardation in the development of actively proliferating cells, thus restoring the output of the cellular secretion more nearly to normal limits. With this there is also associated a fibrosis of the connective tissue of the gland, causing the organ to become firmer and smaller. The patient should be seen at intervals of three months, and the treatment repeated, if necessary, with such modification as may seem advisable.

In advanced and inoperable cases of *malignant goitre* radium treatment should most certainly be adopted. It will often arrest the progress of the disease in a most striking fashion, causing a great reduction in the size of the growth and affording much relief to the symptoms.

The treatment should be carried out by "cross-fire" irradiation with external applicators containing 150 to 250 mg. of radium element, screened with 2 mm. of lead. Exposures of 30 hours' duration repeated at intervals of six weeks are necessary. The employment of radium tubes buried within the growth is strongly to be deprecated, as this procedure is almost inevitably followed by a rapid fungation of the growth through the skin incisions. It is important to preserve the surface of the skin intact as long as possible, as the presence of fungation and ulceration adds greatly to the patient's distress.

[1] In the report of the International Committee on Chemical Elements, 1923, it was advised that the word "radon" should replace the term "radium emanation." The initial activity of all radium emanation apparatus is expressed in millicuries. A millicurie is the amount of emanation in equilibrium with a milligramme of radium element.

When the existence of an enlarged *thymus gland* is suspected a definite diagnosis should be made and treatment carried out by a "cross-fire" radiation of the area with flat applicators containing 50 to 100 mg. radium element screened with 2 mm. of lead should be adopted. The total exposure should be of from 15 to 20 hours' duration, preferably given in three or four equal periods on successive days. The gland rapidly shrinks and a second series of exposures is rarely, if ever, necessary.

Indications for Radium in Enlargement of the Spleen.

Chronic enlargement of the spleen from congestion is met with in hepatic cirrhosis and in chronic cardiac and pulmonary affections. It also occurs in certain constitutional conditions, syphilis, rickets, malaria, and lardaceous disease, but in none of these affections is radium therapy of any practical value. There are, however, three diseases in all of which there is great enlargement of the spleen, and in which radium treatment is indicated, as it rapidly induces a considerable shrinking in the size of the organ with an associated improvement in the patient's general condition.

1. *Splenomegaly—Simple.*—The effect of radium radiation in a case of simple splenomegaly is usually very striking. A spleen which before radiation reaches down into the left iliac fossa rapidly recedes under appropriate dosage, and at the end of six weeks or two months may not be palpable below the costal margin. The radiation of the enlarged organ is best accomplished by means of numerous "half strength" flat surface applicators containing from 200 to 400 mg. of radium element, screened with 2 mm. of lead, the total exposure being of from 20 to 30 hours' duration.

2. *Splenic Anæmia—Banti's Disease.*—In this condition radium usually induces a definite decrease in the size of the spleen, with some slight improvement in the colour index. The disease is, however, a steadily progressive one, and the remission usually proves but temporary, a repetition of the treatment being called for at intervals of from four to six months. Radiation is carried out with "half strength" surface applicators, screened with 2 mm. of lead, and total exposure of from 20 to 30 hours. The amount of radium employed varies with the size of the spleen, but generally quantities of from 100 to 200 mg. of radium element are necessary.

3. *Spleno-Medullary Leukæmia.*—Radium is unquestionably of great value in the treatment of spleno-medullary leukæmia. The immediate result in the improvement of the blood condition is very remarkable. It is often possible to record a definite decrease in the white cell count three days after the termination of the exposure, and this decrease may be steadily maintained for four or five weeks, at the end of which time the number of leucocytes may be reduced to between 20,000–50,000 per cubic millimetre. There is usually, in addition, a concomitant rise in the hæmoglobin content, the anæmia is lessened, and the tendency to hæmorrhages diminished. The patient's general condition is also improved, appetite and strength returning. If the disease is of comparatively recent origin, there is a great decrease in the size of the spleen, the organ rapidly shrinking to almost normal dimensions, and permitting the performance of splenectomy, if this be considered desirable. If the condition is of long standing, and the spleen has previously been subjected to much treatment with X rays, but little actual decrease in its size is likely to be effected by radium, as extensive fibrosis of the splenic interstitial tissue will have taken place. The radiation employed in the treatment of spleno-medullary leukæmia should be wholly of the gamma type. "Half strength" flat surface applicators, screened with 2 mm. of lead, are used, and containing from 100 to 400 mg. of radium element according to size of the spleen. The total radiation should be of from 20 to 30 hours, and, when possible, this should be spaced over two or three days, as by so doing the possibility of inducing some slight systemic disturbance is much lessened. The patients need to be kept under careful observation and periodic examinations of the blood should be made. A steady progressive increase in the leucocyte count should be regarded as an indication for further radium treatment. This is, however, rarely necessary at lesser intervals than four months, and in favourable cases a period of six or nine months may elapse between exposures. In very advanced cases accompanied by severe anæmia transfusion of blood may advantageously be employed between the radium treatments.

Effects of Radium on Certain Lymphatic Affections.

The action of radium rays in the treatment of *tuberculous adenitis* is probably of a two-fold character. Numerous experiments have been made with regard to the action of radium rays on tubercle bacilli, and it has been found that exposures of at least 100 hours' duration with full strength applicators unscreened are necessary to produce a lethal effect. Such exposures are outside the range of practical therapy, and for this reason radium irradiation cannot be used for the distinct purpose of killing tubercle bacilli. It has, however, been noted that cultures of tubercle bacilli which have received a relatively short irradiation have their vitality greatly inhibited, and that sub-cultures made from them grow much more slowly than controls, and exhibit numerous involution forms. It is probable, therefore, that the radiation of tuberculous glands weakens the vitality of the contained tubercle bacilli and enables their destruction to be more readily accomplished by the phagocytic cells. Further, the radium irradiation acts as a stimulus to the production of fibroblasts with the consequent development of an encircling, constricting, and protective fibrosis

In the early stages of the disease, when the glands are relatively small, discrete, and but little tender, appropriate radium treatment will usually speedily reduce their size and number and arrest the progress of the disease. If caseation or suppuration has occurred, it is, however, imperative that before radium treatment be given the contents of the glands should be removed, either by aspiration or free incision and drainage. Some judgment must be exercised in the treatment of tuberculous adenitis, and the strength of apparatus, screening, and length of exposure modified according to the nature of the individual case. When the covering skin is not implicated, "half strength" applicators, screened with 2 mm. of lead, and exposures of from 20 to 30 hours' duration give the best results; but when chronic sinuses exist and the skin is infiltrated or ulcerated, screening of 1 mm. of silver or 0·1 mm. of lead is preferable, the length of the exposures being shortened accordingly.

Lymphadenoma usually exhibits an exceedingly favourable response to radium therapy, more especially when the superficial glands only are affected and no enlargement of the spleen, liver, or mesenteric glands is appreciable.

The position of the enlarged glands generally renders the application of "cross-fire" radiation practicable, and if this method of treatment be conducted with suitable sized "half strength" applicators, screened with 2 mm. of lead, and exposures of 20 to 30 hours' duration, the glands rapidly diminish in size and number, this effect being often clearly perceptible to the patients themselves within a week of the exposures. The duration of the remission varies very widely. In some cases the disease will remain quiescent for 12, 15, or 18 months, in others a repetition of the treatment may be found necessary at intervals of six months, but none the less radium treatment is to be advocated, as it will prolong the patient's life considerably, and postpone the appearance of a secondary anæmia and its accompanying symptoms.

It is in the treatment of *lympho-sarcomata* that the most spectacular results of radium therapy are to be seen. The lympho-sarcoma cell is peculiarly susceptible to gamma radiation and its degeneration rapidly occurs. The rapid degeneration and absorption of the lympho-sarcomatous cells, however, necessarily produces an auto-toxæmia, and the systemic disturbance is generally considerable, sickness, lassitude, headache, and a rise of temperature being pronounced features.

The patient should be kept strictly at rest, and laxatives and diuretics judiciously administered, until the symptoms have subsided. It is not necessary or advisable to treat lympho-sarcomata by the burying of radium tubes in the substance of the growths. The tumours exhibit a great tendency to fungation when once any breach of the covering skin has occurred, and for this reason the surface should be kept intact as long as is possible. "Cross-fire" radiation will do all that is required, and it is justifiable, in view of the extreme malignancy of the disease, to use a very large quantity of radium—400 to 700 mg. of radium element, screened with 2 mm. of lead, and a total exposure of 30 hours have been employed in some extreme cases with most gratifying results.

Radium treatment is very effective in improving the condition of the blood in *lymphatic leukæmia*. The lymphocyte is probably, almost certainly, the most susceptible of all cells to radium, and for this reason radiation of the enlarged glands is speedily followed by a very definite decrease in the total number and percentage proportion of the lymphocytes. With this fall there is usually associated an improvement in the general symptoms, and the patient's health is decidedly benefited. It is, however, extremely difficult to predict how long the improvement will last. In a few cases the disease will remain quiescent for a year or 18 months, but, as a general rule, indications of a relapse appear in between four and six months, and a repetition of the treatment becomes imperative. The ultimate prognosis is bad, but the adoption of radium treatment usually effects a considerable prolongation of the patient's life.

Treatment is administered by means of suitable sized "half strength" applicators, screened with 2 mm. of lead, and applied in contact with the surface of the affected glands. The total quantity of radium used is dependent upon the number and size of the glands treated, but generally amounts of between 100 and 300 mg. radium element will suffice. The total exposure should be of from 24 to 30 hours' duration.

Secondary Tumours.

The treatment of *secondary malignant growths of the lymphatic glands* is mainly surgical, most operations for the treatment of malignant disease being planned on a scale which provides for a wide removal of the associated lymphatics. In many cases, however, radium treatment is employed as an adjunct to surgery, a prolonged screened radiation being given over a wide surrounding area, with the two-fold object of bringing about the degeneration of any scattered or isolated foci of the disease, and of arresting the permeation of malignant cells through the lymphatics. When the removal by dissection of malignant glands is impossible or inadvisable, radium treatment may be adopted, as it will often cause a considerable diminution in their size and arrest the spread of the infection to neighbouring glands. When the masses are superficial, and in easily accessible situations, treatment with buried radium tubes, screened with 1·0 mm. of silver or 0·3 mm. of platinum, is to be advocated. When deeply situated, or attached to important structures, blood-vessels, or nerves, the prolonged screened radiation from "full strength" applicators is to be preferred.

It is impossible to lay down any hard-and-fast rule as to dosage; the amount of radium used, screening employed, and exposure given having to be adjusted to the requirements of the case. Speaking in general terms, however, when buried tubes are used the exposure should vary from 18 to 24 hours. When prolonged radiation from external applicators is adopted the screening should be 2 mm. of lead and the total exposure of from 20 to 30 hours. If benefit result, the treatment may be repeated at intervals of five to six weeks.

CHANGING FACTORY CONDITIONS.

III.—PROBABLE FUTURE DEVELOPMENTS.[1]

IN the welter of events and of emotions in which we have lived since the closing days of July, 1914, it has been difficult to say what would be lasting and what was merely passing, in relation to industry in particular as in relation to all movements of civilisation. Since the armistice we have had abnormal trade fluctuations. The colossal happenings of these years have bred new hopes, passing sometimes into sheer extravagances, as to industrial possibilities; and by a natural revulsion of feeling, many have been carried to the opposite extremes of reaction or despair. There are many signs now of a settling down to a less unstable state of affairs, and to reasonable ambitions and projects; and it is not entirely rash to forecast likely developments both of legislation and of administration, or to attempt to estimate the attitude and action of those engaged in industry, whether employers or employed.

General Need for New Legislation.

In the first place it is generally expected that a new and comprehensive Factory Bill will be brought before Parliament at the first good opportunity. Twenty years form a long period, especially when they are years in which experience has grown and views have changed. The Factory Act of 1901 no longer seems adequate.

One of the first things to consider in connexion with any new Factory Act should be whether there are any new classes of workers to be brought within its scope. At present warehousemen have very little protection; and clerks have none at all, beyond that which the ordinary by-laws as to sanitation impose upon any building used by human beings. It is notorious that both warehouses and offices can be most unwholesome places to work in. Protection should certainly be extended to both clerks and warehousemen, though it is not at all sure that it would best be done by widening the scope of the Factory Acts to include them, or whether such inclusion would be welcome to those who conduct office business. What is important is that the occasion of the introduction of a new Factory Bill should be taken to review the protection of all workers. Our industrial legislation has grown up piecemeal as different abuses have been perceived or different classes of workers have attracted attention and sympathy; the time has come to build more systematically. There is no reason why a man who paints the bottom of a ship or a railway bridge should come under regulations intended to minimise the danger of lead poisoning whilst a man who paints a house does not. There is no reason for maintaining any longer the historic distinction between textile and non-textile factories. And there ought to be a frank abandonment of the old idea, half abandoned in practice but still leaving its traces all over our industrial legislation, that men do not need protection against industrial evils. The most glaring example is that of hours; men may, and sometimes do, work for terribly long periods at a stretch, notably at the docks. The existing Factory Acts, and the regulations drawn up under them, should be scrutinised to see which distinctions made in conditions imposed as to men and as to women are based on genuine requirements of different sexes, and which are survivals of the old notion that the State should not interfere with the employment of adult men. If it should be objected still that men are strong enough to force better conditions by trade-union action, whenever they really desire them, the answer surely is that their health and safety do not concern themselves alone but that the whole community has an interest in them. If from neglect of proper precautions the health of men in any industry, or of some of them, is injured, it is extremely likely that sooner or later they, or members of their families, will become a burden upon the community.

The Requirements of a New Factory Act.

One of the requirements of a new Factory Act would certainly be adequate lighting in all factories and workshops. And not only adequate lighting but *suitable* lighting, without dazzle or glare or flicker. The Departmental Committee on lighting reported very fully in 1915 and again in 1921, and it called attention to the legislation of foreign countries in this matter. There should be no great difficulty here; the main question would be to settle what should go into the Act itself, and what should be left to the Home Secretary to prescribe by regulation for the various trades and processes. The Departmental Committee recommended that the illumination in an ordinary workroom should be not less than 0·25 foot-candle on a horizontal plane at floor level; that

[1] The previous articles in this series appeared in THE LANCET of Feb. 9th and 16th respectively.

in other parts of factories or workshops it should be not less than 0·1 foot-candle; and in yards, approaches, and so on, not less than 0·05 foot-candle. In the case of iron foundries, in which the accident rate has been very high, they recommended an illumination of not less than 0·4 foot-candle. There is no great difficulty in measuring illumination by a photometer, and there is foreign experience to show that such definite standards are practicable. The gain to the workers both in health and in safety should be considerable.

Another requirement is the regulation of weight-lifting. Strains and ruptures are only too common among men, notably at the docks. It was the frequent occurrence of hernia among certain classes of workers at Bournville which led to the provision by the firm of special gymnastic training and instruction in weight-carrying, but few firms are so careful of their workers' welfare as Messrs. Cadbury. The bad effects of lifting and carrying heavy weights show themselves more often in general fatigue and over-strain than in definite accidents; as the Departmental Committee on Accidents phrased it, "it is a matter of health rather than of safety." The subject has received attention for at least 25 years past, but not much has been done. Some small protection is afforded by the law to women and young persons; in the case of the latter the certifying surgeons can attach conditions to the certificate of fitness; and both women and young persons are excluded from very heavy work in the pottery industry and in one or two other industries. But only the fringe of the evil has been touched. It must be admitted that legislation as to weight-lifting and weight-carrying would not be easy to enforce.

Further, a new Act should require the proper spacing of machinery. It should substitute also the "safe-guarding" of machinery for the present requirements of "fencing" and "guarding"; the former term is wider and would cover precautions which do not come under either of the latter heads, such as provision of automatic feeding arrangements. A clause is also wanted requiring the maintenance in good condition, both as regards repair and cleanliness, of all floors, passages, and stairways. Whether a new Factory Act should attempt to regulate the manufacture of machinery is more controversial; there would be difficulties connected with the import and export of machinery, and perhaps it is a matter which will have to wait for international action.

It was the distinctive feature of the Police, Factories, &c. (Miscellaneous Provisions), Act of 1916 that it gave the Home Secretary power to prescribe welfare conditions in industries which were not technically "dangerous." Those who frame a new Act will have to consider carefully what powers of this kind they want to allow. Is there any reason why the provision of hot water for washing purposes should not be made compulsory on all factories and workshops and for every kind of worker? It seems a very elementary hygienic need.

The present legal enactments are nowhere more thoroughly out of date than in provisions as to hours. They still allow a 10½-hour day and a 60-hour week to women and young persons in non-textile factories. (There are a good many exceptions and special provisions for special industries, but that is the broad rule.) Industrial practice is far away from what is allowed, and a 48-hour week or a 44-hour week are most commonly worked to-day. But they should not be left to the power of the trade-unions to enforce or to the goodwill and the good sense of the employers to allow. The community should register its unwillingness to tolerate long hours. Moreover, this country ought to ratify the first convention of the first meeting of the International Labour Organisation of the League of Nations, which specified an eight-hour day and 48-hour week as a normal legal maximum.

International Organisation: the Power of Research.

Industrial legislation and administration in this country, and in all other civilised countries, are likely to be profoundly affected by the new International Labour Organisation, unless indeed the League of Nations fails to establish itself—a contingency which is better not contemplated. The steady comparison of the legislation of different countries is bound to result in levelling up; each country will doubtless be anxious to press upon other countries the adoption of restrictions which they have placed upon their own manufacturers. Concerted action should also make possible legislation in some directions in which the separate nations have feared to move because of competition; there have been one or two conspicuous examples in the past of what is possible to united action, notably the proscription of white phosphorus and the prohibition of night work of women; and now with properly constituted and permanent machinery much more should be achieved. We must reckon, however, with the possibility that the existence of the International Labour Organisation may act also to some extent as a brake; nations may not be quite so ready to make experiments in advance of other nations, and the opponents of innovation will be able to suggest, with rather more case, that we ought to wait for other countries to take action also.

It is impossible to over-stress the importance of research and the benefits which might accrue to the workers in industry if money were spent more freely on it. It is encouraging to note, as the Chief Inspector of Factories notes in a recent annual report, that trade associations are spending a good deal more in this direction than in the past. There is also the important work of the Medical Research Council, which might, of course, be multiplied many times with advantage. The coöperation of medical men and of industrial chemists has accomplished much in the past, and there is vastly more which it is likely to achieve. A very valuable sphere of research just at present is the causation of dermatitis in its many forms. Sugar-workers, oil-workers, women who peel oranges, men who handle box-wood, and many others, are liable to affections of the skin, which may be more annoying than serious, but which may in some cases have very serious consequences. It is important, and not always easy, to discover exactly which volatile oil or other ingredient is the cause of the mischief and what the precise action is. Until that is known, precautionary measures may either fail or they may be unnecessarily cumbersome and vexatious. There is also much experiment still needed on substitutes for dangerous materials. Phosphorus poisoning has disappeared, or almost so, not because of elaborate regulations hedging its use, but because it was found possible to prohibit altogether the use of white phosphorus. In the same way it would do more for the health of certain classes of workers—e.g., coach-painters and house-painters—if the use of lead in paint could be prohibited; but there is still a good deal of work to be done before we can tell definitely to what extent zinc compounds or other substances can replace lead compounds and give as good service. Along all such lines research undertaken in different countries would have the advantage of pooling varying experiences of the troubles and varying methods of meeting them.

The same may be said of ventilation. Here, where there is distinct room for great reform, there seems to be a shortage of men with expert knowledge. The removal of steam from dyeing sheds is often a difficulty as to which employers would welcome advice. Great progress has been made of recent years in the removal of dust and fumes, and there is reason to believe that we are on the threshold of further improvements of far-reaching effect. Dr. J. S. Owens's Dust Counter,[2] which enables us to take an exact measure of the solid impurities in the air, may well make a revolution in the health of some of the grinding trades. The difficulty here has been to make both employers and workpeople realise the dangers arising from the presence in the atmosphere of minute and invisible particles of silica. Because no

[2] THE LANCET Supplement on Atmospheric Pollution, June 13th, 1919.

dust could be seen, they assumed that there was no dust to do any harm. But it is precisely the invisible particles of silica which penetrate to the lungs and cause fibrosis. It is now possible, without excessive difficulty, to demonstrate the presence of injurious dust in a room which appears to be dustless, and to give a reasonably exact account of its quantity and composition.

The Need for Standards.

Attention should be drawn to the growing requirement of exact measurements in industrial legislation. Subjective standards such as "adequate," "reasonable," "suitable," are being replaced in many directions by precise objective standards. Examples of this are to be found in the Cotton Cloth Factories Acts, with their standards of humidity measured by hygrometers, in the regulations for wool-sorting which prescribe the velocity of exhaust draught for various purposes, in the regulations for spinning and weaving flax which fix a minimum permitted temperature. The recommendations of the Departmental Committee on Lighting are another case in point. Perhaps one of the weakest places in our system of industrial regulation is the lack of standards of competence for men who are placed in responsible positions. The Coal Mines Acts require that managers and other officials of coal-mines shall have passed examinations and shall hold certificates that they are fitted for their work. Similar safeguards would be very useful in many other industries. There is nothing at present to guarantee that a man who undertakes the responsibilities of an industrial enterprise has the technical knowledge necessary for his task. There have been cases of collapse of buildings in the last year or so where it was clear that structural alterations, or alterations in use, were made by men who did not understand their work. One disastrous explosion not long ago was obviously due to the same cause. The health and safety of the workers ought not to be jeopardised in this way. The chief difficulty at present is the lack of recognised and well-graded diplomas or other guarantees of competence in the majority of industries.

The General Message.

The greatest progress in industrial welfare is to be made, not in reducing the diseases or the dangers special to some of the more objectionable processes, but in raising the standard of health and well-being of the ordinary worker at ordinary jobs. Even in the case of the specific industrial diseases, half the battle has been to get the ordinary rules of health observed. It was not simply lead poisoning which caused such a huge sickness and fatality list 20, 30, 40 years back; it was the exposure to lead of men and women, often of children, who were underfed, over-tired, and ignorant of many of the common decencies of life. The higher standards of life generally have done a great deal, quite apart from the effects of special regulations, to reduce industrial disease.

The use of hot water, care of the teeth, more frequent change of clothing, shorter hours, more and better food, all these have contributed to the rising standard of health. Town-planning is another new factor which is likely to make a tremendous difference to the lives of the industrial population of the next generation and perhaps still more of the next generation but one. The community to-day has a new collective conscience and a new collective imagination, employers are alive to their responsibilities to their workers as they were not before the war; the workers themselves are better fed, more intelligent, and they are claiming and getting a larger share in shaping the conditions under which they work. Regulations, research, experiment, propaganda, these are only the means to a desired end; and they are only likely to be efficacious in so far as the end is clearly conceived and really desired by a large number of persons, and especially by those chiefly concerned, the organisers of industry and the workers themselves. And where the ends are desired the means will be found. The most encouraging sign of our time is not the technical advance, though that is of high importance, but the new conception of industrial life as a thing which might be, and should be, healthy and educative and a good thing in itself.

THE IRISH MEDICAL COMMITTEE.

(FROM OUR DUBLIN CORRESPONDENT.)

FOR some years past the organisation of the Irish medical profession has been very defective, and medical men have seemed to be without interest in any medico-political matter. It looks, however, as if this period of inertia were nearing an end, if one may judge from proceedings of the Irish Medical Committee which sat on Feb. 13th.

The meeting had been summoned to consider the proposal of the Insurance Commission to reduce the payment for certification under the National Health Insurance Acts, and the intention of the Government to appoint a Committee of Inquiry into the public medical services of the Free State. As will be seen from the appended resolutions, the Irish Medical Committee only agreed to accept the revised rate of payment for certification for a limited period. It has also asked the Government that, in accordance with the precedent of the appointment of the Irish Public Health Council in 1919, the Irish Medical Committee should nominate some of the persons to act on the Committee of Inquiry. The Irish Medical Committee also considered the necessity for a thorough organisation of the medical profession throughout the Free State. Arrangements are to be made for the signing of pledges of all medical practitioners to bind themselves to act together in any emergency that may arise to threaten their interests.

The following is the series of resolutions adopted by the meeting:—

1. That the Irish Medical Committee, on behalf of the Irish medical profession, strongly protests against the reduction of the remuneration for medical certification under the Insurance Act; that the Committee only agrees to accept the terms now offered by the Irish Insurance Commission until August 31st next.

2. That pending the result of the proposed Committee of Inquiry, outlined in the letter of the Chairman of the Irish Insurance Commission, the profession be organised thoroughly in each county in Ireland; that a medical organiser be appointed forthwith and, to meet the expenses of his appointment, &c., a levy of £2 be made upon each member of the profession in Ireland—the levy to be voluntary in the case of those members of the profession who are already subscribers *to both medical organisations in Ireland.*

3. That in the event of the report of the Committee of Inquiry being either unsatisfactory or the Dail refusing to enact medical legislation providing efficient medical services for the people and on terms acceptable to the profession, the Committee recommends that a delegates' meeting be summoned to consider the advisability of withdrawing from the public medical services.

4. That the details of organisation such as the signing of pledges, arrangement for making the levy, &c., be left in the hands of the Executive Committee appointed by the Irish Medical Committee at its meetings held on June 20th, 1923, and Feb. 13th, 1924.

5. That the scales of salaries adopted by the profession in Great Britain for whole-time medical officers, tuberculosis officers, medical school inspectors, &c., be applicable to Ireland.

6. Arising out of Sir Joseph Glynn's letter of Dec. 27th, 1923, the Minister of Finance be requested to invite the Irish Medical Committee, in accordance with custom, to nominate representatives of the medical profession in the Free State to act on the proposed Committee of Inquiry.

7. That the Irish Medical Committee is of opinion that in the best interests of the medical profession the medical schools and clinical hospitals should arrange for a short course of professional ethics for their senior students.

Finally, the Executive Committee was instructed to arrange for a deputation to wait on the Minister of Finance with regard to the taxation of motor-cars used by medical practitioners.

Correspondence.

"Audi alteram partem."

IN HONOUR OF DR. BRACKENBURY.

To the Editor of THE LANCET.

SIR,—There has been a very widely expressed desire that the eminent services of Dr. H. B. Brackenbury to the medical profession should be recognised, having regard particularly to his recent most useful and brilliant work in preparing and presenting the case of the insurance practitioner before the Court of Inquiry. Steps are already being taken to approach insurance practitioners through their panel committees, as it is thought that insurance practitioners as such would desire to have a special opportunity of expressing their gratitude. But our correspondence and conversations with many colleagues show that numerous doctors having no connexion with insurance practice would be glad of an opportunity of showing their belief that Dr. Brackenbury's services for many years past have been of great value to the profession as a whole. They consider that Dr. Brackenbury's recent advocacy and conduct of the case of the insurance practitioner have been such as to enhance very considerably the reputation, influence, and prestige of the medical profession. A large and influential committee is now being formed, and an opportunity will shortly be given to those who wish to join in a well-earned tribute to one who has rendered unique services to his profession.

We are, Sir, yours faithfully,

J. F. ALLAN (Bradford).

THE POSITION OF PSYCHO-ANALYSTS.

To the Editor of THE LANCET.

SIR,—Some aspects of the recent development of clinical psychology seem to call for serious attention. There are medical men of repute and academic standing who practise psycho-analysis or, without practising it, regard it as containing a valuable contribution to medical knowledge. Others have adopted it as a specialty without that arduous apprenticeship which should precede specialism, and there is an uncertain number of lay analysts who make no pretence to medical knowledge. We see the daily press giving prominence to denunciations of psycho-analysis by members of our own profession, and that this takes place without protest or disclaimer indicates a sentiment which regards our psycho-analytical colleagues as without the law. Though within the narrower circle of professional discussion we no longer hear demands that psycho-analysis should be suppressed, and the tone of its opponents is more moderate than it was a few years ago, yet feeling is still so strong that some degree of courage would be required for an aspirant to professional advancement to announce his belief in the doctrine. This state of affairs has precedents in the history of medicine, and it is possible that medical history is in the making without our recognising the process.

When it is considered that the theory is now nearly thirty years old, that it has met with opposition as forcible as any in the history of scientific controversy, and that its supporters are nevertheless becoming more numerous both within and without our profession, it is plain that we are dealing with no ephemeral cult but with something possessed of strong powers of survival. It is to be noted, too, that its most conspicuous opponents are men of ripe or even advanced years, and though for a new theory to be strenuously opposed is no hall-mark of soundness, yet in other respects than this the parallel still holds good, and the comparison of Freud with Harvey and Darwin, seriously advanced by his admirers and derided by his opponents, may ultimately stand confirmed. It has been hitherto assumed that all mental processes are conscious; in fact, this assumption is given axiomatic validity and used as an a priori argument to dismiss the whole theory of the unconscious, and the discovery of its invalidity will make Freud's main theory, if ultimately incorporated with our scientific principles, a landmark in the advance of knowledge, and for the very reason that it overturns the universal assumption.

But its clinical applications are our more immediate concern, and it must not be overlooked that the theory has been postulated, not for its own sake, but as a means of resuming, in convenient form, observations which many responsible medical men claim to have confirmed. Psycho-analysis is claimed to provide a psycho-pathology of mental disorders, particularly of those psycho-neurotic troubles that have been a reproach to medicine and the hunting ground of miracle-workers and charlatans. In the heat of controversy it is not likely that its cures can be properly adjudged, but, in spite of alarmist accounts, it probably has fewer failures to its discredit, in the shape of suicide or insanity, than has the rest-cure for neurasthenia. One can hardly understand why psycho-analysis, if its good results are non-existent and its methods are based upon delusion, should not be allowed to die a natural death without undue fuss or attention. If, however, it stands the test of time it should greatly enrich clinical medicine and benefit a group of sufferers for whom orthodox therapy offers but little. Meanwhile we must avoid an attitude which may intimidate honest workers, especially younger men who may fear that their careers would be prejudiced

if they attempted, by clinical investigation, to establish or confute the important principles involved in this controversy. And we must take care lest we afford another target for the gibe that mankind learns nothing from history.—I am, Sir, yours faithfully,

Feb. 13th, 1924, A TEACHER.

ELECTRONIC REACTIONS OF ABRAMS.

To the Editor of THE LANCET.

SIR,—In adding my contribution to the discussion on E.R.A. I would first state my position. I was asked to proceed to San Francisco to investigate the question by a layman, who felt that it would be an act of philanthropy if Abrams's claims were well founded, to put at the disposal of the medical profession for use among the poor and for research the armamentarium required. It was not surprising to me that many medical friends deprecated the prospective waste of time, and one of my most respected quondam teachers—and subsequent colleague—implored me not to bring discredit on the Cambridge School by running off the rails. My reply was that only by an unbiased attempt to sift the wheat from the chaff could one justify oneself scientifically. But even yet I asked myself whether I possessed the necessary knowledge of higher physics to make satisfactory critical observations or the necessary capacity for critical expression of the truth. My thoughts recurred to Sir Thomas Browne (Religio Medici) :—

"Every man is not a proper champion of the truth nor fit to take up the gauntlet in the cause of verity; many, from the ignorance of these maxims, and an inconsiderate zeal unto truth, have too rashly charged the troops of error, and remain as trophies unto the enemies of truth."

Being pressed, I accepted the mission, and set myself to follow the following lines of thought :—

(1) Did something happen, palpable, tangible, audible at the moment that the "diagnosis" was being made?

(2) If so, could this something be correlated (with any kind of constancy) with any normal or abnormal quality or function of a patient which might be or have been empirically tabulated?

(3) Was there any evidence that in the treatment given the patient derived benefit not reasonably to be attributed to suggestion?

I realised the possibility of Abrams's facts being correct while his explanations were faulty. But I reckoned without my hosts (Abrams and his followers). The first difficulty I experienced reminded me of the dictum of Hobbes in the "Leviathan": "Words are wise men's counters, they do but reckon by them; but they are the money of fools." It was clear that with the best will on my part I was unable to get into touch with their *minds*. To my questions the answers appeared to me to be conscious, or (more often) unconscious, camouflage. Categories were mingled in a way which satisfied me that it was a disability and not malice-aforethought which inhibited their logic. One enthusiast in reply to my comment that he was not logical, said: "Don't you realise, doctor, that this transcends logic." I could only bow.

I know that I shall be held guilty of violating the spirit of the old motto, "De Mortuis," in expressing an opinion (which is only my opinion and therefore lacks evidence) that the one worker who *consciously* made the *suggestio falsi* or the *suppressio veri* was Abrams himself. Of the other inquirers and practitioners, some were enthusiastic optimists to whom the wish was father to the thought, while some were men of scientific mind honestly trying (and hoping) to find enough evidence to support their actions. At least one of these told me with a sad heart that he was being forced to the conclusion that, though he still felt something did happen with the "box," he was totally unable to verify any correlation with any demonstrable pathological states—in other words, that he found himself unsatisfied that his diagnoses had any meaning.

Before approaching the magician's castle I was warned that I should find torpedo nets, in the shape of banter, irritability, and verbosity spread out all round him to fend off the direct question. This I found to be so. He received me courteously, but was entirely intolerant of any analysis of his ex cathedra statements. In one case, which appeared to be a typical scirrhous carcinoma of the breast about to fungate, he stated that his machine gave "no carcinoma reaction, sarcoma reaction," and, turning to me, said, "we treat these cases in the orthodox manner," and then told the patient she would be given a little "burning" treatment which would cause her no discomfort. On inquiry I was told, "Oh, we bake these!" but I was not enlightened as to the technique. I then asked if by sarcoma he meant a quickly-growing highly-cellular growth with very little intercellular stroma, to which he replied, "Oh, I use the term in a rather more general sense than that!"

I told him that, for me, a most helpful means of estimating the question of his good faith (apart from any success in diagnosis) would be the historical method of learning what led him over the enormous gap between his first recognition of his "reflexes" and the conception of the "box." He entirely avoided this line of inquiry. Asked if he regarded the phenomena as electrical, he said he did not know, and excused the use of the terms electron, "ohmage," &c., on the ground that "you must have some terms for the purpose of description." I became satisfied that he had no first-hand knowledge of electrophysics at all, which opinion was expressed (from a study of his publications) by the great physicist, Dr. Millikan, the American Nobel prizeman, in a paper before the Los Angeles Medical Society, when he said "it is not mediæval but prehistoric."

Now for a few words about the machines. While not myself qualified to dogmatise upon the possibility of the creation or modification of any physical "influences" upon the patient, one can state that the diagnostic box is in fact composed of a series of rheostats of small and variable resistance, which resistance does roughly correspond in units to the figures marked outside. In so far as an electrical current from without or a difference of potential occurring within the limits of the subject's body required that amount of resistance to get a particular result, it is at least conceivable that *something* might be measured; but in so far as statements are made as to rates of electronic vibration being "let through" it is so much verbose "flapdoodle."

As regards the oscilloclast, for treatment, I cannot affirm or deny that it has some physical influence, any more than I can affirm or deny that the laying-on of hands or extreme unction can have a physical (as opposed to a symbolical or suggestive effect), but it is quite clear that no one has yet been able to show by any method of physical measurement or demonstration that such occurs. We have, of course, all been told of cases which have been cured. I have had no opportunity of judging if they are truly reported. I shall not seek them, as I think my time will be better spent otherwise, but I should be one of the first sympathetically to investigate any case in which accuracy of information could be reasonably expected from the manner of its presentation. I am, Sir, yours faithfully,

GEO. LYDSTON CRIMP.

Bryanston-street, W., Feb. 19th, 1924.

*** At the District Court of the United States for the Jonesborough District of Arkansas a ruling has just been given in the first important trial involving the electronic reactions of Abrams. Dr. Mary Lecocq was prosecuted for alleged fraudulent use of the mails in connexion with her practice of E.R.A. Dr. Abrams, who had purposed to be present at the trial, was represented by his personal attorney, his unexpected death having occurred on the day preceding the case. After hearing testimony on both sides the Hon. Jacob Trieber pronounced the ruling of the Court as follows: "The Court is still unconvinced of the great curative

properties secured by this treatment, but there is no evidence to justify a finding that this woman did not actually and honestly believe in the success of that treatment or that she did, in undertaking to treat people, do it with the intention of defrauding them." The judge then directed the jury to return a verdict of Not guilty.—ED. L.

LEPROSY: A SELF-HEALING DISEASE.

To the Editor of THE LANCET.

SIR,—In his paper with this title in your issue of Feb. 9th Dr. Ernest Muir says that the significance of the fact that leprosy shows a tendency to spontaneous recovery in many cases does not appear to have been realised by modern writers on leprosy. In my Survey of Leprosy (*Quarterly Review*, April, 1903, No. 394, p. 407) I mentioned that "it cannot be denied that leprosy may be cured, or at least may become spontaneously arrested in its development and flicker out."—I am, Sir, yours faithfully,

GEORGE PERNET, M.D.,
Late English Editor of *Lepra*, the International Journal for Leprosy.

London, W., Feb. 14th, 1924.

ADVERTISING MARGARINE: A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—Some of your readers may have noticed that a certain firm of margarine vendors have recently made use of my name in their advertisements. Such action was, I need hardly say, entirely unauthorised and unwarranted, and I took prompt steps to put a stop to it. I have since received an apology from the advertising agents who were responsible and a promise not to offend again.

I am, Sir, yours faithfully,

C. KILLICK MILLARD,
Feb. 11th, 1924. Medical Officer of Health, Leicester.

SPA TREATMENT AND HYDROGEN-ION CONCENTRATION OF THE BLOOD.

To the Editor of THE LANCET.

SIR,—My attention has been directed by the Buxton Medical Research Society to a leading article in THE LANCET of Dec. 22nd, 1923, headed Spa Treatment and Diuresis, in which it is stated: "Thus it was suggested by one speaker that some spa waters reduce the hydrogen-ion concentration of the blood, an effect which would, in the view of eminent physiologists, be rapidly fatal if it were possible of achievement." The point that you desired to emphasise was, I presume, that large variations in the pH of the blood are impossible without fatal results. With this I entirely agree, and in my remarks to the meeting I said, "for although possible variations in the pH are quite small, an increase from 7.25 to 7.35 ....." I think that no physiologist would venture to state that a variation of 0·1 is impossible. The recent observations of Cullen and Robinson[1] show variations of even greater magnitude. In a subsequent paper[2] they mention cases with recovery from acidosis in which the pH values at 38°C. were 6·98 and 7·02. The variations from the normal in these cases are three to four times greater than the one that I mentioned. A fact that is not generally appreciated is that a variation of 0·1 in the pH is considerable although it does not appear so on account of the mode of expression usually adopted. Thus pH 7·35 represents a hydrogen-ion concentration of $0{\cdot}45 \times 10-7$, and pH 7·25 one of $0{\cdot}56 \times 10-7$, a difference of nearly 25 per cent. This is really considerable although the variation in the pH appears quite small. I am, Sir, yours faithfully,

JOSEPH RACE,
Biochemist.

Devonshire Hospital, Buxton, Feb. 8th, 1924.

Obituary.

BERNARD HARRY WEDD, M.D. LOND., D.P.H.

Dr. B. H. Wedd, former bacteriologist to the London School of Tropical Medicine, died on Jan. 28th, in Ceylon, at the age of 47. He was the fourth son of the late H. A. Wedd, of the Manor House, Woodmansterne, Surrey, and was educated at Harrow. In 1898 he entered Guy's Hospital, and graduated in 1903, obtaining the M.D. in 1906 and the D.P.H. in 1907. After holding various hospital appointments, he became assistant bacteriologist at Guy's; this was followed by his appointment as bacteriologist to the Royal London Ophthalmic Hospital. From 1910–13 he was assistant in the Cancer Research Laboratories of the Middlesex Hospital, and during those years he published several papers of importance on the subject of cancer. In 1914 he became bacteriologist to the London School of Tropical Medicine. He was jointly responsible with his sister, Miss A. F. Wedd, for the English translation of Duclaux's "Pasteur and His Work." At the outbreak of war he joined the R.A.M.C., and went to the front in the 23rd Field Ambulance with the famous Seventh Division, remaining in France, with one interval of a few months' sick-leave, until demobilised in the spring of 1919. His always delicate constitution never recovered from the strain of those five years, and it was during a visit to Ceylon, undertaken for the sake of his health, that he died.

Mr. Bryden Glendining writes as follows: "The many former colleagues of the late B. H. Wedd will have learnt of his recent death with sincere regret. His work in the bacteriological laboratories of several hospitals and in the Middlesex cancer laboratories was marked by an unusual depth of sincerity. His high ideal of research made him very critical of the standard of his own work, so that much was never published, because it failed to attain completeness or required more control experiments than he was able to provide. A man of retiring disposition, he formed few real friendships, but these few friends found his devotion to their service unstinted and his loyalty and kindness abiding. He brought an incisive acumen to bear upon any subject under discussion, and had an astonishingly wide range of general knowledge. His strength of character first revealed itself to me during an acute attack of rheumatic fever, with extensive cardiac complications, soon after he qualified. He struggled for weeks with uncomplaining fortitude in what seemed a hopeless battle, but to everyone's surprise he was again playing tennis, golf, and hockey, at all of which he excelled, a few months later."

JACQUES LOEB, M.D. STRASB.

Dr. J. Loeb, head of the Division of Physiology in the Rockefeller Institute for Medical Research, New York, died at Hamilton, Bermuda, on Feb. 12th, after a brief illness, in his sixty-sixth year. Born in Berlin in 1859 he received his early education there. He studied medicine at the universities of Berlin, Munich, and Strasbourg, graduating M.D. in 1884. His first appointment was as assistant in physiology at the University of Würzburg, returning at the end of two years to a similar post in Strasbourg. In 1891, after a short period of study at the Biological Station at Naples, he went to the United States as professor of biology at Bryn Mawr College. The following year he became assistant to the professor of physiology in Chicago University, whom he succeeded in the chair in 1900. Three years later he became professor of physiology in the University of California, where he remained for seven years until his appointment in 1910 as head of the Department of Experimental Biology at the Rockefeller Institute, New York. As a physiologist Prof. Loeb enjoyed an international reputation. He was the recipient of honorary degrees from Cambridge, Geneva,

Leipzig, and from his alma mater of Strasbourg, and many famous scientific societies and academies in both Europe and America conferred honorary membership upon him. Prof. Loeb was the author of a large number of important works in his own subject. His first publication was a treatise on the Heliotropism of Animals and its Identity with the Heliotropism of Plants, published in Würzburg in 1890. In 1900 he published "The Comparative Physiology of the Brain and Comparative Psychology," followed in 1905 by "Studies in General Physiology," and in the following year by "The Dynamics of Living Matter." In 1912 appeared "The Mechanistic Conception of Life," and in 1913 his brilliant work on "Artificial Parthenogenesis and Fertilisation." In this monograph he described step by step the evolution of his ideas on the subject, as the result of his initial experiments on the eggs of sea-urchins. His work, along with that of Delage in France, and others, showed indisputably that in a number of invertebrates—echinoderms, worms, molluscs, and some insects—it was possible to produce parthenogenetic development through treatment by various chemical and physical means, although the exact nature of the stimulus required could not be determined.

In 1922 he published the results of several years' work on the subject of "Proteins and the Theory of Colloidal Behaviour," in which he contended that colloids combine with acids or alkalis according to the laws of crystalloid chemistry, thus attacking the view that these bodies are governed by two entirely different sets of laws.

Prof. Loeb married in 1891 Anne, daughter of G. H. Leonard, of Easthampton, Massachusetts, and had two sons and one daughter.

CAMPBELL WILLIAM DE MORGAN, M.R.C.S., L.R.C.P. LOND.

THE death of Dr. C. W. De Morgan, on Jan. 27th, at St. Leonards, ends the male line of this distinguished family. Campbell William De Morgan was born at King Williams Town, S. Africa, in 1877, where his father, Dr. Edward Lindsey De Morgan, was in practice. He was the grandson of the mathematician and philosopher Augustus De Morgan, and was named after his uncle William De Morgan, artist, potter, and novelist, and his great uncle Campbell De Morgan, the surgeon, whose memory will be familiar to all medical men in association with "De Morgan spots." He was educated at St. Mary's Hospital, where he qualified M.R.C.S., L.R.C.P. in 1912. After holding appointments at the London Lock Hospital and the Kensington General Hospital he settled in general practice in London. In practice he acquired a host of friends, especially amongst the poor, but he was never ambitious of scientific distinction, and his happiest times were spent, undoubtedly, in the musical and literary circles of Hampstead and Chelsea, where his family connexions gave him a ready entry. During the war he suffered greatly from overwork and some 18 months ago his health broke down completely. He is survived by two sisters.

THE LATE SIR KENNEDY DALZIEL.

WE have received the following personal appreciations of the late Sir Kennedy Dalziel, whose obituary notice appeared in our columns last week.

Mr. Farquhar Macrae, visiting surgeon to the Western Infirmary, Glasgow, writes: "By the death of Sir Kennedy Dalziel, Glasgow and the whole West of Scotland has lost not only an unusually skilful surgeon, but one who occupied a much larger place in the public eye than is usually the case with the successful surgeon, for his interests were wide and were not confined to the merely professional side of life. The writer of this note knew him intimately for over 30 years, first as one of his students, then as his assistant, and latterly as a colleague; and in all these capacities found him equally engaging and equally helpful. His success and the public position he attained were the result of an unusual combination of qualities. Possessed of a fine presence and a manner of great charm and kindliness, he early laid the foundations of his professional success by assiduous study of anatomy when a student under the late Prof. Johnston Symington in Edinburgh, and of pathology during the time he spent in Berlin and Vienna before coming to Glasgow as house surgeon to Sir William Macewen at the Royal Infirmary. Though a complete stranger in Glasgow, his outstanding ability and his obvious bent towards surgery were early recognised, and he soon obtained appointments in the out-patient department of the Western Infirmary and the Children's Hospital.

"Never at any time a great reader or close student of surgical literature, he had an extraordinary capacity for acquiring information, or as he used to phrase it, 'for picking people's brains.' Even knowing this one was constantly surprised at the extent and variety of his knowledge of current surgical opinions and the shrewdness with which he was able to criticise them. As an operator Sir Kennedy Dalziel was facile princeps during the past generation in the West of Scotland. Even in his early days his manipulative dexterity was something to marvel at. Never specially original, he had a mind open to new ideas, and was one of the pioneers in Scotland in abdominal surgery. He was the first to have a recovery after operation for perforated gastric ulcer, and for peritonitis following perforation in enteric fever.

"To those who knew him intimately it was not, however, the surgeon that appealed most, but the man. Full of the milk of human kindness, always genial and enjoying the humour of life, he was a delightful companion. He made few enemies and a host of friends. Even to one who knew him well and appreciated his qualities it was remarkable to find, as one went about the West and South of Scotland during his long last illness, how great was the sense in all grades of society of a personal misfortune and loss. Except Sir Hector Cameron, who is fortunately still with us, no surgeon in the West of Scotland has filled so great a place in the estimation of the public as Sir Kennedy Dalziel, or filled it so adequately."

Prof. T. K. Monro, Regius Professor of the Practice of Medicine in the University of Glasgow, writes: "While the most important estimate of Sir Kennedy Dalziel's work must of necessity come from a surgeon, it is perhaps fitting that a tribute to his memory should be rendered by a physician who knew him well and valued his help very highly. My friendship with Dalziel dated back to 1890, and I believe that in that year I gave the anæsthetic to the first patient on whom he performed abdominal section. My feeling of admiration for his skill and neatness, and for his apparently natural aptitude for that department of practice was not lessened by the subsequent witnessing of many laparotomies performed by himself and others, and I think he was recognised by all as particularly adept in abdominal surgery. He was my colleague at the Western Infirmary from 1913 onwards, and on innumerable occasions my patients had the benefit of his advice, encouragement, and professional skill. His help was given most willingly and his manner with the patients was delightful.

"Dalziel did a good deal of court work in his day, and was well known as a clever witness. He did not publish much, but one of his noteworthy contributions to medical literature was his description in 1913 of the rare condition which he termed chronic interstitial enteritis. In ordinary life he was a most genial and interesting companion. He had an immense practice among rich and poor, and the crowd which assembled at the funeral service in the cathedral and followed his remains to the necropolis included doubtless not a few who were indebted to him for the preservation of their lives or for their restoration to health. To many besides his sorrowing relatives his departure means a great loss."

Medical News.

UNIVERSITY OF OXFORD.—The trustees of the Rockefeller Foundation have offered to the University a gift of £75,000 for the development of the department of biochemistry. A decree was carried without opposition authorising the assignment of a further area of 9 acres of the University park for the extension of the science departments.

In a Congregation held on Feb. 16th the following degrees were conferred:—*D.M.:* S. C. Dyke, Exeter. *B.M.:* B. G. Scholefield, Christ Church.

UNIVERSITY OF LONDON.—The second of the series of four lectures on cancer in the Governors' Hall, St. Thomas's Hospital, Albert Embankment, S.E. 1, by Dr. J. A. Murray, at 5 P.M., on Thursdays, will be given on Feb. 28th, subsequent lectures taking place on March 6th and 13th. The three remaining lectures of the course of four lectures on Blood will be given by Prof. B. J. Collingwood at St. Mary's Hospital Medical School, Praed-street, Paddington, W., at the same dates and time. Attendance at this course is recognised in connexion with the B.Sc. (Honours) Degree in Physiology. Admission to both courses of lectures is free.

Thomas Smythe Hughes Medical Research Fund.—The Senate will proceed shortly to consider applications for grants from this Fund, which are allocated annually for the purpose of assisting original medical research. Applications must be received not earlier than May 1st and not later than June 16th, 1924, and must be accompanied by the names and addresses of not more than two persons to whom reference may be made. Further particulars may be obtained from the Academic Registrar.

A *University Studentship in Physiology*, of the value of £50 for one year, will be awarded to a student qualified to undertake research in physiology, and will be tenable in a physiological laboratory of the University or of a school of the University. A student will not be eligible for re-election. Candidates must be matriculated students or graduates of the University, and must submit a statement of their qualifications, together with the names of three persons as references, when applying the Principal Officer on or before May 31st, 1924. Full regulations for the award of the studentship may be obtained on application.

University College Medical School.—The Senate invite applications for the Graham Scholarship in Pathology, value £300 per annum, in the first instance for two years, founded under the will of the late Dr. Charles Graham to enable "a young man to continue his pathological researches and at the same time to secure his services to the School of Advanced Medical Studies connected with University College Hospital as a teacher under the direction of the professor of pathology." The successful candidate will, if possible, take up the scholarship as from April 1st, 1924. Intending applicants who desire fuller information of the conditions on which the scholarship will be held may call personally on Prof. A. E. Boycott, University College Hospital Medical School, W.C. 1, after having made an appointment. The scholarship is in no way restricted to students either of University College Hospital Medical School or any other medical school of the University of London. Applications, addressed to the Principal Officer, University of London, South Kensington, S.W. 7, must (*a*) be accompanied by the names of not more than three references, one at least of which should be the name of some professor, lecturer, or teacher of the university or college in which the candidate has conducted his studies in pathology, (*b*) state the research upon which the applicant proposes to work, and (*c*) be received not later than the first post on Monday, March 3rd, 1924. Envelopes should be marked "Graham Scholarship."

The Council of King's College have granted the title of Emeritus Professor to Dr. R. H. Steen on his retirement from the Professorship of Psychological Medicine at King's College Hospital.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASE.—An Imperial Social Hygiene Congress, organised by this Council, is to be held at the British Empire Exhibition from May 12th to 16th. The Congress will be opened by the Minister of Health, and a review of the existing situation will be given by the Chief Medical Officer of the Ministry of Health and a medical member of the Scottish Board of Health. The Dominions Overseas and the Crown Colonies have been invited to send representatives. Dame Rachael Crowdy will, it is hoped, open the discussion on the International Aspect of Social Hygiene, and will be followed by Sir Arthur Newsholme and others. On May 13th, under the Presidency of Viscount Astor, Prof. J. A. Thomson and Sir Frederick Mott will define the problem of training the young in sex control, stating the biological and sociological reasons for maintaining a monogamous system of marriage and a stable family. In the afternoon of the same day Mr. James Stewart, the Under Secretary of Health for Scotland, will preside over the Conference, which will discuss the Place of the Local Authority in the Venereal Diseases Campaign, Mr. W. E. Whyte acting as hon. secretary of the section. On May 14th Dr. Kay Menzies will preside over a Conference of special interest to venereal disease officers of clinics, to hospital almoners, and to all concerned in the problem of securing the maximum efficiency of the venereal disease clinic. This Conference will be preceded in the morning by a display of the propaganda films. Colonel L. W. Harrison will open the discussion from the point of view of the clinical officer; Dr. J. J. Butterworth, county medical officer of health for Lancashire, will deal with the administrative aspect; Dr. Margaret Rorke will be in a position to give the experiences of the women's clinics, and it is hoped that these British speakers will be supplemented by representatives from overseas. The position of the general practitioner in the anti-venereal disease schemes will be considered on May 15th, when a display of technical medical films will also be given. Mr. E. B. Turner will preside over this section. Mr. Amery, late Parliamentary Secretary to the Colonial Office, will preside over the special section devoted to the consideration of Imperial questions. The names of the speakers in this section are not yet to hand, but the Governments and the medical departments of the Dominions and Crown Colonies have all been invited to nominate representatives, and it is hoped that those parts of the Empire where an active programme is in operation will give the workers in the home country the benefit of their experiences. The discussion in the morning of May 16th will be on the Social Hygiene Movement Overseas, and in the afternoon on Methods of Enlightenment for Illiterate Races. Owing to the uncertainty of the political situation, it has not been possible to ascertain whether this Congress can be included as part of the official programme of the work of the Council for the coming year. If it was to be held it was necessary, therefore, for the Council to undertake the arrangements in their capacity as a voluntary organisation. The subjects under discussion are of such outstanding importance that the opportunity should be taken, it is felt, for an interchange of ideas on Imperial lines.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At an ordinary Council meeting held on Feb. 14th, Sir John Bland-Sutton being in the chair, a report was read from the Court of Examiners respecting candidates found qualified for the diploma of Member, and diplomas were granted to 197 candidates.—A report was read from the Conjoint Examining Board respecting candidates found qualified for the diploma in Ophthalmic Medicine and Surgery, and diplomas were granted jointly with the Royal College of Physicians to 12 candidates mentioned in the report.—It was agreed that the President, Sir John Bland-Sutton, be authorised to act with the President of the Royal College of Physicians as almoner for the fund offered by Lord Atholstan for the cure of tuberculosis, to use the fund at their discretion in assisting research work, or, if necessary, in initiating new lines of work in tuberculosis.—The President reported that a meeting of the Fellows would be held at the College on Thursday, July 3rd, for the election of three Fellows in the vacancies occasioned by the retirement from the Council in rotation of Mr. William F. Haslam, Mr. T. H. Openshaw, and Mr. Raymond Johnson; that notice of the meeting would be given to the Fellows by advertisement and by circular on March 7th, that March 17th would be the last day for the nomination of candidates, and that a voting paper would be sent on April 1st to every Fellow of the College whose address is registered at the College.—The President further reported that the Fellows would be invited to attend a reception to be held from 4–6 P.M. on the same day, and that the annual exhibition of additions to the museum would be open for inspection during that time.

SIR JOHN TWEEDY'S COLLECTION.—A collection of instruments used by the late Sir John Tweedy has been presented by his widow to the museum of the College of Surgeons. The most important are two patterns of optometers, used by Tweedy for estimating the degree of astigmatism and other errors of refraction, and first described in THE LANCET of Oct. 28th, 1876,[1] are interesting additions to the group of instruments actually used by their own designers. These include a Beer's knife presented by Prof. Beer himself to G. J. Guthrie, a set of strabismus instruments used by Guthrie in his practice, a Jaeger's strabismus hook given by Jaeger to White Cooper, and a Tyrell's cataract knife used by its inventor.

[1] See also THE LANCET, April 24th, 1886.

UNIVERSITY OF WALES.—At a recent examination for the Tuberculous Diseases Diploma the following candidate was approved: Johan Fredrik Wicht.

THE Minister of Agriculture has announced his intention to appoint a committee of veterinarian and human pathologists to frame a scheme for investigating the causes of foot-and-mouth disease and the possibility of creating immunity for cattle.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The Morison lectures will be delivered by Dr. John Thomson within the Hall of the College, 9, Queen-street, Edinburgh, on Monday, Wednesday, and Friday, March 3rd, 5th, and 7th, at 5 P.M. The subject of the lectures will be the Symptoms, Diagnosis, and Treatment of Mental Defect during Infancy and Early Childhood.

A DINNER of the Royal College of Physicians of Edinburgh was held in the hall of the College, 9, Queen-street, on Feb. 15th.

MANCHESTER CLINICAL SOCIETY.—On Thursday, Feb. 28th, at 4.30 P.M., Sir Thomas Horder will lecture on Medicine and Old Ethics in the Medical Society's Library.

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY.—A special meeting of the society will be held at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W., on March 5th, at 4.30 P.M., when a discussion on the Treatment of Tropical Disease by Waters and Baths will be opened by Dr. Pierret, of La Bourboule, France. All interested are invited to attend.

ANTI-TUBERCULOSIS CAMPAIGN IN CANADA.—It is announced that Lord Atholstan has offered to coöperate with the Government in a campaign against tuberculosis, and proposes to contribute £100,000 towards the cost. His suggestion is that in the first place measures should be taken in other districts on the lines of the Framingham experiment.

UNIVERSITY OF PARIS.—A special practical revision course has been instituted by the Faculty of Medicine at the Medical Clinic of the Hôtel-Dieu on modern methods in clinical work and the application of a current laboratory technique in diagnosis. The course of 35 lectures and demonstrations, which will be conducted in French, commences on Monday, April 7th, and continues till April 18th, under the direction of Prof. Maurice Villaret, assisted by many collaborators. The fee is 150 francs, and the course is open to French and foreign medical men. A full programme may be obtained from the Secretary of the Faculty of Medicine at the University.

THE PRICE OF INSULIN.—The Medical Research Council announce that the principal firms engaged in the manufacture of insulin in this country have arranged to reduce the retail price from 12*s.* 6*d.* to 6*s.* 8*d.* per bottle of 100 units, the change to take effect on Feb. 25th. It will be remembered that the original price in April, 1923, was 25*s.*, and that this was reduced to 17*s.* 6*d.* in July. A gradual increase of 40 per cent. in the strength of the unit then followed, and on Jan. 1st, 1924, the price of 100 revised units was fixed at 12*s.* 6*d.* After less than a year's experience of large scale production the manufacturers have thus found it possible to reduce the original price by nearly three-fourths nominally, and by four-fifths relatively to the actual strength of the product. The new price is below the most recent retail price in America of which information has been received. The Council's announcement concludes: "It may be added that the recently described method of extracting insulin without the use of alcohol has not yet reached the stage of commercial application. In view of the difference between laboratory and large scale methods and of the efficiency to which the alcohol process has now been brought commercially, it must remain uncertain for some time to come whether or not further reductions in price are to be expected from any change of method in this direction."

We are informed by Messrs. Burroughs, Wellcome and Co., who produce the "Wellcome" brand insulin, that their scientific and technical workers have been successful both in improving the yield of insulin from the raw material and in raising the standard of purity. There have been no dramatic discoveries but a series of technical improvements, each step contributing its share to economy in preparation and purity of the product.

Messrs. The British Drug Houses, Ltd., writing on behalf of Messrs. Allen and Hanburys Ltd. and themselves, announce that progressive large-scale manufacture has enabled their hopes of lower cost of production to be realised, and the benefit is to be handed on to the public, this being the third reduction in the price of insulin "A.B." brand since manufacture was begun just over a year ago.

THE Swiney Prize for 1924 has been awarded by the Royal College of Physicians and the Royal Society of Arts to Sir Paul Vinogradoff, F.B.A., Corpus Professor of Jurisprudence in the University of Oxford, for his work, "Outlines of Historical Jurisprudence." The prize consists of a cup, the value of which is £100, and a cheque for £100. It is awarded every fifth year to the author of the best work on jurisprudence.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The Royal Northern Hospital has arranged in conjunction with the Central London Ophthalmic Hospital, the North-Eastern Fever Hospital, and the Royal Chest Hospital, for a two weeks' intensive course from March 3rd to March 15th. It will include demonstrations of clinical methods and cases, lecture-demonstrations, and work in all departments of the hospital from 10.30 A.M. each day. Further particulars, with copies of the complete syllabus, can be obtained on application to the Secretary to the Fellowship of Medicine. A further special course in gynæcology will be given by members of the staff at the Chelsea Hospital for Women from March 3rd to March 28th. The course will consist of lectures and clinical demonstrations in the wards and out-patient department, and in most instances the lectures will be preceded by demonstrations of cases in the out-patient department or by operations in the theatre. A series of lectures and demonstrations in psychological medicine will be given by Dr. J. G. Porter Phillips and Dr. Thomas Beaton at Bethlem Royal Hospital, on Thursdays and Saturdays, at 11 A.M. The subjects of the lectures are given in the syllabus, which is now available. A series of six lecture-demonstrations dealing with recent advances in medical electrical treatment will be given by Dr. C. B. Heald, at the Royal Free Hospital, on Wednesdays, at 5.30 P.M., from March 5th to April 9th. A course on diseases of children, arranged by the Royal Waterloo Hospital for Children and Women, will be held from March 17th to April 5th. The various aspects of children's diseases will be dealt with by members of the staff by means of lecture-demonstrations, ward work, out-patient cliniques, operations, &c. At the end of March a course in ophthalmology will be given at the Royal Westminster Ophthalmic Hospital, details of which will be announced later. Copies of the syllabus with full particulars regarding any of the foregoing courses can be obtained on application to the Secretary of the Fellowship of Medicine, 1, Wimpole-street, London, W. 1.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. (short service) A. C. Esmonde is transferred to the Permanent List.

Surg. Lt. G. L. Stanley is allowed to withdraw with a gratuity.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majs. retire on ret. pay: A. E. B. Wood (granted the rank of Lt.-Col.), H. T. Stack, D. P. Johnstone (secd. Staff, India).

The undermentioned Capts. to be Majs.: A. G. Biggam, R. K. Mallam, D. T. M. Large, W. W. Pratt, A. Hood (Temp. Maj.), E. A. Strachan, C. J. Blaikie, J. H. M. Frobisher, W. B. Stevenson, D. T. Richardson, C. M. Ingoldby, G. A. Blake, (Bt. Maj.), C. J. H. Little, S. J. Barry (Prov.), R. W. Vint, H. W. L. Allott (Prov.), E. P. Allman-Smith.

Capt. G. E. MacAlevey is secd. for service with the Egyptian Army.

Temp. Capt. D. S. Taylor relinquishes his commn. (granted the rank of Maj.).

TERRITORIAL ARMY.

Lt.-Col. G. W. Miller, from R.A.M.C.T.A., to be Col. and Asst. Director of Medical Services, 51st (High.) Divn. T.A., vice Col. F. Kelly, vacated.

Capt. J. D'A. Champney, R.A.M.C., to be Divl. Adjt., 53rd (Welsh) Div., vice Maj. M. White, R.A.M.C., vacated.

ROYAL AIR FORCE.

J. J. Clarke is granted a short service commission as a Flight Lt.

Flight Lt. B. F. Beatson is promoted to rank of Squadron Leader on completion of ten years' service.

INDIAN MEDICAL SERVICE.

Lt.-Col. A. N. Fleming to be Col.

Dwarka Prasad Bhargava to be Temp. Capt.; Muneeh-ud Din Ninhas, Asa Nand Narang, and Lachhman Das Khatri to be Temp. Lt.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 13TH.

Insurance Act Medical Service.

Sir KINGSLEY WOOD asked the Prime Minister whether he proposed to advise the setting up of a Royal Commission to investigate the medical service under the National Insurance Act and kindred matters.—Mr. RAMSAY MACDONALD replied: Perhaps the hon. Member will be good enough to repeat his question this day week, when I hope to be in a position to reply to it.

Remuneration of Panel Practitioners.

Sir KINGSLEY WOOD asked the Minister of Health whether he had received the report of the committee of inquiry appointed to consider the remuneration to be paid to national health insurance practitioners; and what steps he proposed to take in the matter.—Mr. WHEATLEY replied: The recommendations of the Court of Inquiry have already been published, but I am not at this stage prepared to anticipate the provisions of any legislation required to give effect to these recommendations.

THURSDAY, FEB. 14TH.

The Lease of Bellahouston Hospital.

Mr. MURRAY asked the Minister of Pensions if the Ministry intended to close Bellahouston military hospital, Glasgow; and, if so, what arrangements were being made to provide treatment for ex-Service men at present accommodated at Bellahouston or who attended there for treatment and advice.—Mr. F. O. ROBERTS replied: I have no intention of closing Bellahouston Hospital if it can be avoided, and I am hoping that it may be found practicable to come to an arrangement with the Glasgow Corporation, who own the land upon which the hospital stands, with a view to an extension of the expiring lease.

Treatment Allowances.

Mr. KEDWARD asked the Minister of Pensions the number of ex-Service pensioners who attended hospital during January this year as out-patients and received treatment allowances, and the number of such out-patients in receipt of treatment allowances during the same month of the years 1921, 1922, and 1923; if he was aware that very grave hardship was inflicted on large numbers of ex-Service pensioners who had been under treatment in Ministry of Pensions hospitals owing to the termination of treatment allowances immediately on their discharge from hospital; whether he would arrange for treatment allowances to be paid to those men for at least one week after discharge; and was he aware that an organisation upheld by voluntary contributions—namely, the British Red Cross—very often had to help in such cases to prevent privation and suffering to such men and their families.—Mr. F. O. ROBERTS replied: I regret that figures for the precise periods mentioned are not available, but I am circulating information which will, I think, serve the hon. Member's purpose. The point raised in the latter part of the question has recently been inquired into by a departmental committee, who have recommended that my department and the Ministry of Health should jointly consider what steps can properly be taken in the circumstances mentioned. The whole matter is receiving my consideration. The following are the particulars referred to:

—	No. undergoing out-patient treatment.		Total.
	With allowances.	Without allowances.	
During Dec., 1923 ..	10,259	26,956	37,215
During Dec., 1922 ..	19,833	51,042	70,875
During May, 1922* ..	27,701	60,733	88,434

* The earliest date for which records are available.

Beckett's Park Hospital, Leeds.

Sir GERVASE BECKETT asked the Minister of Pensions whether a decision had been arrived at as to the closing of the military hospital at Beckett's Park, Leeds; whether he was aware of the hardship and inconvenience to the many hundreds of ex-Service patients attached to the hospital; whether he had considered the great expense entailed upon removal elsewhere and the loss of the large sums laid out upon the present buildings; and whether he was aware that the proposal had excited great apprehension in the minds of the patients and indignation amongst their relatives and the people of Yorkshire generally.—Mr. F. O. ROBERTS replied: This building is held by the Ministry on a lease which will expire next August. I am anxious to obtain a renewal, and negotiations to that end are proceeding.

Ex-Service Men and Tuberculosis.

Mr. SHORT asked the Minister of Pensions the number of ex-Service men suffering from tuberculosis who had been deprived of their pensions for one reason or another.—Mr. F. O. ROBERTS replied: Since July, 1922, the earliest date available, 900 awards in respect of pulmonary tuberculosis have been discontinued out of a total of 38,000 awards in payment for that disability.

Mr. SHORT asked the Minister of Pensions whether he was aware of the large number of ex-Service men suffering from pulmonary tuberculosis who had been deprived of their pensions on the ground that the disability had ceased but whose health and physical condition did not permit them to follow any but exceptional occupations which were most difficult to obtain, who could not withstand varying weather conditions; and, if so, what action, if any, did he propose to take to assist such cases.—Mr. F. O. ROBERTS replied: I am aware of this difficulty, which will have the earliest possible consideration. I shall, of course, be glad to look into any particular case which my hon. friend may have in mind.

The Feeding of School-children.

Mr. MARLEY asked the President of the Board of Education whether it was his intention to continue the system known as rationing, by which the sum available to be divided among all the local education authorities who were prepared to undertake to provide meals for school-children was strictly limited, with the consequence that thousands of children had to go to school insufficiently fed.—Mr. C. TREVELYAN replied: I do not propose to retain a specific limit on the expenditure of local education authorities on the provision of meals for school-children for the calculation of grant. At the same time, I rely on local education authorities to exercise due economy and care in the administration of this service.

The White Lead Convention.

Mr. GRAHAM WHITE asked the Minister of Labour if the difficulties which prevented the ratification of the convention on the use of white lead in paint had yet been removed; and if it was now the intention of the Government to agree to the ratification of this convention.—Mr. T. SHAW replied: I have been in consultation with my right hon. friend, the Home Secretary. The question is under consideration by His Majesty's Government, and the decision will be announced as soon as possible.

Use of Tuberculin by Farmers.

Mr. SPERO asked the Minister of Health whether he was aware that a number of farmers injected their herds with tuberculin and that such injections had the effect of nullifying the veterinary inspectors' tests; and whether he would restrict the sale of tuberculin to qualified medical men and veterinary surgeons.—Mr. BUXTON replied: I am aware that a tuberculous animal which has been subjected to the tuberculin test will not normally react again to this test for a considerable time, and that an unscrupulous stock-owner therefore might use this to enable him to pass a tuberculous animal for a healthy one. I have no reason to think, however, that this practice is carried on to any appreciable extent. Many farmers use tuberculin for the legitimate purpose of testing their herds, and I am not prepared at present to place obstacles in their way by adopting the suggestion contained in the second part of the question.

Infant Welfare Centres.

Mr. BLACK asked the Minister of Health whether he was willing to sanction the establishment of infant welfare centres under the supervision of the county councils, and with the usual Government grants wherever efficient voluntary services were offered for the proper conduct thereof.—Mr. WHEATLEY replied: I am prepared to consider where additional centres are needed for proposals for the establishment of infant welfare centres by local authorities, or by voluntary bodies acting in coöperation with local authorities, and to pay the usual grants-in-aid on approved expenditure.

Hospital Treatment for Tuberculosis.

Mr. BLACK asked the Minister of Health whether he was prepared to sanction the provision of hospital treatment for advanced cases of tuberculosis as proposed by the county of Leicester; and, if not, whether he had considered the futility of providing treatment for many early cases of consumption whose disease could be directly traced to infection from persons in an advanced state of tuberculosis who were compelled to remain in crowded houses until removed by death.—Mr. WHEATLEY replied: The question of the provision of hospital treatment for advanced cases of tuberculosis in Leicestershire is receiving my consideration in connexion with communications which have taken place between my department and the county council as to the

most suitable means of effecting such provision. The second part of the question does not, therefore, arise.

FRIDAY, FEB. 15TH.

Tuberculosis in Cattle.

Sir ROBERT ASKE asked the Minister of Health whether his attention had been called to the report of the veterinary inspector of Newcastle-upon-Tyne, upon his examination of cattle sent in for slaughter for food, showing that of cattle externally sound over 74 per cent. were in fact suffering from tuberculosis, and to the representations of the city council with reference thereto; and whether the Government would introduce at an early date legislation for protecting infant life against the risks arising from the distribution of milk infected with tubercle bacilli.—Mr. WHEATLEY replied: Yes, sir. My attention has been drawn to the report of the Newcastle-upon-Tyne veterinary inspector, and to the representations of the city council with reference thereto. With regard to the second part of the question, I would refer the hon. Member to the Milk and Dairies (Consolidation) Act, 1915, the operation of which is postponed till Sept. 1st, 1925, by the Milk and Dairies (Amendment) Act, 1922.

MONDAY, FEB. 18TH.

The "Humane Killer."

Sir HARRY BRITTAIN asked the Minister of Agriculture whether he would do what he could to expedite the compulsory introduction of the humane killer into this country.—Mr. WHEATLEY, who replied, said: The matter will receive the consideration of the Government. As the hon. Member was informed in July last, any local authority can make the use of the "humane killer" compulsory in its own area, and over 100, including the L.C.C., have already done so.

Deaths from Infectious Diseases.

Mr. BROAD asked the Minister of Health how many deaths were registered in 1923 as due to small-pox, measles, influenza, pneumonia, diphtheria, and scarlet fever.—Mr. WHEATLEY replied: The following are the provisional figures of the deaths registered in 1923 as due to these diseases (except pneumonia): small-pox, 7; measles, 5200; influenza, 8371; diphtheria, 2674; scarlet fever, 971. The final figures, including the number of deaths from pneumonia, will not be available until the end of the present quarter.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Feb. 25th.

ODONTOLOGY: at 8 P.M.
Casual Communication:
Mr. W. W. James: Hæmorrhage following Tooth Extraction.
Adjourned Discussion on Pyorrhœa, to be reopened by Mr. J. G. Turner.

Tuesday, Feb. 26th.

MEDICINE, NEUROLOGY, OPHTHALMOLOGY, OTOLOGY } at 5.30 P.M.
Joint Discussion on Vertigo.
Dr. R. Hutchison (President of the Section of Medicine) in the chair.
Speakers: Sir Humphry Rolleston, Dr. Gordon Holmes, Mr. Sydney Scott, and Mr. J. Herbert Fisher.

Wednesday, Feb. 27th.

COMPARATIVE MEDICINE: at 5 P.M.
Paper:
Dr. T. W. M. Cameron: The Pig and Human Diseases.
Specimens:
Dr. R. T. Leiper and Dr. T. W. M. Cameron will show a series of specimens illustrating Host Reactions to Helminth Infections.

Thursday, Feb. 28th.

UROLOGY: at 8.30 P.M.
Papers:
Dr. W. MacAdam: Cholesterol Content of Blood in Relation to Genito-urinary Sepsis.
Mr. H. Winsbury White: Subparietal Injury of the Kidney.

Friday, Feb. 29th.

The next Social Evening will be held on Friday, Feb. 29th, when Fellows, Members of Sections, Associates, and their friends will be received by the President, Sir William Hale-White, and Lady Hale-White, at 8.30 P.M.
Dr. Arnold Chaplin will give, at 9 P.M., a brief discourse on Famous Medical Men of the Eighteenth Century, with lantern illustrations of portraits.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Feb. 25th.—8.30 P.M., Discussion on the Treatment of Fibroids of the Uterus. To be introduced by Dr. Cuthbert Lockyer, followed by Sir George Blacker, Mr. Thos. G. Stevens, Dr. H. Williamson, Mr. Beckwith Whitehouse, Dr. N. S. Finzi, Mr. J. P. Hedley, Dr. Douglas Webster, and others.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.
FRIDAY, Feb. 29th.—8.30 P.M., Discussion on the Instruction of the Medical Profession and the Lay Public with respect to the Facilities provided for the Diagnosis and Treatment of Venereal Disease. The following will take part: Colonel L. W. Harrison, Dr. F. Kay Menzies, Mr. Frank Kidd, Mr. E. B. Turner, Prof. Winifred Cullis, Mrs. Neville Rolfe.

ROYAL SOCIETY OF ARTS, John-street, Adelphi.
WEDNESDAY, Feb. 27th.—8 P.M., Dr. Charles F. Myers: The Use of Psychological Tests in the Selection of a Vocation.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Feb. 25th, to FRIDAY, Feb. 29th.—Combined Course on Diseases of Children. Clinical Demonstrations and Lectures from 10 A.M. to 4.30 P.M. daily, including the CHILDREN'S CLINIC (WESTERN GENERAL DISPENSARY), the PADDINGTON GREEN CHILDREN'S HOSPITAL, the VICTORIA HOSPITAL FOR CHILDREN, and the ROYAL WATERLOO HOSPITAL.—LONDON LOCK HOSPITAL. Clinical work daily. Lectures at Dean-street as follows: Mon., 5 P.M., Mr. Gibbs: Ante-natal and Post-natal Treatment of Syphilis; Tues., 2.30 P.M., Mr. McDonagh: Microscopic Demonstrations of Leucocytozoon Syphilidis; Thurs., 4.30 P.M., Mr. Abel: Treatment of Chronic Gonorrhœa in the Male.—LONDON SCHOOL OF TROPICAL MEDICINE. Tues. and Thurs., 2 P.M., Special Clinical Demonstrations.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.
POST-GRADUATE COURSE: FEBRUARY–MARCH, 1924.
CLINICAL LECTURES AND DEMONSTRATIONS.
MONDAY, Feb. 25th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Spinal Cord Diseases: Dr. James Taylor.
TUESDAY, Feb. 26th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Demonstration of Specimens of Cerebral and Spinal Tumours: Dr. Greenfield.
THURSDAY, Feb. 28th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Intracranial Complications of Middle-ear Disease: Mr. Just.
FRIDAY, Feb. 29th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Surgery of Spinal Cord: Mr. Sargent.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.
MONDAY, Feb. 25th.—12 noon, Poliomyelitis and Lethargic Encephalitis: Dr. J. G. Greenfield.
The fee for the Course, including Pathology, is £5 5s. For those who hold Perpetual Tickets the fee is £3 3s.

COURSE OF LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.
WEDNESDAY, Feb. 27th.—12 noon, Cerebellum: Dr. Kinnier Wilson.
THURSDAY, Feb. 28th.—12 noon, Mesencephalon and Corpus Striatum: Dr. Kinnier Wilson.
The fee for this Course will be £2 2s.
Dr. F. M. R. Walshe will give A COURSE OF EIGHT CLINICAL DEMONSTRATIONS, CHIEFLY ON METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, in the Wards at 10 A.M., every Wednesday and Thursday during February. The numbers attending the Course will be limited. Fee £2 2s.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE NEUROLOGY OF THE EYES.
WEDNESDAY, Feb. 27th.—3.30 P.M., Optic Atrophy: Mr. Leslie Paton.
The fee for this Course alone is £5 5s. If taken in conjunction with the general Post-Graduate Course the fee is £3 3s. All applications should be sent to the Secretary, Medical School.
Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.
Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.
J. G. GREENFIELD, Dean of Medical School.

ST. THOMAS'S HOSPITAL, Albert Embankment, S.W.
(In the Governors' Hall.)
THURSDAY, Feb. 28th.—5 P.M., Dr. J. A. Murray: Cancer (Second Lecture).

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
TUESDAY, Feb. 26th.—5 P.M., Dr. MacCormac: Desensitisation.
THURSDAY.—5 P.M., Dr. Griffith: Bullous Dermatoses.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.
THURSDAY, Feb. 28th.—4 P.M., Mr. Barrington-Ward: Appendicitis.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Feb. 25th.—10 A.M., Surgical Registrar: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards.
TUESDAY, 10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.
WEDNESDAY.—12.15 A.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Dr. Pernet: Skin Dept.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Dr. Simson: Gynæcological Demonstration. 2 P.M., Mr. Bishop Harman: Eye Dept.
FRIDAY.—10.30 A.M., Dr. Pritchard: Medical Wards. 12 noon, Mr. Endean: Venereal Diseases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
THURSDAY, Feb. 28th.—5 P.M., Mr. L. G. Phillips: Infant Feeding.

CANCER HOSPITAL, Kensington, S.W.
WEDNESDAY, Feb. 27th.—4.30 P.M., Dr. C. A. Joll: Malignant Disease of the Thyroid Gland.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
TUESDAY, Feb. 26th.—4.15 P.M., Mr. C. Roberts: Surgical Complications of Diabetes.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE (at Whitworth-street West Branch).
FRIDAY, Feb. 29th.—4.30 P.M., Dr. J. F. Ward: The Internal Secretions in Infancy and Childhood.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES.
THURSDAY, Feb. 28th.—4.30 P.M., Mr. A. C. Magian: The Operative Treatment of Prolapsed Ovaries.

SALFORD ROYAL HOSPITAL LECTURES.
THURSDAY, Feb. 28th.—4.30 P.M., Dr. A. C. Sturrock: The Nervous Manifestation of Rheumatism.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)
MONDAY, Feb. 25th.—(At the Children's Hospital.) Dr. Murray Bligh: Rickets.
TUESDAY.—(At the Southern Hospital.) Mr. G. P. Newbolt: Surgical Cases.
WEDNESDAY.—(At the Northern Hospital.) Mr. McMurray: Surgical Condition of the Hip-joint.
THURSDAY.—(At the Stanley Hospital.) Dr. Gullan: Aortic Valvular Disease.
FRIDAY.—(At the Royal Infirmary). Mr. Woolfenden: Surgical Cases.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES.
TUESDAY, Feb. 26th.—(At the Royal Hospital.) 3.30 P.M., Dr. Mould: Dementia Præcox.
FRIDAY.—(At the Royal Infirmary.) 3.30 P.M., Prof. Mellanby: Some Recent Discoveries in Therapeutics.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Feb. 27th.—4 P.M., Dr. A. C. Inman: The Rôle of the Laboratory in the Tuberculosis Problem.

Appointments.

BLOOMFIELD, Miss A., M.D. Edin., F.R.C.S. Eng., has been appointed Assistant Surgeon to the South London Hospital for Women.
BORTHWICK, G. A., M.D., Ch.B. Edin., Medical Officer to the Port of Plymouth.
PEMBERTON, H. S., M.B., Ch.B. Liverp., M.R.C.P.Lond., Honorary Physician to the David Lewis Northern Hospital, Liverpool.
SIMPSON, J. V. A., M.D. Lond., D.P.H. Camb., Deputy Medical Officer of Health, Torquay.
WATSON, F. H., M.B., Ch.B. St. And., Medical Officer in Charge of the Maternity Hospital and Clinics, Portsmouth.
Certifying Surgeons under the Factory and Workshop Acts: PORTER, J. H., M.R.C.S., L.R.C.P. Lond. (Littlehampton); KENDALL, G. M. (Epsom).

Vacancies.

For further information refer to the advertisement columns.
Birmingham General Hospital.—Director of V.D. Dept. £600.
Birmingham, Highbury, Uffculme and Sorrento Hospitals.—Med. Supt. £800.
Board of Control. Victoria-street, S.W.—Inspectors. £500 and £400 respectively.
Bristol, Cossham Memorial Hospital, Kingswood.—H.S. £150.
Bristol General Hospital.—Two H.P.'s, H.S., Res. Obstet. O., and Cas. H.S. Each £125.
Canterbury, Kent and Canterbury Hospital.—Res. M.O. £175.
East Suffolk Administrative County.—Asst. Tub. O. £500.
Edinburgh, Chalmers' Hospital.—Surg. O.
Elizabeth Garrett Anderson Hospital, Euston-road.—Hon. Clin. Assts. Also Asst. M.O., V.D. Dept. £1 1s. per attendance.
Evelina Hospital for Children, Southwark, S.E.—Hon. Phys.
Finsbury Metropolitan Borough.—Asst. M.O.H. £600.
Halifax Royal Infirmary.—Hon. Ophth. S. and Hon. Radiologist.
Hertford County Hospital.—Hon. Asst. S.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Ear, Nose, and Throat S.
Hull Royal Infirmary.—Asst. H.S. £150.
Leeds City.—Asst. M.O.H. £750.
Leicester City Education Committee.—Asst. Sch. M.O. £600.
Leicester Royal Infirmary.—H.S. £150.
Manchester, Ancoats Hospital.—Two H.S.'s. £100.
Manchester Corporation.—Asst. Tub. O. £621.
Melton, Suffolk, St. Audry's Hospital.—Med. Supt. £1000.
Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—Asst. S. H.S. £150. Also Clin. Assts.
National Hospital for Diseases of the Heart, Westmoreland-street, W.—Res. M.O. £150.
National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. P.
Newcastle-upon-Tyne, University of Durham College of Medicine.—Lectureship on Med. Jurisprudence.
Nottingham Children's Hospital.—Res. H.P. £150.
Portsmouth Royal Hospital.—Sen. H.S. £200. Also Asst. H.S. £150.
Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Two Asst. Res. M.O.'s. Each £80. Also Sen. R.M.O. £100.
Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—H.P. and H.S. Each £100.
Royal General Dispensary, Bartholomew Close, E.C.—R.M.O. £175.
St. Pancras Dispensary, 39, Oakley-square, N.W.—Hon. Ophth. S.
St. Thomas's Hospital.—P. Also Ophth. S.
Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. £150.
South London Hospital for Women, South Side, Clapham Common, S.W.—Three H.S.'s and one H.P. Each £50.
University College Hospital Medical School.—Graham Scholarship in Pathology.
Wakefield, West Riding of Yorks.—Temporary M.O. 10 guineas.
West London Hospital, Hammersmith-road, W.—One H.P. and Two H.S.'s. Each £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Dinas Mawddwy, Merioneth; Rocester, Staffs.
The Secretary of State for the Home Department proposes to appoint an additional Medical Referee under the Workmen's Compensation Act for the County of Orkney. Applications should reach the Private Secretary, Scottish Office, not later than March 8th.
The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, for the Districts of the County Courts of Barnard Castle, Darlington, and Richmond (Circuit No. 2); and Leyburn and Northallerton (Circuit No. 15). Application for the posts should be addressed to the Private Secretary, Home Office, and should reach him not later than March 8th.

Births, Marriages, and Deaths.

BIRTHS.

BAKER.—On Feb. 9th, at Camden-road, the wife of H. Searle Baker, M.R.C.S., L.R.C.P., of a son.
BRODRIBB.—On Feb. 10th, at St. Leonards-on-Sea, the wife of Arthur W. Brodribb, M.A., M.B. Oxf., M.R.C.S., of a son.

MARRIAGES.

DAVIES—ROSS.—On Feb. 12th, at All Saints' Church, Wigston, Leicester, John Harold Twiston Davies, B.A. Cantab., M.R.C.S., to Isabel, daughter of Mr. and Mrs. S. A. Ross, of Wigston Magna.
GABRIEL—TYSON.—On Feb. 14th, at St. Margaret's Church, Lowestoft, by the Rev. G. N. Selby-Lowndes, assisted by the Rev. E. C. Morgan (Rector of the Parish), William Bashall Gabriel, M.S., F.R.C.S., younger son of the late E. E. Gabriel and Mrs. Gabriel, Oulton Broad, Suffolk, to Evelyn Maud, daughter of Wilson Tyson, M.D., F.R.C.S., and Mrs. Tyson, Lowestoft.

DEATHS.

BLATHERWICK.—On Feb. 12th, at Coleherne-court, S.W., Henry Blatherwick, M.R.C.S., L.R.C.P., aged 65 years.
CURREY.—On Feb. 16th, at Swarthbeck Point, Ullswater, Robert Henry Currey, F.R.C.S. Edin., M.R.C.S. Eng.
GREEN.—On Feb. 12th, Herbert Melvill Green, M.D., of Clarges-street, W. aged 55 years.
HANNAH.—On Feb. 16th, at Woodlands, Ashton-in-Makerfield, Lancashire, in her 81st year, Elizabeth, widow of the late Nathan Hannah, L.R.C.P. Edin., L.F.P.S. Glasg., M.O.H.
JOHNSTON.—On Jan. 23rd, at Sidney, Vancouver Island, British Columbia, George David Johnston, M.R.C.S., L.R.C.P. Lond., in his 72nd year.
JOYCE.—On Feb. 12th, Thomas Joyce, M.R.C.S., at Wood Knowle, Mayfield, Sussex, in his 90th year.
MARDER.—On Feb. 3rd, at Burley, Lyme Regis, Edward Swan Marder, Major, late R.A.M.C., aged 64 years.
THOMSON.—On Feb. 13th, at Ivy Dene, Sweyn-road, Margate, Robert Thomson, M.D., M.Ch., aged 62 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

DOCTORS* AND ADVERTISING.

BY HAROLD D. L. SPENCE, M.D., M.CH. ONT., M.R.C.S. ENG.,
LATE CHIEF ASSISTANT, SKIN DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

As a profession we express, or there is expressed for us, a certain abstract abhorrence of advertising or advertisement; but a serious difficulty is encountered immediately we proceed to determine just what constitutes advertising.

We know that it has been contended that a doctor named in the Court Circular column of a daily newspaper as being a relative of a bride was advertising, as these notices are charged at so much per line—but it is inconceivable that such an item would be calculated to bring patients to the doctor's door, the ideas being in no way associated. Yet the statement in the more widely read news columns of the same newspaper that Sir Jupiter Pluvius, the astronomer, is progressing satisfactorily after an operation for appendicitis performed by Mr. Joshua Whatnoodle, the very eminent surgeon, is not to be mistaken for advertising, being either news or a gratuitous tribute to worth and achievement. Here is surely what undergraduates term a distinction without a difference—since advertising value is measured by results; and in the commercial field, if I may be permitted to make the comparison, a free advertisement, possessing a unique impersonal quality in the guise of reading matter, may prove invaluable whereas the most expensive space may be utterly wasted.

On the same occasion reference is understood to have been made to the "bulletin," and here complainant was on firmer ground; for this must be the most useful form of professional publicity. The names appended reach millions of newspaper readers in the most favourable setting, the nature of the illness is known, and it seems a reasonable assumption that a wealthy or prominent patient will secure the ablest professional attention in the circumstances. Again we are loftily told that this too is not advertising. Assuming that this is so it is strange that in my scrap-book, containing examples of every conceivable kind of professional publicity from the timid personal item to raging propaganda, I find nothing approximating to the following hypothetical signed bulletin: "Lord Algernon Debrett who was operated upon yesterday for appendicitis became gradually weaker during the afternoon and expired early to-day."

It may be permissible to suggest that whilst there are exceedingly few of us who really object to the publicity which it denotes, there is practical unanimity in the dislike of the unpleasant word *advertising*, which as medically misused has become a term of opprobrium, with a confused suggestion of sky-signs, cure-alls, slogans, and registered trade-marks. Professional publicity has always existed in one form or another. If the modern newspaper is the most important, it is by no means the only medium of publicity employed by the profession: and unless the character of the act is determined less by its own intrinsic quality than by the number in the audience to which it is directed, it is clear that we can as little attack one form of publicity whilst conveniently ignoring the others as we can condemn in one individual what we condone in another—for to do so is to justify a suspicion that our attitude towards publicity is somewhat complex.

The layman, knowing little of the prejudices and rivalries apparently inseparable from so individualistic a calling as our own, is at a loss to understand the good friend who seems threatened with imminent apoplexy upon observing that a colleague is given prominence in the day's news or is pictured with other interesting people in the illustrated page. No one is more jealous of reputation than the barrister or clergyman, but it is open to either to contribute freely to lay publications, and it is never suggested that the standing of the great craft of the law or of the noblest of professions is lowered in consequence. An Ethical Committee very commonly assumes an authority it by no means possesses; and since amongst its members are inevitably those who are apprehensive concerning any departure that seems novel or calculated to disturb the uneventful progress of a placid or semi-vegetative existence it hastens to label as improper anything of which its members personally disapprove. As a matter of fact, the doctor possesses a complete and unassailable right, both legal and moral, to secure publicity in certain ways if he so desires, equally with the barrister and clergyman, provided always that he is careful to respect the rules of professional honour; and once we recognise this elementary truth it becomes no longer necessary to infer, with polite dissimulation, that well-written articles or synopses of lectures complete with name, degrees, and studio-portrait appear in a newspaper accidentally or represent a reluctant capitulation to the persistent importunacy of editorial perseverance or pragmatism.

Long ago John Stuart Mill wrote: "There has been much complaint of late years, both in the world of trade and that of intellect, of quackery, and especially of puffing; but nobody seems to have remarked, that these are the inevitable fruits of immense competition, of a state of society where any voice not pitched in an exaggerated key is lost in the hubbub."

It is impossible to view with complacency the employment by professional men of undignified or blatant methods of publicity, for improper methods not only recoil upon the individual but bring the whole profession into contempt. Equally indefensible, however, is the attitude of the few who would have the doctor, following a large capital outlay for education, premises, and equipment, virtually immure himself within brick walls after the manner of monks and ascetics in the Middle Ages. There is a "mean" here as in all things, and it would be well to recognise this quite frankly. Regulations which repress are always broken, and particularly is this so where it happens that, contrary to the Euclidean philosophy, the part may be greater than the whole.

If the intelligent professional advertiser benefits himself he also benefits the profession. Putting it on the lowest basis, every patient treated by a fully trained and competent practitioner represents an economic saving to the community as well as a score at the expense of lightning cures or osteopathic, spondyloplastic, oscillo-clastic, or mechano-therapic clap-trap. The extra-professional advertiser is, however, a very damaging competitor.

Some ten million pounds was spent last year in this country for patent medicines. I invite readers to judge in what proportions this was due to (*a*) the patient's inability to find the right practitioner or specialist; (*b*) the professional habit of pooh-poohing minor ailments, real enough to the patient, and (*c*) the tendency of many doctors to play the pharmaceutical manufacturer's game and recommend a proprietary mixture or pseudo-scientific nostrum, whether through laziness, carelessness, or ignorance of the contents of that excellent work, the British Pharmacopœia.

The General Medical Council have indicated that they hold in special disfavour publicity which tends to disparage the work or abilities of professional colleagues, and a reference to the pages of my scrap-book quickly discloses examples which seem, either directly or through the inference conveyed, to fall foul of this injunction. It is also very interesting to note through contrasts in individual method how practice may be aggressive without raising invidious distinctions or giving rise to the least suggestion of impropriety. The bacteriologist, a complete and unquenchable therapeutic optimist, has long enjoyed a good press; but further, he may distribute his products through the sales organisation of the wholesale chemist, or becoming a "laboratory" join business and profession in a quasi-sanctified union. Thus a liaison is secured with a wider clientèle, using methods which I consider entirely in harmony with correct ethical principle. Let us now compare with this a certain lack of dignity, which we must attribute to the hyperbolic enthusiasm of the descriptive journalist, in the three-quarter column newspaper announcement that a group of "famous doctors" are prepared collectively to supply the "best advice" for a price much less than the individual fees would aggregate, indeed for "a fourth or in some cases a fifth of these sums." Anti-venereal advertising presents unique features, and is at variance with the dictum of the General Medical Council, if only in the unblushing use in lavatory announcements and other literature addressed to the public of the word "expert," perhaps the most abused in our language. If it be questionable form for an individual, whatever his attainments, to describe himself as an "expert" it is equally wrong for two, three, or a half-dozen individuals, constituting the staff of a venereal clinic, to pronounce the word in unison, for this is precisely what it amounts to. Again, those of us who have served for any length of time in venereal hospitals or clinics know that whereas it is the conceit of the attending doctor to increase the attendance on his day, and the *business* of the astute and enterprising caput-counting secretary to increase the attendance on each and every day, it is very often the affair of no one in particular to discover

* For the purposes of this paper the word "doctor" is used in the generic sense understood abroad. It is hoped that nothing written will be construed as referring to any individual, the intention being to present a point of view widely held in a quite impersonal way.

whether a certain patient is or is *not* entitled to free treatment; and so it happens that, the clinic being supported from public funds, the private practitioner is in the extraordinary situation of personally contributing money through taxes towards the support of a clinic, which is not only actively *competing* with him, but is permitted to attract new patients by means which he as an individual is forbidden to employ.

Major abuses of professional etiquette and privilege, including the improper use of advertisement, bear a curiously constant inverse relation to the educational and professional acquirements of the individual, whence it would appear that the most effective method of combating them lies in prophylaxis, through a sustained effort to increase the prestige of the profession, both individual and collective, by raising educational standards. The American Medical Association has demonstrated the useful work that an ably conducted national association with no executive powers can perform in improving the standing of the profession it represents. For twenty years its Council on Education has persevered in a campaign designed to improve the equipment and quality of the American practitioner. So successful has this been that the number of medical colleges has been reduced through the elimination of weaker institutions from 162 to 95, and the students enrolled from 28,142 to 17,432. Of the latter number 94 per cent. attend class "A" schools, requiring before admission two or more years of university attendance and in some cases—e.g., Harvard—a literary degree (B.A.), and conforming in the course of study provided to what is regarded as an "ideal" standard. Endowments have increased in the interval; better hospital relations have been secured; plant, laboratories, and teaching methods continuously improved; and medical education in the United States to-day probably equals, if it does not surpass, that of any other country. Concurrently a very real service has been rendered the profession by its Council on Pharmacy in the systematic investigation of new remedies, and unrelenting war waged against the nostrum evil and towards "cleaning" the advertisement pages not only of the medical but of the lay press, the *Journal* of the American Medical Association itself furnishing a notable example in this particular. I suspect that regular readers of its weekly "Propaganda for Reform" column can be little impressed by colloidal magic, nor are they likely to prescribe greaseless massage cream flavoured with glycerophosphates to be taken internally as a great tonic restorative.

HOUSING STANDARDS: HOW THEY MAY BE RAISED.

A Chadwick public lecture was delivered by Dr. A. K. Chalmers at the Kensington Town Hall on Feb. 15th, Sir James Crichton-Browne being in the chair, and repeated on the 18th at the Goldsmiths' College Lecture Hall, New Cross, Sir William J. Collins presiding. Housing customs in England and Scotland were contrasted, and Dr. Chalmers referred to the initial difficulty in use of terms. A "tenement" in Scotland is usually a building of three or four storeys, with each floor divided into two or three or more "houses"; in England, as a rule, the terms are reversed—the whole building is the "house," and the separate occupancies are the "tenements." As a common term, the house may be regarded as the accommodation required for home and family life. When the house is "made down" to accommodate several families, the primary services—water-supply, drainage, ventilation—originally designed for one family, are all modified and frequently impaired. As a rule the house in England has more rooms than the house in Scotland, but the rooms of the house in Scotland tend to be larger. The one-apartment house is a common feature of Scottish housing. It combines the functions of the living room, scullery, and bedroom. Sculleries were not common in small houses in Scotland until recent housing schemes. After referring to the effect of climate on constructional requirements, the lecturer commented on the early aspects of housing questions and the Chadwick report. He also pointed out the association between indifferent housing, inadequate food, poorly paid labour, and ill-health. Illustrations of association between bad housing and bad health were shown in a series of lantern slides.

Dr. Chalmers dealt with the movement for improving the dwellings of the working classes, showing how the cessation of house building during war years had raised acutely the question of a housing shortage, and led subsequently to a return of the older problem of the improvement of slum areas. Indifferent success had met the efforts to solve the problem in the nineteenth century. As to the question of standards, the Housing Acts and building regulations define these in a degree. The primary requirements of healthy housing are obviously a pure water-supply and an adequate system of refuse removal. Absence of these is commonly associated with other defects in the construction of the house, its design and relationship to other buildings. The Housing Act of 1890 focused and amplified earlier legislation. Building regulations were complementary to the clearance of insanitary areas. Among other purposes they were intended to prevent overbuilding of sites, and to provide free circulation of air and adequate lighting of rooms. The width of the street in relation to height of buildings facing it was an important factor. Efforts to obtain adequate lighting and ventilation of back rooms were detailed. The inflexibility of building regulations was often a drawback, and the desire in New York to adapt them to the needs of particular areas by a system of "districting" showed that this was the case in other countries as well as here. The orientation of streets in relation to available sunlight was an important feature of town-planning. There was an advantage in streets running diagonally with the cardinal points of the compass. Dr. Chalmers concluded by showing how density may be measured, and showed the relative value of floor area and height of ceilings in relation to number of persons per room. Under building regulations the gradual enlargement of the room in houses erected might be noticed. There was improvement in the smaller houses, but the tendency to increase the number of rooms at the expense of the floor area of individual rooms, and especially of the area of sleeping apartments, could not be accepted as final.

"POISONED DAMSELS."

To the Editor of THE LANCET.

SIR,—I am bringing out a 10-volume edition of a collection of Sanskrit stories known as the "Kathā Sarit Sāgara," and they are being fully annotated by myself. In one of these stories we read of a king who, when about to attack another king, first sent spies into the country and also despatched "poisoned damsels." It appears that these "poisoned damsels" were brought up from childhood on the poison of snakes until their whole system became full of poison. So much so that any connexion with them, or sometimes even their kiss would kill a man. Some writers have suggested that this may refer to syphilis. Personally, I do not for a minute think it does, but I would like to know, on the best authority, the earliest date that syphilis has been traced in India. I believe it was introduced by the Portuguese at Goa. Are there any records of poisons of any kind, particularly snake venom, being used to cause death either through the touch or by putting it in food, drink, or clothing?—I am, Sir, yours faithfully,

N. M. PENZER.

12, Clifton-hill, St. John's Wood, N.W., Feb. 18th, 1924.

DANGEROUS DRUG RECORDS.

WE have received specimens of a new edition of the Prescribers' Card, issued by the *Chemist and Druggist* (42, Cannon-street, London, E.C. 4) for the use of medical practitioners in prescribing scheduled dangerous drugs. The information given is concise and complete, while the handy size (7 by 3½ in.) of the card makes it suitable for the desk or pocket. The new edition embodies the changes brought about by the Dangerous Drugs and Poisons (Amendment) Act, 1923, and the Regulations issued since the issue of the first edition in 1921. The cards are supplied in quantities of one dozen at 1*s.* 6*d.* post free.

THE "MANETOR" COOLING-COMPRESS.

THE "Manetor" consists of small perforated discs of a hygroscopic earth which are joined together in the form of a ribbon or other shape for application to the forehead, neck, wrist, and præcordial and other regions of the body. For use it is soaked in water for a minute or two, the superfluous moisture dried off, and the apparatus applied to the skin, the required coldness being produced by evaporation. The apparatus may prove useful in the sick-room so far as it gives relief to the patient—and it is sometimes very difficult to separate what is physical from what is suggestive—but time is necessary to show whether it can take the place of the ice-pack, Leiter's coil, or other apparatus of the kind. Messrs. Norman Patterson and Co., Ltd., 150, Southampton-row, London, W.C., are the manufacturers.

AT the February meeting of the Council of the Society of Members of the Royal College of Surgeons of England Dr. Sidney C. Lawrence was presented with an illuminated address in appreciation of his services as hon. secretary of the Society for the past 15 years.

Intravenous Treatment of Syphilis.—The new preparation, "Flumerin," which was the subject of an article by Dr. W. R. Snodgrass in THE LANCET of Jan. 19th, is supplied by Messrs. Hynson, Westcott and Dunning, of Baltimore, Maryland, U.S.A. The preparation is put up in boxes containing 12 sealed tubes containing at choice 0·15, 0·2, 0·25, or 0·3 g. powder ready for solution—also in 5 g. ampoules for hospital use.

A Lecture
ON
BREAST-MILK FEEDING.[1]

BY CATHERINE CHISHOLM, M.D. MANCH.,
HON. PHYSICIAN FOR CHILDREN, NORTHERN HOSPITAL, MANCHESTER, AND HON. PHYSICIAN, MANCHESTER BABIES' HOSPITAL.

BREAST-MILK from its own mother is the only suitable food for the new-born child, and every child has a right to it. This fact emerges more and more clearly from the study of infant feeding and its results. Further, it may be a vital necessity for which no substitute can be found in the case of the premature child, or the victim of serious dyspepsia or any form of food intolerance. It is, therefore, to review our knowledge and to report the result of personal experience that this lecture is given, in the hope that it may afford some help to those who need it. That the information is needed is obvious, since those who have been practising among infants all their medical lives have had to seek out and learn so much.

Though all doctors and nurses continually advise breast-milk, there has been too little teaching and, indeed, too little study, into the best way of preserving the supply for the child and of ensuring its proper quality. For, as McCollum observes, the statement, so frequently reiterated, that breast-feeding of infants is superior to the best system of artificial feeding, needs to be qualified to some extent. There are, without question, in many parts of the world, large groups of people whose diets are such that the milk produced by the lactating mother is not a satisfactory food for the infant.

We are obviously concerned in managing breast-feeding with (1) mother and (2) child. As far as the mother is concerned, we may consider (*a*) character of the milk, (*b*) mechanism of secretion. In the child we consider (*a*) its power of suction, (*b*) its digestion and metabolism. As in other branches of medicine our practice must be based on physiological principles.

THE MOTHER.

The breast gland has been preparing for action during the whole life of the mother. Gaines[2] sums up the progressive stages in the development of the mammary gland as follows :—

"Embryonic Stage.—The first signs of mammary organs, the milk line, appear at an early stage in embryonic life, and growth is continued until the gland reaches a considerable development at birth.

Birth.—At birth a milky fluid may be expressed from the gland in either sex (the so-called witch's milk), indicating secretory activity, but this activity soon ceases and the gland remains quiescent until puberty.

Puberty.—At puberty, under the influence of the ovaries, growth is resumed and carried to a greater or less development, varying with the individual and the occurrence of pregnancy.

Pregnancy induces a great hypertrophy of the gland, and it reaches a high state of development, accompanied by the accumulation of colostrum.

Delivery.—By the time of delivery milk secretion proceeds actively, and if the milk is removed at short intervals by nursing or artificially secretion continues for a period of days, months, or years. The rate of secretion, however, after a time gradually decreases to zero. This decrease is favoured by a succeeding pregnancy.

Pregnancy.—Further growth of the gland ensues, but not as marked as in the preceding gestation.

Delivery.—At delivery milk secretion is again actively resumed. Whence the pregnancy cycle is repeated."

The following theories of the immediate process of lactation are held.

Lane-Claypon and Starling[3] think particular substance passes from fœtus to maternal circulation—stimulating and inhibiting the action of the gland in producing the milk during pregnancy.

(1) Increased blood in circulation after fœtus is gone provides material which is then secreted by the breast whose activity, like other glands, is increased by extra supply of blood; or (2) particular substances in blood favour secretion either (*a*) by purely stimulating the gland or (*b*) are of actual food value—i.e., that the food of the suckling is a direct continuation of the process of feeding the fœtus. (Pfaundler in Sommerfeld's Handbuch.)

SECRETION OF MILK.

Our knowledge of the complicated process of milk secretion may be summed up, according to Heinemann, as follows :—

"Epithelial cells take up material from the circulation and transform it into milk constituents, then discharge the altered substances into the lumina of the alveoli, and here the secretion is worked over into the finished product. The cells contribute from the chromatin and protoplasm part of their substance to the secretion and ultimately disappear. Part of the body fluid enters the gland ducts, which become distended and attract leukocytes, which, in turn, aid in the regeneration of cells partly by furnishing food and partly by removing degenerated cell substance. With the progress of lactation the leukocytic infiltration increases again, and at the end of lactation cell products are reabsorbed."

Gaines expresses the extent of our knowledge of the milk-flow in the following words :—

"During milking and nursing there is a reflex constriction of the gland; the removal of the milk from the gland is dependent upon the operation of this reflex; and the reflex is conditioned. The stimulation which naturally excites the reflex must be found in the friction and warmth of the sucking action of the young on the cutaneous sense-organs of the teat; with possibly a further source in the passive dilation of the sphincter muscle of the nipple by the passage of milk." Further: "Milking is a stronger excitant than an inserted canula; nursing is stronger than milking and direct action of pituitrin is stronger (*for the moment*) than nursing. Removal of milk from the gland is dependent upon this (nursing, &c.) reflex and it may be completely inhibited by anæsthesia. The psychic state of the mother modifies the strength of the reflex as shown by the flow of milk after absence of the young."

CHARACTER OF THE MILK.

The main constituents of normal breast-milk, as is generally known, are protein, lactose, and fat. Milk-sugar is only found in milk. If the milk gland is extirpated milk-sugar disappears from urine. Casein is a protein found nowhere in the body except in the mammary glands. There are two theories of its production: (1) enzyme action in gland, and (2) pairing of blood constituents and cellular material. The origin of lactalbumen is also obscure. From these proteins tryptophane, a split product of protein of especial value to growth, has been shown to be present in large proportions in both casein and lactalbumen, particularly in lactalbumen, the predominating protein in human milk (2·5 per cent. in casein, 4·0 per cent. in lactalbumen).

Milk-fat is not like body-fat. Heinemann says :—

It was formerly believed that milk-fat was the result of fatty degeneration of proteins, and that upon standing the quantity of milk-fat would increase at the expense of casein, but many observations have shown clearly that the composition of milk-fat is influenced by the fat in food. This fact has led to the belief that fat from food passes directly into the milk. However, this is not a necessary conclusion, because fat may be assimilated as body-fat and then reach the milk glands as such, or it may be broken down into building stones and then synthesised by the milk glands into milk-fat. In either case the resulting milk-fat would be dependent, in a measure at least, upon the original fat taken from the food and would have a similar composition. That such is the case is shown by comparison of the iodine number of body-fat, colostrum-fat—which is formed during a transition period—and genuine milk-fat.

The following table given by Engel, and taken from Sommerfeld's "Handbuch," illustrates the point.

It shows that while there is some difference between the iodine numbers of body-fat and colostrum, which might be expected, there is a much greater difference between body-fat and milk-fat. If the theory is correct that colostrum is a transition product between body fluids and milk, it would follow naturally that the fat of colostrum would also be a transition product. Extensive investigations by

[1] A post-graduate lecture delivered at the Manchester Babies Hospital.

[3] Proceedings of the Royal Society, 1906, lxxii., 505.

Engel (quoted from Pfaundler in Sommerfeld's "Handbuch") have led to the conclusion that milk-fat is not identical with body-fat, but that, since the iodine numbers of milk-fat and body-fat are approximately proportionate, there must be a dominating influence of body-fat upon milk-fat. Milk-fat, therefore, is dependent upon body-fat, but is not identical with it. Consequently, body-fat is either not the exclusive source of milk-fat, or the milk glands transform the body-fat into milk-fat. Colostrum-fat, however, is nearly identical with body-fat, while later fat formation is influenced also by the character of the food. The composition of milk-fat may fluctuate, therefore, according to which one of the two sources is predominant. However, the influence of the source of milk-fat is limited, since it is known that each species of mammal produces milk-fat of characteristic composition, so we must assume that there is a standard composition of fat derived from the milk of a certain species. This standard is variable only within narrow limits.

Engel's Table.

Mammal.	Iodine number of—		
	Body-fat.	Milk-fat.	Colostrum-fat.
Cow ..	42·0	32·0	46·1 to 50·5
Goat ..	44·1	37·0	46·9
Sheep ..	45·0	39·0	46·8
Human ..	61·5	43·0	62·0
Dog	72·7	58·3	—
Ass	78·2	72·0	—

The source of milk-fat has been investigated by Jordan and Jenter in a carefully controlled experiment. Recognising that many previous experiments did not cover a sufficiently long period of time, these authors fed a cow for 95 days on a ration from which the fat was nearly all extracted. The cow

"continued to secrete milk similar to that produced when fed on the same kind of hay and grain in their normal condition. The yield of milk-fat during the 95 days was 62·9 pounds. The food-fat eaten during this time was 11·6 pounds, only 5·7 pounds of which was digested. Consequently at least 57·2 pounds of milk-fat must have had some other source other than the food-fat. The milk-fat could not have come from previously stored body-fat, because, (1) the cow's body could have contained scarcely more than 60 pounds of fat at the beginning of the experiment; (2) she gained 47 pounds in body-weight during this period of time with no increase of body-nitrogen, and was judged to be a much fatter cow at the end; (3) the formation of this quantity of milk-fat from the body-fat would have caused a marked condition of emaciation which, because of an increase in body-weight, would have required the improbable increase in the body of 104 pounds of water and intestinal contents. During the 59 consecutive days 38·8 pounds of milk-fat were secreted and the urine nitrogen was equivalent to 33·3 pounds of protein. According to any accepted method of interpretation not over 17 pounds of fat could have been produced from this amount of metabolised protein. The quantity of milk solids secreted bore a definite relation neither to the digestible protein eaten nor to the extent of the protein metabolism. In view of these facts it is suggested that the well-known effect upon milk secretion of a narrow nutritive ratio is due in part to a stimulative, and not wholly to a constructive, function of the protein."

The authors also state that "the composition of the milk bore no definite relation to the amount and kind of food" and that "the changes in the proportion of milk solids was due almost wholly to changes in the percentage of fat."

The results of Jordan and Jenter's experiment appear to demonstrate that food-fats bear no necessary relation to formation of milk-fat. Protein metabolism can account only for part of the fat secreted in the milk, and some of the fat must have been derived from carbohydrates.

The assumption appears to be justified that milk-fat is derived from four sources—namely, food-fat, body-fat, protein, and carbohydrate. It is the function of the milk glands to transform these substances into milk-fat, and they produce a fat which varies but little from a standard suitable for the food of a certain species. It is true that the chemica composition of milk-fat in the same kind of milk varies within limits, according to the kind of fat contained in the food consumed. However, such variations are not permanent, and after a short period the normal constitution of the fat is restored, even when a particular fat is eaten with the food for a long time.

ACCESSORY FACTORS PRESENT IN MILK.

Immunising Bodies.—These are also present, particularly in the colostrum, which emphasises the importance of breast feeding even where it can only be carried on for two or three weeks. At birth the child has no capacity for providing its own resistance to the invasion of foreign substances.

Vitamins.—Ferments (lipose, lactose). Slight, if at all (Lane-Claypon).

A review in 1917[4] of the variations in chemical composition during the first 11 days shows that the order of variation in any group of individuals and also in any individual from day to day is fat, protein, lactose.

1. For each constituent there is a production plane and this plane is fixed for the individual, independent of nutrition and is dependent on the individual.
2. Little can be done to alter the proportions of the constituents by feeding.
3. An increase or decrease in lactose is accompanied by a change in the opposite direction in percentage of fat and protein.
4. Protein mechanism is best regulated and less dependent on factors controlling fat and lactose than they are on each other.

Drugs Appearing in Milk According to Holt.—These are: Saline cathartics, arsenic, salicylates, belladonna in full quantities, opium in poor milk may be dangerous, iodides, bromides, and mercury after prolonged use.

VARIABILITY OF MILK.

Variability of milk is seen in:—

1. Difference in composition due to breed.
2. Difference due to individuality—a superior individuality is one capable of using food in quantity above that required for maintenance and using its excess for milk production (Eccles and Reid).
3. Difference in same individual,[5] (*a*) at different milkings; (*b*) morning and evening milking—fat is richer in morning than at night; (*c*) fore, mid, and stripping; (*d*) according to length between meals—after long intervals percentage of all constituents is higher.
4. Difference in individuals during lactation. Quantity diminishes at the end of lactation but the solids increase. Fat is most variable, but protein rises considerably. In humans total nitrogen content falls. Fat declines for three months, then is constant four to five and rises at the end in cows. Sugar declines at the end. With regard to materials in diet of mother affecting milk, mothers in the fourth century were not allowed to take salt, acids bitter or sweet, or anything with a strong or fragrant odour. The substances giving flavour are said by Myers to be purely aromatic acids.[6] Certain drugs are known to affect the milk of the mother. With regard to vitamins, McCollum and Simmonds have shown that unless the nursing mother is receiving a diet rich in fat-soluble A-vitamin the growth of the young is unsatisfactory, though for a time her body has a reserve store. The mother is able, for a time, to produce water-soluble B-vitamin from her reserve supply, though it is not in the food. They showed that inorganic salts also were necessary in her diet though, again, for a time she is able to draw on her own reserves. They point out "that the human mother should have in her diet a liberal amount of milk . . . and of leaf vegetables." It is not enough that the diet shall furnish enough

[6] Myers: American Journal of Obstetrics.

aloric value and enough protein and shall afford ariety and palatability.

5. The influence of food is that when poorly-fed ows are placed on a well-balanced milk ration, roduction and quality are improved. But this hange cannot go beyond the limit which breed or ıdividuality is capable of producing.

$$\text{Nutritive ratio} = \frac{\text{carbohydrate} - 2\frac{1}{4}\text{ fat}}{\text{protein}}$$

6. Influence of weather is not of much importance. 'at and not fat solids are both down in summer. 'resh air and sunlight are of advantage.

7. Influence of exercise reduces milk and increases at. Nervous influences are important. Worry educes quantity, probably increases proteins, and ecreases fat.

8. Skill of milker.

The foregoing shows the difficulty of attempting o alter the character of the milk by dieting. The ollowing principles apparently guide the quality of he milk and the possibility of altering it for the hild.

(*a*) That the main factor is the inherited nursing apacity of the mother and her individual type of ilk which produces a certain ratio of fat, protein, nd carbohydrate.

(*b*) That, within limits, she draws on her own body issues for the sake of the child and even if underfed or a time produces a fair supply.

(*c*) The normal quantity is only increased by dministering to her a properly-balanced diet of ufficient quantity if she is underfed. If she is overfed nd under-exercised her health suffers and so does the uality of her milk.

(*d*) The later part of the feed is richest in fat and onsequently, for a time, the diet may be increased or mited in fat by totally exhausting the breasts or eding light on the two breasts rather than emptying ne fully.

(*e*) That as a longer interval between milking gives lower fat-content, the food can be varied in this way.

(*f*) That the administration of fats, such as linseed il, cod-liver oil, &c., for a time increases the fat-ontent of the milk, which, however, fairly soon ettles down to the mother's normal, and the continued alue of the administration of large quantities of ilk, of oatmeal, and of cod-liver oil is probably ı the vitamin and salt-content of the food (which IcCollum has shown is transmitted to the child nd which contains growth-producing powers) rather han in the improvement of the fat or protein onstituents.

(*g*) That the supply in quantity depends to a certain xtent on the demand. Budin shows this very clearly. f the breasts are well emptied the supply keeps up— the demand is lessened the quantity diminishes.

Thus, even if the character of the milk is investigated, ttle can be done to alter it by dieting a well-fed ıother. The examination of the milk is of most nportance in order to know what the baby is having nd to guide any supplemental feeding. As Hess, of hicago, says, "No baby should ever be deprived of s mother's milk only because of the results of a linical examination of the milk."

When examining milk we must note at what time f day it is taken, and see that a whole milking is aken, or that first and last portions are mixed, or hat the infant is allowed to nurse not more than wo minutes, and a sample is then taken.

Next we must consider the child's part in sucking efore going on to the practical application of these acts in the method we adopt for breast-feeding. The ucking apparatus consists, according to Feldman,[7] of he tongue, the hard and soft palates, the two cheeks, he uvula, the gums, and the lips. The pad, or so-called uction cushion, of fat is within the cheek and is the ze of an almond and remains even when the child is ery emaciated. Auerbach [8] believes that the cheeks are passive and that their indrawing is due to change of pressure inside the mouth. He thinks the nipple is grasped and compressed by the hermetically closed lips, the jaws, and the tongue, whilst the naso-pharynx is shut off behind the uvula. The depression of the lower jaw, with the consequent sinking of the floor of the mouth and tongue, increases the longitudinal diameter of the oral cavity and creates a diminished intra-oral pressure. In this way the milk is drawn into the mouth as the result of compression of the nipple as well as by the negative pressure. Basch found, by means of a special dynamometer, that the force of compression by the jaws is equal to 100–300 g. during the first few weeks of life and to 800 g. in children a few months old. He further determined, by means of a manometer, the suction energy of the child and the pressure under which the milk flows from the breast of the mother, and he came to the conclusion that without compression of the nipple by the lips and jaws the negative pressure alone is not sufficient to overcome the muscular tone of the nipple. Cramer disagrees with that opinion and believes that the aspiration force alone is quite capable of drawing the milk from the breast. The question is not altogether of academic interest. It has some practical importance, inasmuch as in the choice of a wet nurse it is desirable that the pressure required to draw off the milk from the woman's breast should correspond with the suction energy of the infant.

Cramer found that it took a baby five minutes to empty a bottle of 100 g. of milk under pressure of 5 cm., whilst a breast baby sucked 50 g. in 30 minutes under pressure of 50 cm.—i.e., the breast baby did 60 times the work of the bottle baby for half the result. Gundolme, quoted by Feldman (p. 451), found work of bottle baby : breast baby :: 1 : 11. This work of suction calls on (1) salivary secretion, (2) the use of muscles of jaw to help growth of bone.

Capacity of Stomach.—Pisci and Le Wald [9] showed the stomach emptied in three hours. The speed varied with quantity and quality of food. Willox [10] found in gastric radioscopy in children that (1) the shape of the stomach alters in digestion, and (2) the average time of emptying is 3¾ hours—the more fluid the food, the quicker being its passage through the stomach. Holt gives the capacity of stomach at birth as 1·2, at 2 weeks 1·5, and at 4 weeks 2·0. X ray examination shows that during a meal the milk spurts into the duodenum before the meal is finished, this being more commonly the case in naturally-fed babies than in artificially-fed babies.

Jefferson [11] has well shown how this takes place by describing the musculature forming a funnel for the direct passage of fluid on to the pyloric orifice. Observation on the amount of milk taken at a feeding by the normal breast-fed babies shows that the milk must pass directly on through the stomach, for the supply taken is greater than the capacity of the stomach. An infant of one month growing rapidly and on four-hourly feeds may take 6 oz. at a feed.

PRACTICAL APPLICATION.

Mothers feeding infants should have a full, well-balanced diet of the amount to which they are accustomed and containing milk and green vegetables. They should have plenty of fresh air and sufficiency of exercise which does not fatigue, an adequate amount of sleep, and no worry. The feeds should be given at regular intervals. The breasts should be prepared beforehand by painting the nipple with spirits and very gently drawing it out so that the erectile tissue may be developed. When the child is born it ought to be put regularly to the breast at fairly frequent intervals both to stimulate the milk and to involute the uterus, but the mother ought not to be unduly tired. For the first two days she may be full of aching pains. The intervals should be four-hourly the first day, then every 2½ hours till the milk is

[11] Journal of Anatomy and Physiology, 1915, 165.

coming well. As soon as possible the child may then be put on three-hourly feeds, and if strong, on four-hourly feeds. If the milk does not come the child should be given a little sugar-water after it has exercised itself on the breast, but it must not be given the sugar-water first as it needs a hungry child to pull well. The child, however, must not be left hungry long or it loses patience with the breast and also begins to lose energy itself. A child does not bear long starvation, especially if it is very tiny.

The child should be wakened to be fed at the proper time. As a rule, one breast only should be given, but under the following circumstances both may be given: (1) during the first few days to stimulate secretion; (2) to weak babies; (3) to overfed babies, so that they do not empty the breast, and get a meal light in fat; (4) where the milk is failing, so that the full stimulus may be exerted and because it needs both breasts. In this case the first must be thoroughly emptied and the second used first at the next meal. Dr. Lucy Naish describes the aversion or predilection of the child to one breast, which partly accounts for some children getting more at one than another meal. She also points out the proper position of the child when nursing—namely, lying across the mother who has a pillow under the arm supporting the child. This gives a slightly raised position to the chest and head of the child. This, in my opinion, is an important point where there is any tendency to vomit, as it allows the air bubble in the stomach an opportunity of escape. The child should not be allowed to take the food too quickly, and an opportunity for allowing air from the stomach to escape should be given by raising the child once or twice during the meal. If the child is very weak and cannot pull on the breast the milk must be drawn off and the baby fed with a bottle or Breck feeder rather than a spoon in order that his muscular powers of suction may increase. If he is too weak, of course, a spoon or pipette is necessary. If the nipples are very poor, again milk must be drawn off by a pump or a nipple-shield used till the nipple improves. As the child is fed and grows stronger it will be able to pull on the breast. The attempt to breast-feed ought not to be given up readily. I have known it take a month to really establish breast-feeding, which has then gone for five months without trouble.

Fats.—Lactagol will for a time enrich the milk and may for longer encourage the flow but the primary enrichment soon goes. Massage, hot douches, and sinusoidal electricity can also be of value to assist in keeping the supply of milk. The technique of electrical treatment is as follows: Gentle massage for ten minutes with the hands oiled and well soaped in hot soapy water, only using a kneading movement, avoiding the nipples. Remove traces of soap, &c., with warm water, dry the breasts, and apply faradism. Use fairly large lint pads soaked in warm water—having cut out centre of pad to avoid touching nipples. Use a piece of metal gauze as electrode, also with centre cut out; fix with bandage. Give just enough current for patient to feel a pricking sensation. Give on alternate days, beginning with 10 and increasing to 20 minutes.

As to quantity—"Let the child on the breast drink according to its appetite" says Variot—and this is wise within limits. If the child is progressing satisfactorily it is sound advice. The child will take very different amounts at different hours in the same day, six ounces at one feeding and two ounces at another. The breast-fed child is, on the whole, more likely to suffer from under-feeding than over-feeding. On the other hand, some children do appear to demand too much food, with consequent sickness.

As to time, the child gets all the milk it is going to get in the first few minutes. It is useless to leave it for a long time in order to get more. It is, of course, necessary for it to empty the breast in order that the supply may be preserved, so it does not do to hurry the child too much. Smith and Merritt [12] conclude that a normal baby who gets milk from one breast needs to be nursed only from six to eight minutes, rarely from 10 to 12 minutes.

A baby on both breasts may be nursed from six to eight minutes on the first, and from five to seven on the second. Actual weighing times observed by myself on a month old baby weighing under 9 lb. were: 2 oz. in first 2 minutes; 1¾ oz. in second 2 minutes; ¾ oz. in third 2½ minutes; none in fourth 2 minutes. Other breast: 1¾ oz. in first 2 minutes; ¾ oz. in second 2 minutes. Total 7 oz. in 12 minutes.

It is interesting to note the slower rate for second breast due, presumably, to lessened desire for food. When breast-milk is failing try supplementary feeds after the mother's feeding in order to keep up stimulation by emptying the breasts. In the case of difficulty with an infant who will not take the bottle after the breast at first, he must be taught the use of the bottle if necessary when hungry, the milk of the mother being thoroughly expressed later, if necessary, by the hands or the pump.

FOSTER-MOTHERS.

That breast-milk from a foster-mother is the next best feed to mother's milk goes without saying. So in a hospital such as this Babies' Hospital the presence of nursing mothers is invaluable for the most sick infants. In the choice of a mother appearances are very deceptive. The most promising looking nurses in our experience have not proved to be the best. Observation of her supply is the only means of forming a judgment. Our best mother was a poor-looking specimen who has grown young-looking and well in hospital, and proved a very satisfactory foster-mother. Her baby is now 12 months old and she is still regularly giving us 31 oz. per day. It is, of course, essential that the mother should be carefully examined and her history and character known. We have, in this hospital, largely followed what seemed to me the exceedingly practical methods of Dr. Fritz Talbot, of Boston. Mothers are chosen carefully and examined by ordinary clinical methods, and blood tests are taken.

The mother brings her baby with her for three reasons: (1) it has first claim on its mother's milk (in New York the foster-mothers' children deprived of their mother's milk had a high mortality) and the child taken with the mother gets some mother's milk, mother's care, and supervision; (2) it keeps the mother happy and content, for she sees her baby does not suffer from her service to others, and she is earning her bread and still doing her duty to her own child; (3) the good condition of her child is some criterion of the value of her own milk.

The child has three feeds from its mother each day. The rest of the milk goes to the hospital. The mother does not, as a rule, suckle the foster children, lest by any chance any of our infants prove to be syphilitic. As has been shown, it is better, both for mother and child, where there is only one nursling and where mother and child are both healthy, that the mother should feed it naturally and directly on the breast. But in a hospital such as this the milk is very precious. We have found, time after time, that the substitution of one or two breast meals a day may make a difference in the progress of a very dyspeptic case where more milk cannot be spared. Experience shows that the psychological effect on English women of nursing several babies is to produce dislike, nausea, and a suppression of the milk. We therefore arrange for the milk to be drawn off. The whole arrangements for these women are in the hands of the sister who superintends the preparation of the feeds. She teaches the women to draw off the milk. They each have a tray with all the necessary implements which are kept scrupulously clean. They are taught to clean their hands. Special nursing overalls are supplied to them and their hygienic arrangements supervised. Their milk is tested from time to time. Their own health is carefully watched. Our mothers have been healthy and well the whole of the time.

[12] Arch. Pediat., N.Y., 1922, xxxix., 371–373.

We have had five mothers in the hospital since March 1st last year. At first the mothers were paid £1 a week, now they are paid 10*s.* a week. Each mother does domestic work in the hospital to the value, according to the matron's estimate, of 10*s.* a week. Each mother supplies from 27 to 31 oz. of milk per day besides the milk for her own child. According to Budin, the milk varies with the number of nurslings. Our mothers have been fairly constant in their supply, but that is because the number of nurslings has not varied. The full amount of milk available has been drawn off and distributed as required.

METHOD OF FEEDING.

It must be remembered that a much less quantity of breast-milk may be sufficient for a child's feed than if a cow's milk dilution feed were used. A premature child may need only eight ounces of breast-milk per day. A very delicate child may not be able to digest full human milk. Budin found this out and used to give pepsin powder to some of his infants before the meal. We have not done this, but we have frequently had occasion to dilute the milk, and have found that food tolerance can be over-balanced by a too high feed of breast-milk just as seriously as when giving a cow's milk feed. When the child is taking from the breast directly the feed can be limited and water given just before the feed or Budin's plan of the pepsin powders may be attempted. Before weaning is resorted to in cases where the breast-milk is said not to suit the digestion of the child and these methods have failed, the milk can be drawn off and diluted. Where dilution has taken place, and where it is obvious that more sugar can be tolerated, sugar of milk may be added in the proper proportions. Occasionally the feed has to be given by the spoon, pipette, or Breck feeder, and in some cases it is well to "gavage" some of the feeds each day to save expenditure of energy in a very delicate child. Gavaging is easy in the premature infant.

A Lecture
ON
TESTS FOR CURE OF GONORRHŒA IN WOMEN.

Delivered at the London Lock Hospital on Feb. 22nd, 1924,

BY J. JOHNSTON ABRAHAM, C.B.E., D.S.O., M.D. DUB., F.R.C.S. ENG.,
SURGEON, LONDON LOCK HOSPITALS; SENIOR SURGEON, KENSINGTON GENERAL HOSPITAL, ETC.

I AM constantly being asked by the patient, or her doctor, or someone interested in the work, how one knows when a woman is cured of gonorrhœa; and I have to confess that it is often a most difficult question to decide, because the two most sensitive testing media we know of are debarred us experimentally, although they are essential to an absolutely definite reply. These two media are the mucous membrane of the male urethra and the conjunctiva of the child. They will detect the gonococcus when every other test fails; and it is unfortunate, from our standpoint, that the reliability of all the other tests we apply are finally judged mainly on the reactions of these two media, for, when the question of cure arises in a young woman, we are really being asked: (1) If the woman resumes connexion will she, or will she not, infect a partner previously free from the disease? (2) If she becomes pregnant, is the child at birth exposed to the risk of gonococcal conjunctivitis?

In women past the child-bearing age only the first question matters; and even that is often of minor importance, for what usually then concerns her is that she should be assured that she will not suffer from any of the chronic sequelæ, urinary, genital, or metastatic, which are the consequences of inadequate or unsuccessful treatment.

CERTAINTY OF CURE WITH PROPER TREATMENT.

What are we to say to a woman in either of these categories, and what tests can we apply to help us to a definite decision? The belief, probably first enunciated by Noeggereth, that when a woman becomes infected with the gonococcus she never gets rid of it, has been accepted and supported by many gynæcologists since his time; but it is quite untrue. Women, properly treated, can recover completely from gonorrhœa without a trace of after-effect. The gynæcologist sees the failures, not the successes, and judges accordingly. His mental state is similar to that of the neurologist, who, seeing case after case of tabes or general paresis, and influenced by the continual drip suggestion, comes to the conclusion that syphilis is incurable.

Another factor that has helped to make the belief in the incurability of the disease in woman so prevalent is that, whilst men have had skilled treatment for gonorrhœa for many years, the treatment of women for this complaint has been largely in the hands of physicians who have had no special training in the work. Their methods of attacking the disease have, in consequence, been perfunctory in the extreme, and their standards of cure totally inadequate. In addition, there is the ever-present shadow of the prostitute, always stopping treatment as soon as obvious symptoms disappear, and invariably becoming reinfected, if by any chance she has ever been cured. Following her, in a lesser degree, is the average out-patient, continuing her ordinary sexual life all the time she is undergoing treatment, probably with the husband who gave her the disease, and who himself has never been cured. To those who have to handle patients of this description, pessimism is natural; it could hardly be otherwise. And most of the literature dealing with the subject, especially on the continent, is derived from this source.

In private practice, however, and in an institution like the Lock Hospital, where a patient can be segregated for months, things are vastly different. Given proper treatment a cure can be effected in average cases in some three to six months. In acute cases, seen from the start, one can often effect a cure in two months. Such results conduce to a reasonable optimism.

One of the pitfalls of practice is the habit of treating patients as if they lived self-contained lives. They do not. It is useless promising a wife permanent cure unless one is certain her husband is free from the disease. No stringency of test can overcome this difficulty, and recurrence after passing successfully all known tests is not necessarily due to failure of the tests. Nothing, obviously, can be promised if there is any sign of disease in the husband. These points, self-evident when pointed out, are not always remembered; and when a case will not clear up, or recurs after apparent cure, one should insist on examining the husband, if this has not already been done.

Remembering all these precautions, one may now proceed with a chastened optimism to consider what is an adequate standard of cure, one which will be sufficient for general use, and not too elaborate to defeat its own ends by setting up an ideal impossible to attain. Such tests will obviously depend upon: (1) clinical signs; (2) bacteriological results; and (3) possibly serological findings.

CLINICAL SIGNS.

The first criterion, then, is that all clinical signs of the disease must have disappeared. By this is meant: (1) That there is now no induration of Bartholin's glands, or sign of inflammation around their orifices; (2) that the urethra, similarly, appears normal on inspection externally, palpation through the vagina, and urethroscopic examination; (3) that the para-urethral crypts, especially Skene's tubules, show no inflammatory signs; (4) that the vaginal introitus is

normal in colour, with no inflamed tags or crypts around it, and that pain is not complained of when a speculum is passed; (5) that the cervix appears normal, the secretion clear, and no erosion is present; (6) that the uterus and tubes, on bimanual examination, are apparently free from disease; and (7) that the anal orifice seems normal, and there are no signs of inflammation or discharge in the anal canal on passing a speculum.

BACTERIOLOGICAL SIGNS.

The second essential desideratum is that all bacteriological signs of disease should be absent. Evidence on this point can only be accepted if the following technique, and the precautions mentioned below, are observed when making the examination:—

(1) Smears, taken from the urethra by means of a sterile platinum loop inserted half an inch down, should be negative for pus cells and gonococci in a patient who has had a provocative injection of 1 c.cm. gonococcal proteose 24 hours previously. The urethra should have been massaged gently forward before the loop is inserted, and the surgeon should have assured himself that the patient has not passed urine for some hours before examination. (2) The urine, held for some hours before examination, should be clear, acid, free from albumin, and contain no gonococci, or pus, when the centrifugalised deposit is examined under the microscope. (3) Smears taken from the orifices of Bartholin's glands and from Skene's tubules should be negative. (4) Smears taken from the cervix by means of a platinum loop should be negative, for gonococci and pus, when taken before menstruation, just after menstruation has ceased, and 24 hours after a provocative injection of 1 c.cm. gonococcal proteose. (5) Smears taken from the anal canal should be negative for the gonococcus. The anus is a fruitful source of reinfection. Gonococci can often be found there when they are absent elsewhere in women. Surgeons dealing with men only frequently forget this. Gonococcal infection of the anus and rectum in men is rarely seen, except at a hospital dealing with diseases of the rectum. I saw three cases in one year at the Gordon Hospital. It is very uncommon at the Lock Hospital in men. I have seen only one case there in the last five years. This, of course, is due to the fact that anal gonorrhœa in men is generally due to unnatural practices. In women, however, the cause is quite different; the disease is gravitational and, if looked for, it is surprising how often one finds it. When vulvitis is present, or when there is a history of recent vulvitis, it is the rule rather than the exception to find gonococci in the anal smear.

I have always been averse to the use of irritating applications of silver nitrate to the urethra at any time, especially when they are done to provoke discharge in the hopes of thereby finding the gonococcus. The method seems to me to savour of barbarism, and to be clinically unsound. Since the discovery of the value of a provocative injection of gonococcal proteose, or "residual" vaccine, it appears to be quite unjustifiable. In the cervix, however, the same objection cannot be maintained; and, if in doubt, or if a provocative dose of vaccine, or proteose, is not available or convenient, it may be used. It will be noted that I have said nothing about attempting to grow the gonococcus from smears in women. That is because I have been painfully impressed with the uselessness of the method. Time and again, in my experience, cultures have been negative for the gonococcus when smears have been positive, because organisms such as staphylococci grow so rapidly as to smother any gonococcal colonies which may be present. Anyone who trusts, therefore, in a negative cultural report alone, in a woman patient, is living in a fool's paradise. There is, of course, no objection to having cultures made in addition to smear examination, and in private practice it may often be advisable, as a positive report, when present, strengthens one's position. But in a large clinic, where thousands of examinations have to be made yearly, where all the facilities are available, where skill in growing the organism is at its maximum, the proportion of successful cultures is so small in women that to my mind it is a waste of a skilled pathologist's time to order them. I therefore never use cultural methods in women, except when examining for cystitis, pyelitis, or systemic infection. In men, however, cultural methods have much greater chances of success, and none of the above remarks refer to them.

SEROLOGICAL TEST.

To the clinician, anxious not to make a mistake that may have disastrously far-reaching effects, the theory of the complement-fixation test (C.F.T.) is intensely attractive, especially when his patient is a woman; for many of these patients are brought for examination having no idea what is suspected to be the matter with them—the word gonorrhœa is never mentioned. If such a simple procedure, therefore, were possible as taking a specimen of blood from the arm, sending it to a pathologist, and on his report being able to say definitely this is, or is not, a case of gonorrhœa, or this case is now clear of gonorrhœa, the surgeon concerned would be only too thankful to adopt it. Gone would be the careful and exhaustive physical examination, the instrumentation, the taking of smears from half a dozen places, at intervals spread over half a dozen months, the cautious prognosis, even then, if everything appears satisfactory. Gone would be all the worry and anxiety, both for the patient and her medical attendant. But, alas, it is not possible. The golden road to an easy prognosis is not yet. A patient may have a profuse gonococcal discharge, and yet give a negative C.F.T. for the first two or three months of the attack. On the other hand, a case may have cleared up completely, and yet the patient may give a positive C.F.T. when all infection is over. Even the advocates of the method admit this, as antibodies do not develop sufficiently rapidly in the early days of the disease to influence the reaction, and they persist for months after active disease has ceased, and so give a positive result. Theoretically, the test should become negative three months after infection has ceased. But does it? From observations I have made I very much doubt it. It seems quite unreliable if a patient has ever had a course of vaccines—a very great drawback in these days, when nearly every patient has had at least one course of vaccines at some stage of her disease. It may still be positive when a patient has resumed normal married life, had no signs of metastatic trouble, and given birth to a perfectly healthy child to a second husband who is himself free from the disease—a combination of circumstances not infrequent, on account of the re-marriage of war widows. I have known it positive four years after all symptoms had disappeared. That might mean, of course, that there was a hidden focus keeping up the supply of antibodies. If so, it was so hidden that for ordinary marital life it could be neglected; and in this particular case I asked myself the question: Was it fair to debar the patient from marriage simply on a positive C.F.T. with no other symptoms? I came to the conclusion it was not. Results have justified that conclusion.

VALUE OF THE COMPLEMENT-FIXATION TEST.

Personally, I was greatly attracted by the test at first, and commenced using it with a distinct bias in its favour. For over a year I tried it on every woman who came up to the out-patient department of the Lock Hospital, either for treatment or for a test of cure; and at the end of that time, on considering my results, I felt compelled to abandon it as a routine. Three conclusions, I think I may safely say, I was able to deduce from my experience:—

1. That, in the acute stage of a urogenital infection, the C.F.T. was useless as a means of differentiating between a gonococcal and a non-gonococcal infection. This, of course, only confirmed what was already known.

2. That, if a urogenital infection had existed from two to six months, then a negative C.F.T. indicated that the disease was non-gonococcal, and this would be confirmed by the bacteriological tests—in other words, the reaction is specific. This also agrees with previous findings.

3. That if a positive C.F.T. is present a year after all clinical and bacteriological symptoms have disappeared, it may be neglected for practical purposes. There may, of course, be some hidden focus tucked away somewhere which will perhaps produce a gonococcal iritis years later, but it is impracticable to debar a patient from marriage on that account. All clinical observers will, I think, agree with me here.

The truth, then, is that in the early stages of gonorrhœa the test is not sufficiently powerful to diagnose the disease, in the middle stages it will differentiate between gonococcal and non-gonococcal disease, and in the convalescent stage it is too delicate for use as a practical sign of cure.

SUMMARY.

I would say then, that, with the present technique, the complement-fixation test, as an indication of cure, if positive when all the other tests are negative, may be neglected, and one should rely for practical purposes on the two previous sets of tests, clinical and bacteriological. If these tests are negative, the patient should be asked to return in two months, and the tests repeated. If again satisfactory, the same procedure should be repeated in four months. If, at the end of six months without treatment, the patient still shows no sign of return, clinical or bacteriological, I think we may safely assume she is cured. A year later, if a repetition of the tests is negative, she can safely resume marital life.

That is the standard of cure at which I aim. It is not too high or too difficult to attain. It leaves, of course, a little element of uncertainty; but anything more, to my mind, would be an impossible ideal. If fresh manifestations show themselves after such a series of tests, either the method of testing is at fault or the patient has acquired a fresh infection. Before assuming the tests were inadequate one should remember that a moral twist cannot be cured by surgical means. A lot of the pessimism about the curability of gonorrhœa in woman is due to a failure to recognise this fact.

AUTO-HÆMO-THERAPY IN BACTERIAL INFECTIONS.[1]

BY S. G. BILLINGTON, M.B., B.S. LOND., F.R.C.S. EDIN.,

PATHOLOGIST, BACTERIOLOGIST, HON. ASSISTANT PHYSICIAN, WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL; CONSULTING BACTERIOLOGIST, WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.

SOME six years ago I began an investigation into the therapeutic possibilities of the blood as a result of two phenomena observed in France during the war, and the following are preliminary notes upon it.

1. In the autumn of 1916, at a Base Hospital to which I was bacteriologist, a small epidemic of lobar pneumonia occurred. A pure culture of a pneumococcus was obtained from the blood in one of these cases, and a sensitised vaccine made by Besredka's method with anti-pneumococcal serum. The extraordinary response in every case of this small series of 10 or 12 convinced me that a specific remedy for pneumonia existed, and to obtain it two problems had to be solved: (*a*) The causal organism must be obtained quickly and with certainty, and (*b*) a rapid method of making an artificially sensitised vaccine must be found.

2. Hundreds of bacteriologists had been investigating the blood in trench fever. The results in all cases were negative, and no virus was grown or demonstrated in films. From this mass of negative work, however, two facts emerged: It was proved (*a*) that the blood transmitted the disease, and that the whole blood and various parts of the blood contained the causal virus; and (*b*) that the disease could be transmitted by the excreta of the body louse.

In view of these two established facts with regard to trench fever, one was forced to come to the conclusion that the blood contained the causal virus, and not only contained it, but must contain it in large numbers if the body louse could extract sufficient to transmit the disease. In the present communication I shall describe how coccoid-like structures can be produced from the blood in from 10 to 60 minutes, and how these emulsions can be utilised in the treatment and diagnosis of bacterial infections. The unit of blood taken is one drop from a fine hypodermic needle. The blood is collected with aseptic precautions from any convenient vein, usually in front of the elbow, an all-glass hypodermic syringe being used.

During the last few years the coccoid structures described have been produced from whole blood and washed cells in a variety of ways; but the following three media have been selected as the most suitable for routine work:—

1. Doubly distilled water containing 0·5 per cent. ammonium carbonate.
2. Peptone (Witte's or Fairchild's), 2 per cent.; sodium chloride, 0·5 per cent.; ammonium citrate, 0·05 per cent.; calcium citrate, 0·02 per cent.; distilled water.
3. Peptone, 2 per cent.; Lemco, 0·5 per cent.; ammonium citrate, 0·05 per cent.; tap water.

In preparing Nos. 2 and 3 the citrates are not added until the other constituents have been dissolved and steamed, and if the reaction of the peptone or broth is acid it should be made just neutral to litmus. Witte's peptone usually gives a neutral reaction, but Fairchild's is generally acid. The media are neutral citrated solutions, and are finally sterilised by steaming for half an hour on three consecutive days. The ammonium carbonate distilled water is sterilised by steaming for 10 to 15 minutes on three consecutive days, and should not be kept for more than two or three weeks as the salt appears to slowly dissociate. Medium 1 produces immediate and complete hæmolysis; 2 and 3 contain just sufficient salt to prevent hæmolysis. The quantity of medium taken per tube is about 3 to 6 c.cm., and one drop of blood from a hypodermic needle introduced. The tubes are then rotated gently to diffuse the blood in the medium and placed in a water-bath at 58°–60° C. In from 10 to 20 minutes the contents of the tubes become turbid, and a few minutes later milky. Films made of the emulsions show innumerable coccoid bodies of varying size, many arranged in pairs or short chains of four. In the citrated media these bodies are less discrete, and masses of them can usually be found at the edges of the film. Red cells in all stages of disintegration are also seen. These coccoid bodies do not stain readily with the basic dyes unless an acid mordant is first used, 5 per cent. tannic acid being the best. They are generally Gram-negative. They take up the pink with the Romanowski stains direct, but the blue after free use of tannic acid. Before describing the manipulation of the emulsions of these coccoid bodies to convert them into therapeutic agents, I must briefly describe the technique that I have used for making vaccines during the last four years.

Technique Used in Making Agglutinated Vaccine.

The emulsion of the organism is made in ordinary neutral bouillon, and may be made from either solid or liquid media; it is diluted down to one of about 2000 million organisms per c.cm., and is heated for about 10 minutes in a water-bath at 60° C. The essential point of this stage is to get the organisms as discrete as possible, and this is by no means easy with some of the streptococci and other organisms prevalent at the present time. About 4 c.cm. of this emulsion are then transferred to each of a number of large tubes containing about 25 c.cm. of sterile normal

[1] A paper read before the Midland Medical Society on Feb. 27th, 1924.

saline. The diluted emulsion is then heated for 10 minutes in the water-bath at 60° C., about two-thirds only of the emulsion being submerged in order to obtain effective mixing convection currents. One drop of 2 per cent. NaOH is then added to each tube, and the heating at 60° C. continued for another 10 minutes. Four or five drops of 2 per cent. NaOH are added to each tube, the Bunsen heating the water-bath removed, and each tube rotated to hasten the mixing of the caustic soda. Two drops of liquor ammoniæ fort. are added to each tube, which is rotated and replaced in the cooling bath. The diluted emulsion in the saline becomes slightly milky on the addition of the caustic soda, this increases on the addition of the ammonia, and in a few minutes the tube contents resemble in appearance a positive macroscopic agglutination. A white flocculent precipitate settles to the bottom of the tubes as the water-bath cools. The deposits are washed twice in sterile normal saline in a water-bath at 55°–60° C., and finally in 0·5 per cent. carbolic saline, from which the vaccine is diluted to the required strength and bottled in carbolic saline. A film made of this deposit shows the bacteria agglutinated to varying extents and lying in a homogeneous material. The bacteria are black or red according to their Gram reactions, and the matrix is stained light red.

Standardisation of Dose.

The number of organisms per c.cm. is estimated before the agglutinating process is applied, and 12 c.cm. of an emulsion containing 2000 million per c.cm. will give a total of 24,000 million in the final product. I aim at a standard strength in the vaccine of about 1000 million per c.cm., but if the technique is right a variation of a few hundred millions is immaterial. In my experience the correct dosage for any individual patient must be found by commencing on the small side and increasing the dose until a satisfactory response results. The dosage in the case of vaccines is even more elastic than in the case of drugs where a wide range is universally recognised. It is not within the scope of the present note to enter into details as to what may or may not happen during the preparation of an agglutinated vaccine as described; but if I give briefly a hypothetical explanation it may be easier for any bacteriologist who wishes to make vaccines by this method to do so. The bacteria should be regarded as being surrounded by a homogeneous material that we may call the bacterial matrix. This matrix consists of an outer toxic portion, which is a nitrogen containing fat or lipoid, and an inner portion which is protein.

The objects aimed at in the preparation of the vaccines are threefold: (1) The production of a discrete emulsion, so that each individual organism is completely exposed to constituents dissolved in the emulsifying fluid. (2) The removal of the lipoid by weak caustic soda which is a fat solvent and forms a soap. The temperature varies from 56°–64° C. for different organisms. (3) The precipitation of the protein element of the matrix by the addition of more soda and then ammonia. Before precipitation the bacterial protein should have become saturated with lime, taken up from the broth and saline constituting the diluting medium. The supernatant fluid is a toxic soapy solution, and the precipitate consists of clumped bacteria lying in a lime-protein structureless matrix. I do not put forward this explanation with any claim that it is what actually happens, but merely as an intelligent objective, and if the technique is carried out according to it the desired end-product will be obtained. The two most important factors are the production of a discrete emulsion and the using of a broth and saline with a suitable lime content. If the emulsion contains clumps of organisms, these will appear in the vaccine with toxic centres, which have neither had the lipoid removed nor the protein saturated with lime. The lime-content of the saline I shall deal with later.

In watching the clinical results following the use of vaccines which are supposed to produce no reactions three very definite facts can be observed: Such vaccines (1) may produce all the beneficial results without any of the preliminary unpleasant or dangerous disturbances or reactions; (2) may be apparently inert as regards any good or bad effects produced; and (3) may produce severe reactions. If the lipoid is imperfectly removed, the vaccine may produce a reaction, and owing to the larger doses given the reaction may be severe. Such a faulty vaccine also frequently leaves small hard nodules at the site of injection, the organisms not being absorbed readily, with consequent diminution in the evidence of beneficial effects. If the protein matrix does not contain sufficient lime the therapeutic response is slight or nil. The results appear to depend upon the efficiency of the technique under the two headings of (*a*) lipoid removal, (*b*) lime saturation.

The term "agglutinated vaccines" is used because (1) they may not be detoxicated, and in the present state of our knowledge of bacterial toxins this is a term which conveys very little to me; (2) I am not prepared to put forward evidence that they are identical with sensitised vaccines, though clinically their effect is indistinguishable; (3) they are, however, agglutinated as regards the physical grouping or clumping of the bacteria.

Dosage.

The general scheme of dosage is that applied in the administration of sensitised vaccines. Three doses of say 500, 1000, and 1500 million may be given on three consecutive days with subsequent 1000 or 1500 million doses at three to seven days' interval. In my experience there is no object in exceeding a dose of about 2000 million, as if this dose does not produce a very definite response, it means that either the vaccine preparation technique has been faulty or the clinical diagnosis is wrong as regards the response of the disease to vaccine-therapy alone. This conclusion, of course, assumes that the vaccine contains the causal organism of the disease. The further manipulation of the emulsions of coccoid bodies obtained from blood is carried out on the principles just described. I do not put forward any claim that these structures are microbic, but shall use the term agglutinated "hæmo-vaccine" merely as a convenient term to indicate that therapeutically they exert some anti-bacterial effect. I shall confine the description of the manipulation of coccoid bodies from the ammonium carbonate distilled water, as the procedure in the citrated media is more complicated and less easy to bring to a satisfctory end-point.

One drop of blood is allowed to fall into about 6 c.cm. of ammonium carbonate distilled water. A zone of hæmolysis will be seen extending about half way up the tube from the bulk of the drop of blood at the bottom of the tube. With a sterile pipette the upper 5½ c.cm. of the tube contents are removed to a large sterile tube. The emulsion thus obtained has a faint pink colour, and a portion of the drop of blood is left at the bottom of the original tube. I cannot enter into the reasons for this procedure here, but I have cause to believe that the upper portion of the hæmolysed zone is more effective than the whole blood The diluted blood thus obtained is placed in a water-bath at 58°–60° C. and left there till turbid, and films show coccoid bodies, as in Fig. 1. About 1 c.cm. of 0·02 per cent neutral citrated broth is then added and the tube replaced in the bath for two to three minutes. About 10 c.cm. of neutral broth are then added, and the emulsion again heated for a few minutes. To a series of large tubes of sterile normal saline 3–5 c.cm. of the coccoid emulsion are then added and the process continued, as in the description of the preparation of agglutinated vaccines. The lime-content of the saline should be such that a considerable amorphous deposit is precipitated when 3–4 drops of 2 per cent. NaOH are added to about 15 c.cm. and the tube heated for 10 minutes at 60° C. If there is too much lime present the addition of a trace of caustic soda produces immediate turbidity and precipitation before the lipoid has been removed.

If there is too little lime the end-product is more or less inert. The dosage of the "hæmo-vaccine" of coccoid bodies is estimated by comparison with naked-eye turbidity of agglutinated vaccines, and diluted to a turbidity roughly corresponding to 1000 million organisms per c.cm. The administration is carried out on the principles adopted with sensitised vaccines.

Before proceeding to a description of the therapeutic effects, I would warn bacteriologists not to use these coccoid emulsions lightly. The technique is not easy to describe concisely; but very severe reactions may follow the use of imperfectly manipulated emulsions. The most dangerous elements are whole, or imperfectly disintegrated red cells, and emulsions containing these acquire an increased toxicity after standing in the cold for a few days. I have always investigated any new departure by animal experiment, and faulty emulsions, as described, have proved fatal to rabbits.

Investigations of the Coccoid Structures Described.

These fall under the two headings of scientific and clinical. Time, assistance, and equipment for scientific investigation have been meagre and limited. As a result I am unable to approach this aspect of the phenomenon as my findings are distinctly disjointed and incomplete. From the clinical side, however, I have had a unique opportunity of observing the effects of therapeutic administration. As physician in charge of a special department of clinical bacteriology in a large hospital, I am responsible for: (1) Supervision of isolation of the causal organism, (2) supervision of preparation of the vaccine, (3) supervision of administration of the vaccine, (4) determination of what additional forms of treatment are indicated, and (5) diagnosis of the condition for which the vaccine is administered.

Under these conditions many of the shortcomings of bacteriology in its clinical applications are avoided. In common with other forms of treatment, the entire structure of vaccine-therapy is built on a clinical basis. In the great majority of cases where a vaccine is administered and the patient improves, one wonders whether the improvement has occurred because of the vaccine or in spite of it, and the results are useless as regards the forming of any opinion as to the efficacy of the remedy. In a minority of cases, however, certain conclusions can reasonably be deduced, and where the total number is large, the minority represents hundreds of instances giving some information. The following four groups of conditions allow of certain deductions being made: (A) Acute fevers which run a moderately constant course, pneumonia being outstandingly the most constant of these; (B) diseases secondary to an unlocated infective focus: (C) toxæmias secondary to a known unremovable focus of infection; and (D) toxæmias secondary to obscure, unlocated, surgical foci.

Group A.—In pneumonia there is an inflammatory focus in the lung from which bacterial toxins are passed into the general circulation, and the vaccine should provide antibodies to neutralise the toxin. In the case of a sensitised vaccine clinical evidence of this neutralisation should occur in six to eight hours after the administration of the vaccine. The evidence takes the form of improvement in the patient's general condition with a fall of temperature, pulse, and to some extent respiration rate. The clinical evidence also points strongly to the neutralisation being a quantitative one, analogous to the neutralisation of diphtheria toxin by antitoxin. In this disease we recognise that a severe case will probably require a larger dose of antitoxin than a milder one, and the antitoxin is repeated until the toxæmia is controlled. In an ordinary case of pneumonia treated with average doses of sensitised vaccine the response is as in Chart 1. where a drop of about two degrees of temperature occurs six to eight hours after the administration of the vaccine. After keeping down for about 12 hours the temperature tends to rise again until a second dose of vaccine produces another fall.

Where the vaccine and toxin correspond in this way the fall of temperature and pulse in steps is very striking. If, on the other hand, the pneumonia is extensive, and the dose of vaccine not increased no very definite changes on the chart are noticed beyond perhaps a few transitory falls six to ten hours after the vaccine. The clinical point noticed, however, is that under the circumstances the patient's general condition seems to be very satisfactory. If the pneumonia is not extensive and one large dose of vaccine is given, the latter will often apparently completely and finally dispose of the toxæmia. When this is brought about on, say, the second day of the disease, it is very remarkable to see the patient apparently quite well and sitting up in bed with a normal temperature and pulse, but with a portion of the lung solid and all the physical signs of pneumonia present.

What deductions can be made from these results? We know that occasionally pneumonia aborts in the initial stage, but it is very rare to get two or three consecutive cases doing so. If the results described occur in six consecutive cases, it is sufficient evidence to warrant further investigation into the nature of the remedy apparently responsible. As my experience in the treatment of pneumonia extends from tens to hundreds, I find it still more difficult to come to any other conclusion than that these "auto-hæmo-vaccines," showing coccoid-like structures, exert some definite anti-bacterial effect. There is, however, another way of obtaining information, and this test I consistently apply where the patient is in hospital under my own observation. The temperature has been lowered on, say, the fourth day of the disease by one or two doses of vaccine to 100, and the patient's general condition is good. The vaccine is then stopped and the course watched. One of two things happens: either the temperature runs on in a modified form for four or five days, and then suddenly drops about the ninth day, or the temperature and pulse slowly creep up again, but are at once controlled by another dose of vaccine. It is very difficult to explain these attenuated courses by any factor outside the "vaccine."

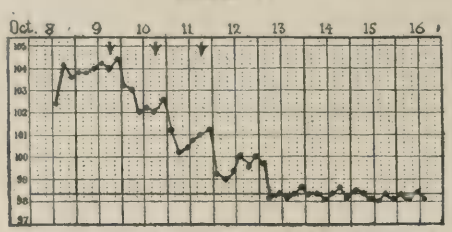
I do not claim for a moment that every case of pneumonia I have treated has responded as above described, but such a large percentage have done so that the principle appears to be sound. Where the response is not satisfactory also a reason can generally be found, and the chief causes of non-response are: (1) Faulty technique in preparation of the vaccine: As previously mentioned, I am quite sure that vaccines can be more or less inert though detoxicated if this term is to signify that they do not produce a reaction. A second vaccine made from the same emulsion, but with a different lime-saturating technique, may be just as effective as the first was inert. (2) Insufficient dosage: Three or four doses of, say, 500 million may have had no appreciable effect when a dose of 1500 million may at once control the disease. In these cases, however, it is difficult to estimate what the cumulative effect of the previous doses has been. (3) Faulty diagnosis: The entire mechanism of the above treatment of pneumonia rests upon a clinical basis, and the smallest empyema or metastatic abscess will completely negative results. The vaccine, however, is useful in diagnosis, and the exploration of an indefinite dull area because the patient failed to respond has yielded pus on several occasions, although the physical signs alone scarcely indicated pleural puncture.

When the pneumonia is associated with pleurisy, the response on the chart is usually less definite, and often occurs suddenly in three or four days. Finally, where the patient is moribund, and the myocardium and vaso-motor mechanism have already received a lethal dose of toxin, no neutralisation of the further supply will avert a fatal issue.

Group B.—In the second group of case I will give a typical example. A patient starts a course of "vaccine" for definite rheumatoid arthritis of two years' duration. The teeth appear sound, the arthritis has completely subsided in three months, and the "vaccine" is stopped. In six weeks there are

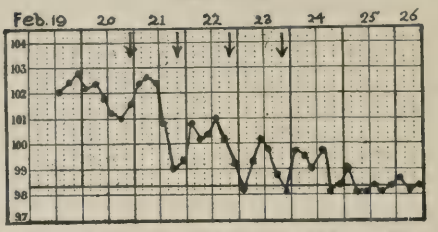
definite signs of relapse, the dental surgeon passes the teeth, and the arthritis again responds to the "vaccine," but again relapses in a few weeks. An X ray photograph then demonstrates the presence of an apical abscess. With the extraction of the tooth and a few doses of "vaccine" the arthritis disappears, and the patient is free from the disease two years later.

CHART 1.



Lobar pneumonia, October, 1916. Sensitised pneumococcal vaccine started on second day of disease. (Doses indicated by arrows.)

CHART 2.



Lobar pneumonia, February, 1923. Agglutinated "hæmo-vaccine" started on fourth day of disease.

Whatever the structures in the "hæmo-vaccine" may be, they would appear to exert a neutralising effect upon the toxins absorbed from the apical abscess.

Group C.—Chart 3 is that of a patient with severe phlegmasia alba dolens. The irregular septic temperature had been present for some weeks before starting the "hæmo-vaccine," which appears to definitely neutralise the absorption from the thrombosed vein for about 36 hours after each dose.

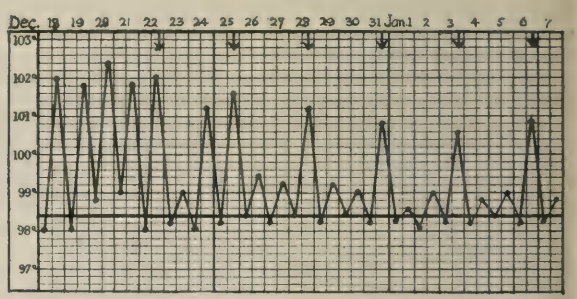
Group D.—In my experience of the use of "hæmo-vaccines" the most striking evidence of their antibacterial action has been in the lighting up of latent or obscure surgical foci. The action of a vaccine on an infective focus may take the form of a focal reaction or of a focal response. A focal reaction occurs where the vaccine used is one that produces a reaction and the disturbance is due to a temporary aggravation of the infective process. A focal response may follow the use of a sensitised vaccine, and is due to increased tension in a closed focus caused by antibacterial bodies entering the focus. If, for example, the corresponding sensitised vaccine is administered for a blind boil, one of two things will happen—either the boil will be absorbed and disappear, or it will rapidly come to a head and burst, and it is when the latter occurs in a closed space that signs and symptoms of response are evident. If the closed focus is situated in bone, or in a closed viscus such as the gall-bladder with obstruction in the duct, the addition of the serous exudate containing the antibodies results in increased tension, with consequent pain and evidence of increased toxæmia.

steps following the first three doses of vaccine, and the patient made an uninterrupted recovery. The intermediate condition between these two cases is where there is a focus present, but it is not under conditions where a slight increase in bulk will raise the tension. Examples are collections of pus such as an empyema and thrombosed veins in continuity with the blood-stream. In toxæmias secondary to this type of focus the vaccine has only a transitory beneficial effect or none at all. Although it exerts no localising effect, it indicates the presence of a focus which must be sought for on general clinical grounds.

The following two cases are examples of the localising effect:—

A boy had signs and symptoms of periostitis of the tibia, the periosteum was incised, and a small collection of pus exposed with apparently healthy subjacent bone. The temperature and pulse, however, remained up, and as there was a slight pleurisy present the origin of the toxæmia was obscure. In six to eight hours after the administration of a dose of "hæmo-vaccine" the boy developed excruciating pain in the tibia with a rise of temperature a few hours later.

CHART 3.

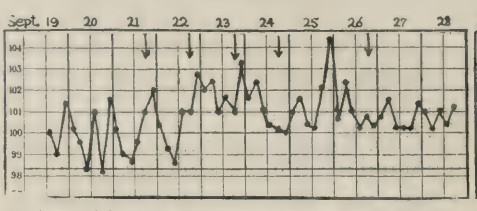


Puerperal white leg, December, 1919. "Auto-hæmo-vaccine" administered.

The bone was then opened and found to be infiltrated with pus.

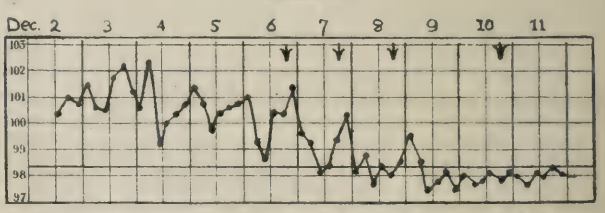
A woman, aged 29, for three weeks had been running an indefinite temperature with no localising signs or symptoms beyond a suspicion of jaundice at one time. A "vaccine" was administered with the object of possibly clearing up the infection, or more probably of localising the focus. On the

CHART 4.



Endocarditis with dental septic focus, September, 1922. "Auto-hæmo-vaccine" administered.

CHART 5.



Endocarditis without obvious focus, December, 1922. "Auto-hæmo-vaccine" administered.

The two Charts 4 and 5 are those of two cases of endocarditis. In Chart 4 there was an obviously septic tooth present. After the administration of the vaccine there was severe pain in the tooth, the swelling of the gum increased, the temperature rose and became continuous instead of intermittent, and the patient, who refused to have the tooth extracted, died. In Chart 5, clinically an identical case but with no obvious focus of infection, the temperature descended in three fourth day, after three doses, the patient had a rigor accompanied by severe pain and tenderness in the region of the gall-bladder. An immediate operation was performed, and the gall-bladder was found to be distended with sero-purulent fluid.

I could enumerate 30 or 40 examples of obscure surgical foci localised in this way. Whatever these "hæmo-vaccines" may contain from a scientific point of view, they are extremely useful in practical clinical

diagnosis, and can be prepared in less than two hours, if necessary in a portable apparatus at the patient's house. I have endeavoured to keep a very open mind on the clinical results, but in the four groups of cases described it is difficult to come to any conclusion other than that the agglutinated emulsions of these small coccoid-like structures exert an antibacterial effect.

Having described the methods of producing the coccoid bodies, their further manipulations, and the results of their administration in the form of agglutinated emulsions, one naturally asks the questions: (1) Where do they come from? (2) What are they? (3) How do they exert their bactericidal powers? These questions open up very difficult scientific problems, to which I am not prepared to reply. From the indefinite and incomplete investigations that I have made in that direction, I have come to the conclusion that in a small laboratory, staffed and equipped for routine work, it would take a life-time to answer the above questions with the requisite scientific evidence. They appear to originate from the red blood cells. So far as their morphological appearance goes, they might be fragments of red cell stroma, colloidal particles of protein, some kind of micro-organism, or some particles which at present are not recognised as definite entities. Their exact mode of action is equally obscure. They may act in a manner analogous to peptone or shock protein-therapy. On the other hand, they act without producing any shock or reaction, and the fact that these coccoid bodies can be produced in vitro in peptone or other proteins would rather suggest that therapeutic proteins act by producing some form of coccoid body in vivo. I have a certain amount of evidence that the structures exert their bactericidal power by acting as calcium vehicles; but beyond that I am not prepared to put forward suggestions.

Although I can claim so little from the scientific side, I have not the slightest doubt as to the clinical evidences of antibacterial action. The conditions described are those in which the evidence of this action is peculiarly striking. The entire clinical evidence, however, is based upon four years' experience with about 2000 cases. All varieties of bacterial infections have been dealt with, ranging from tuberculosis in the human being to distemper in the dog. I hope to describe in detail this form of treatment of many diseases in the near future.

In conclusion, when he masters the slight though numerous technical difficulties of the procedure described, I am sure that the clinical bacteriologist will find at his disposal a rapid and most effective antibacterial remedy. Also I hope that the research laboratories will find data to investigate in the scientific problems that are involved.

ANTHELMINTIC WORK IN EGYPT.

BY H. B. DAY, *M.C.*, M.D., F.R.C.P. LOND.,
DIRECTOR, MEDICAL UNIT, ROYAL SCHOOL OF MEDICINE, CAIRO.

IN a previous communication[1] I described the establishment of a special department, termed an anthelmintic annexe, at Kasr-el-Aini Hospital, Cairo, for the out-patient treatment of the worm infections that are so rife in Egypt. The success of this undertaking has led to a large development of the system, so that at present there are five other annexes at work in the larger towns, one of which is supported by local funds. The object of the present article is to describe in brief outline the clinical work done and the results of further experience; an official report with statistics is in course of preparation by the Public Health Department.

Where space permits the annexe is erected in the grounds of a general hospital, but always has a separate establishment under the charge of one or generally two special medical officers. Each annexe consists of marquee tents or light shelters, arranged as waiting rooms, latrines, treatment room, clinical laboratory and shelters in which patients rest after treatment; accommodation for women and children is kept distinct. The shelters occupy the greater part of the annexe and are furnished with stretchers on trestles.

The patients are either sent from the neighbouring hospital or come of their own accord. The popularity of treatment is shown by the large and increasing attendance; over 50,000 new patients came last year, the largest annexe taking more than 10,000. Of these some 10 to 15 per cent. are females, and about 15 per cent. are children under 12 of both sexes. Males largely predominate, since they are more exposed to repeated infection. On admittance the general condition of the patient is noted and specimens of the dejecta secured for microscopical examination. When definite anæmia is present (easily determined by the use of Tallquist's card hæmoglobinometer), the patient is at once given a dose of vermicide, provided the alimentary conditions are favourable for its action. Otherwise he is directed to return for treatment, the next day if possible. At the second visit the results of the microscopical examination is known and appropriate treatment instituted. Negative cases and patients unsuitable for out-patient treatment are thus eliminated. Of the positive cases the great majority are infected with bilharziasis or ankylostomiasis.

Bilharzial Cases.

Treatment.—The routine treatment is a course of intravenous injections of antimony sodium tartrate, given three times a week till 12 doses have been given; this occupies four weeks. For an adult man the maximum dose is usually 2 gr., which is attained at the third injection; the initial dose is 1 gr. and the ordinary full course totals 22½ gr. of the drug. For women and adolescents smaller doses are often advisable, usually 1½ gr.; for children under 10 years 1 gr. is generally a sufficient dose. After each injection the patient lies down for an hour or two in the shelters, and is warned to avoid exertion for the rest of the day.

Control.—The effect of the treatment is tested by a routine microscopical examination of the excreta on the day when the eleventh injection is given, some 24 days after the commencement of treatment. Sometimes no ova are to be found, generally a few, occasionally some hundreds. These ova should all be unmistakably dead, showing up black or brown under the microscope, and in such cases the next injection (the twelfth) will complete the course. Only a small proportion of patients, 2 to 4 per cent., show a few ova yet alive and require more than 12 injections to ensure a cure. I have only met with one case in which the ordinary course had little apparent effect on the ova; a shorter course is often sufficient to cure slight cases, especially of old standing. In the case of patients, such as children, who are given reduced doses, it is advisable to test the efficacy of the dose employed earlier. After a fortnight's course, from 25 to 50 per cent. of the ova should fail to hatch in water.

Results.—While all observers agree on the beneficial results of antimony treatment, some report failure in a considerable proportion of cases. But before discussing the causes of failure it is necessary to distinguish between the clinical and the vermicidal results. Thus in many instances a few injections will remove the symptoms, while a prolonged course, amply sufficient to kill the ova and parent worms, will not cure a patient whose symptoms are due to secondary infection or papillomatous growths. The only criterion of specific cure of bilharziasis is the permanent disappearance of living ova; for months afterwards some dead ova may be found. The mere cessation of hæmorrhage is worthless as a test; in untreated cases there is often no blood lost, and a clear-looking sample of urine will often be found to contain far more ova than a specimen showing profuse hæmaturia.

Causes of Failure.—Judged on the vermicidal result, the usual cause of failure is insufficient treatment. This is commonly due to the early relief of symptoms, so that the patient, deeming himself the best observer, ceases attendance after a week or two.

On re-examination some months later, little or no effect of the treatment may be found. In the annexes it is to be expected that a considerable proportion, often more than half, of the patients fail to take a full course. Much depends on the punctuality and personality of the medical officers, and it is a compliment to Dr. Yassa Mitgalli, who has charge of the Kasr-el-Aini annexe, that over 63 per cent. of his bilharzial patients took the full course. Irregular attendance of patients is often responsible for unsatisfactory results. Should a patient absent himself for a week or two after a short course of four to six injections examination of the urine on his return will generally show absence of living ova. But this short course is rarely lethal to the parent worms, as we have been able to prove by post-mortem examination, so that a cure can only be assured by further treatment.

The following case is an example of failure due to infrequent attendance :—

Time in weeks	1	2	3	4	5	6	7	8	9	10
No. of injections per week ..	3	1	1	2	0	3	1	1	0	3

Here 15 injections, totalling 28½ gr. of antimony tartrate, were given in the course of ten weeks. At the finish three dead ova were found in the sample specimen ; five weeks later three living and 25 dead ova. Five months from the end of treatment 200 living ova were counted in the specimen passed. Experience proves that it is necessary to maintain a sufficient concentration of the drug in the circulation for three to four weeks to secure death of the worms. When reduced doses are given it is advisable to test their effect on the ova during treatment, as mentioned above. Should a patient exhibit some intolerance to antimony, the dose can safely be reduced with little risk of jeopardising the cure. In such cases it appears that the system is saturated, and the worms suffer more than their host.

Clinical Results.—The clinical results of specific treatment are excellent in the early stages, but cases complicated by severe sepsis or marked structural changes are little benefited. A few very early cases with initial fever, œdema of the legs, swelling of the liver and spleen with high eosinophilia have come into hospital, and it has been possible to watch the rapid regression of these signs on treatment with antimony.

Bladder.—These cases form the great majority and do very well unless much pyuria from bacterial infection be present.

Ureter.—On account of the small calibre of the ureters, bilharzial disease readily produces partial obstruction and the late effects are disastrous.[2] Any case of renal colic showing even the slightest signs of bilharziasis should receive specific treatment, as only the earliest stage is curable.

Intestine.—Cases suitable for out-patient treatment do well. Those complicated by pellagra, septic dysentery, extensive papillomatous growths, or infiltrations are admitted to the wards, but are often refractory to all forms of treatment.

Liver.—Bilharzial cirrhosis is by no means an uncommon complication of *B. Mansoni* infection. In its later stages little benefit accrues from specific treatment : when the general infection has been treated, splenectomy is advisable if the enlarged spleen causes much local discomfort.

Precautions.—To avoid undue risks, proper selection of cases is indispensable. The more obviously unfit are automatically excluded, since they are unable to make the journeys to and from the annexe. Routine examination of the urine detects cases of renal disease, usually pyonephrosis from ureteral obstruction. Anæmic patients are first examined and treated for ankylostomiasis before treatment for bilharzial disease is instituted. Some deaths of apparently healthy persons under treatment with antimony have occurred. Reports indicate that intercurrent disease, especially attacks of fever, is an important source of danger. Unexpected bouts of pyrexia are not uncommon among our patients of the lower classes, but are rarely the subject of complaint. Thus an out-patient may come for his injection when suffering from influenza or other malady, conditions which render the use of antimony most undesirable. In other cases signs of cardiac irritation or depression may appear as toxic symptoms. Unless fresh solutions are employed, bacterial contamination may cause a considerable rise of temperature after injection. The precautions are : to use only fresh solutions, to feel the pulse, and to inquire after the general condition of every patient before each injection, taking the temperature should suspicion arise. After the injections have been given, the medical officer makes a round of the shelters and examines any patient who shows bad after-effects. A note is made on his card for subsequent warning. A certain number of patients develop jaundice ; this is infrequent—less than 1 in 1000. The jaundice may appear during the course, but more often a week or so later. It closely resembles the salvarsan variety and has been of a mild nature.

Treatment with Emetine.—It appears that previous to Christopherson's publication on the use of antimony[3] the beneficial action of emetine on bilharziasis was known in Cairo, and the drug used as a secret remedy. The high cost of emetine has militated against its routine employment for the thousands of cases treated annually in the annexes, but for certain patients it is invaluable, and the drug is preferred to antimony by some practitioners. We use emetine for the following classes of patients : (1) young children and others whose veins are too small or inconspicuous for intravenous medication ; (2) cases of intestinal bilharziasis complicated by amœbiasis ; (3) patients exhibiting intolerance to antimony ; (4) in the wards for cases complicated by advanced hepatic or renal disease. In general the course and doses employed have been similar to those of antimony tartrate. Slightly larger doses may be used, but are usually provocative of toxic effects, the patients complaining of heaviness and numbness of their limbs, symptoms which are not infrequent with the smaller doses towards the end of the course. An intensive course of daily injections in ten doses of 1½ to 2 gr. has been used by Erian[4] and Tsykalas[5] with success. On trial of this method Dr. Mitgalli found that severe toxic symptoms occurred in most patients, the neuritis being followed by ulcerations of the lips and tongue in several cases. At the end of this intensive course living ova were still found in the urine, but disappeared later. Patients seen after an interval of five months have shown a complete cure, proving that emetine has a cumulative effect and kills the worms as soon as the ova. With antimony, on the other hand, a short course will kill the ova in a similar way, but not all the worms. In the important work of Fargher and Gray[6] on the chemotherapy of antimony, it is shown that potassium antimony tartrate is two and a half times as toxic and the sodium compound one and three-quarters times as toxic as the lithium compound, whereas the antimony content is much the same in each. The drugs were tested by intravenous injection on mice. I have recently tried the effect of the lithium antimony tartrate, kindly prepared by W. M. Colles, Professor of Physical Chemistry at the Medical School. This compound proved to be fully effective in the treatment of bilharziasis, but it is too early to say that it is less toxic to man than the salts usually employed.

Ankylostoma Cases.

About 40 per cent. of the patients belong to this category, the proportion varying at the different establishments. Patients suffering from anæmia, both new and old, are seen first, as each treatment takes a few hours. The doctor counts the pulse, takes a drop of blood on absorbent paper, and enters its hæmoglobin value (according to Tallquist's scale) on the treatment card. Should the anæmia be severe or the general condition unsatisfactory, the patient is urged to enter the general hospital. In ordinary cases the medical officer directs that an anthelmintic be given at once, unless a meal has been recently taken, without waiting for a report on the dejecta. This is done to save time, for it is found that ankylostoma

patients as a class are irregular and slack in attendance. As the great majority of the patients have intestinal parasites of one sort or another a single treatment is of value.

Laboratory Diagnosis.—Though severe anæmia is almost invariably due to ankylostomiasis in Egypt, the identification of the infection by microscopical examination of the stools is always desirable and is necessary for the control of treatment. In the majority of cases the test is needed to confirm the clinical diagnosis, while in an important minority it shows some other infection—such as chronic dysentery—to be responsible for the patient's symptoms. For unless diarrhœa be excessive or hæmorrhage occur, the average patient pays scant attention to his stools. The specimens of fæces collected are divided for examination in two classes: (*a*) liquid stools and those containing blood, (*b*) those of normal appearance.

(*a*) Abnormal stools should be the first examined at the laboratory. The presence of blood and mucus more or less separate from the main dejecta is characteristic of bilharzial disease of the intestine, and the spined ova will be found in this exudate. Other stools may contain much pus, often many flagellates, and the origin of the dysentery be thus obscured by secondary infections. Suspicious stools must be searched for amœbæ; hence the advisability of examining such specimens as soon as possible, before the amœbæ become inactive. Cysts are much more troublesome to identify, and, in the case of *Entamœba histolytica*, need the addition of iodine solution to bring out their structure.

(*b*) In the ordinary stool the search for ova is simplified by the routine employment of the flotation method, the mechanical process being performed by an orderly. Although the very simple method used[1] is by no means perfect[7] it represents a great advance on a direct smear. All laboratory findings are entered in the space provided on the treatment card and the numbers of ova present roughly indicated by the addition of + signs.

Treatment.—Carbon tetrachloride is the best remedy and is given in doses of 3 to 5 c.cm., followed by a purge after two hours. As a rule two treatments will remove almost all the worms. When this drug is not available, oil of chenopodium is substituted; it is given in gelatin capsules, each containing 0·5 c.cm. To an adult two capsules are given at once; the patient lies down and after one and a half hours another capsule is administered, followed by a dose of castor oil after another hour. When the treatment is finished the patient is allowed to take food and go home. He is instructed to return a week later, fasting, and to bring a bottle for medicine with him. For the convenience of patients who live some distance away, sleeping accommodation is provided, so that they may come the evening before. In cases proved positive on stool examination, the anthelmintic is repeated on two subsequent visits, the patient taking iron and arsenic mixture or pills in the intervals. At the third administration the hæmoglobin value of the blood is again determined and the stools re-examined for ova. So long as ova are found, weekly treatments are continued. As a rule two treatments with carbon tetrachloride or three with oil of chenopodium are sufficient to expel all but a negligible number of the ankylostomes. Hæmatinic treatment is generally essential for a satisfactory recovery from the anæmia. The conclusions given in a previous study[8] have been fully confirmed on further experience. Thus the steady rise of Hb value following the expulsion of worms is an excellent index of successful treatment. The patient should be urged to continue taking the iron mixture and warned that recovery of his strength will be gradual. In many cases a weekly injection of sodium cacodylate will further improve the anæmia and encourage attendance, as most patients have a firm belief in the efficacy of the "needle." A failure of the case to respond to efficient treatment is a sign of an incomplete diagnosis, and some complicating disease should be searched for. When ascaris or tænia ova are found on examination of the stool, it is customary to supplement the treatment described by giving the appropriate remedies. Patients found suffering from chronic amœbic or bilharzial dysentery receive treatment at the annexe; negative cases are referred to the general hospital.

In concluding this brief survey I wish to express my obligations to the staff of the Public Health Department, whose work has been crowned by so large a measure of success.

Clinical and Laboratory Notes.

A CASE OF *B. PYOCYANEUS* INFECTION CURED BY VACCINE TREATMENT.

BY H. RONALD CARTER, M.D. BRUX., M.R.C.S. ENG.,
PHYSICIAN TO INFANT WELFARE CENTRE, KENSINGTON.

THIS case of *B. pyocyaneus* infection, which had some clinical resemblance to glanders, is of interest in that *B. pyocyaneus* usually infects the alimentary tract.

A married woman, aged 63, had been a cripple from rheumatoid arthritis for 20 years. The pyocyaneus infection had no connexion with her arthritis. On Oct. 5th, 1920, whilst being pushed along in her wheeled chair she suddenly felt that she had a "cold in the head." When she got home her nose was "very stuffy," and the next day she had developed a "feverish cold," which persisted and got worse.

Condition on Examination.—I saw her on the 15th, when there was a clear mucous discharge from the nose, sometimes blood-stained. Temperature 102° F. I could find nothing else to account for the temperature. The nose was douched with a saline lotion, and this often brought away large blood-clots from the posterior nares. There was considerable pain and swelling in the nose accompanied by frontal headache.

On the 28th a tense, brawny swelling occurred over the right parotid, with intense pain. I made a free incision and clear fluid escaped, which in a day or two became greenish in appearance. As the patient was in great pain I gave her a hypodermic injection of morphia in her left forearm; the next day the same brawny swelling appeared over the whole of the extensor aspect of the left forearm.

Operation.—I asked Mr. Zachary Cope to see the case, and he cut into the swelling and found no pus, but a complete necrosis of the subcutaneous tissue, which he proceeded to remove. About a week after this operation a greenish discharge made its appearance. The wound healed up in two months, when suddenly she developed acute pain and discharge from both ears.

Vaccine Treatment.—The patient was becoming rapidly worse, so I asked Dr. John Freeman to see her; he admitted that the case bore some clinical resemblance to glanders, but fortunately he was able to isolate the *B. pyocyaneus*, and glanders was not present. An autogenous vaccine was made, and I began giving a dose of 2 millions, but this proved to be far too strong. The vaccine had to be considerably diluted, and I found I got the best results with a dose of about 15,000. This small dose had to be cautiously increased, as any overdose made the patient very ill for a week. I continued to give the vaccine for two and a half years; latterly I was giving 100 million doses without producing any reaction. These large doses were well tolerated if given not oftener than once a month. The patient is now perfectly well; her arthritis, of course, remains the same.

I feel a case like this is convincing as to the adequacy of vaccine treatment. The question of dosage, however, is of practical importance, because on several occasions I had the greatest difficulty in persuading the patient and the rest of the family to continue the treatment after a very violent reaction had occurred. The laboratory expert cannot unfortunately tell us what the minimum dose in a particular case should be; the clinician must find this out for himself.

Kensington, W.

A CASE OF FOOT-AND-MOUTH DISEASE.

BY A. HUGH GIBBON, M.D. BRUX.,
LATE MEDICAL OFFICER OF HEALTH, BURY ST. EDMUNDS.

I WILL preface this note of a case of foot-and-mouth disease with the definition given by Prof. J. McFadyean, in Clifford Allbutt's "System of Medicine." "Foot-and-mouth disease is an acute febrile condition characterised by the formation of a vesicular eruption, the most constant seats of which are the buccal mucous membrane and the skin of the digits."

The patient, aged 35, was a tailor by trade. The attack occurred some years ago during a severe outbreak of foot-and-mouth disease in Norfolk. The patient had many farmers as clients and possibly became infected on his wrist while handling some client's clothes with saliva on them. The condition first appeared as a herpetiform eruption on lips, which gradually spread to buccal and lingual mucous membrane.

Foot-and-Mouth Disease.

FIG. 1. FIG. 2.

Showing vesicles on hands and feet of patient. Fig. 2 is a clearer representation of the condition.

Within from 24 to 48 hours bright red spots appeared on hands, arms, feet, and legs (Figs. 1 and 2), principally on the extensor surfaces, as far as the elbows and knees—though there were a few scattered ones on the soles of the feet and on the thighs. These gradually enlarged, becoming vesicular. Simultaneously, large vesicles developed all over the inside of the mouth, cheeks, and lips, and must have spread over the pharynx, as there was considerable difficulty in swallowing. The tongue, the whole surface of which was covered, had eight or nine large separate vesicles on it, the margins of which must have met, so that after these had subsided definite scars were left where the edges had been.

Simultaneously, conjunctivitis appeared (with much photophobia) developing into an acute purulent ophthalmia. There was also a purulent, very offensive nasal discharge. There was an increased salivary secretion, or an appearance of the latter, which might have been due to the difficulty in swallowing. The temperature rose slowly and steadily to 103° F. with very slight morning remissions, and as gradually subsided.

The patient's chief complaint, apart from the discomfort of the eyes and mouth and tenderness of the extremities, was that "he could not smoke, as it made his eyes and tongue smart too much." He "did not feel ill in himself." The total duration of the attack was about three weeks. The fluid in the vesicles was gradually absorbed, only one on the right wrist showing any signs of suppuration, while those in the mouth burst, leaving a bright red, very tender base.

The patient made an uninterrupted recovery, the only complications being that as the nails grew up there was a deep sulcus, showing symmetrical destruction of the matrix at the base of the nails, both of hands and feet; also—two years after the attack, when patient was last seen—there persisted a very definite, fine, fibrillary tremor of the fingers, similar to that seen in Graves's disease.

A CASE OF CHORION-EPITHELIOMA.[1]

BY J. P. HEDLEY, M.CH. CAMB., F.R.C.P. LOND., F.R.C.S. ENG.,
OBSTETRIC PHYSICIAN, ST. THOMAS'S HOSPITAL.

THIS case of chorion-epithelioma is of interest as it presents several unusual features.

The patient, a woman aged 35, had been married three years, and had had no child. She had lived in India for three and a half years before returning to England in November, 1923. Following are the details of the case before her departure from India:—

History.—She had always had slight irregularity of her periods, which were occasionally very painful; about nine months before marriage she began to have periods every three weeks. The periods at the time of marriage remained unchanged until August, 1922, when they began to be rather more frequent. About Christmas of that year the patient began to have bleeding every ten days followed by a pinkish discharge, which went on until the next bleeding in ten days or so. In about the middle of April, 1923, one night the patient suddenly had a very severe pain in the lower abdomen; she nearly fainted, and had to take brandy and have hot-water bottles applied. Next day she had rather severe vaginal bleeding. About ten days later she had a bad hæmorrhage that lasted a few hours. She was away from home April 29th to May 3rd, and had attacks of pain in the lower abdomen of increasing intensity, with vaginal bleeding during that time. On her return on May 4th marked tenderness of lower abdomen was detected, and by vaginal examination ill-defined masses could be felt on both sides of the uterus, which were very tender. The uterus could not be outlined; there was no mass in the pouch of Douglas; the temperature was 100° F.

Diagnosis.—As the patient had had cystitis some months previously a diagnosis of salpingitis was made. She was treated by rest in bed and hot douches, ichthyol and glycerine plugs and application to the abdomen for a few days with some improvement, but on the 9th the patient looked ill and could not move on account of intense pain at the lower abdomen. At this time there seemed to be less swelling to the left, but on the right the tender mass reached up to the level of the umbilicus; there was a leucocytosis of 15,000.

Operation.—Colonel G. D. Franklin was called in, diagnosed appendix abscess, and operated on the 10th. When the peritoneal cavity was opened the swelling was found to be due to blood, not pus; the incision was elongated, and a large left tubal gestation, still bleeding, was brought up into the wound. The mass was ligatured off with part of the ovary, and clots removed from the peritoneal cavity; it appeared to consist of nothing but laminated clots with the appendages. The uterus was found slightly enlarged. The abdomen was closed in the usual way. The patient

[1] A case described at a meeting of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine, on Feb. 7th, 1924.

was relieved of all pain and made a rapid uneventful recovery.

Course of Case.—On June 7th, one month after operation, a vaginal examination was made; a fleshy mass in which a spicule of bone could be felt was found protruding through the os, which was about 1 inch dilated. The patient then said that for a few days she had felt pain in defæcation and had always to sit down very gently. The next day—under morphia—the mass was removed by ovum forceps and flushing curette; the uterus was gently curetted, and seemed to be empty and not more enlarged than in a two months' pregnancy. The fornices were clear. The mass removed was about 3 inches in length, and contained a few definite spicules of bone, but nothing could be recognised as any definite part of a fœtus. It was thought that the pregnancy must have been in the uterine end of the tube and expelled into the uterus where the fleshy mole had formed.

The patient was able to go to the Hills six days later, and there she picked up rapidly, put on flesh, and felt very well. Her periods occurred on June 27th, July 21st, and August 16th; they were increasingly painful, but there was no excessive loss. The August period started normally, but after the first day the discharge became watery and pink in colour, and persisted until Sept. 2nd, when she was examined again and a smooth round mass was found protruding from the external os. Four days later, under an anæsthetic, the mass was found to be the size of a goose's egg and attached to the anterior left wall of the uterus by a pedicle about 1 inch in diameter. The pedicle was divided, and a rough area left at its site of attachment, but otherwise the uterus was empty and the wall normal. Pure carbolic was applied; later the patient was given ergot and hot douches, and the uterus contracted down.

It was thought that this tumour was probably a chorion-epithelioma, and it was sent to Bombay for examination by a pathologist. He reported that the mass had a structure resembling placenta; no malignant change could be found, and there was nothing suggesting deciduoma malignum. The patient was up six days after this operation apparently well, but two days later, on Sept. 14th, she had severe pain in the left side of the abdomen low down; this persisted until the 20th, when she was again seen by Dr. Helen M. McMillan, who found tenderness in the pelvis; there were also diarrhœa and pelvic pain. During the next 24 hours there were four stools, which contained blood and mucus. Emetin and sodium sulphate were given, and all bowel symptoms quickly disappeared, but the uterus and surrounding parts were very tender.

On Oct. 9th, just before patient went to Bombay to sail for England, it was noted that her temperature varied between 99°–100°; she had some indigestion, and at times had pain on defæcation. The uterus was somewhat enlarged and still rather tender, a hard ridge was felt between the uterus and the stump of the left appendages; the stump itself was very distinctly felt. The right fornix and Douglas's pouch were clear. On the 13th profuse vaginal bleeding started, lasted for three days, and was followed by a pink discharge. During the voyage from India this discharge continued, the temperature ranged from 99°–100°, the pain in the lower abdomen was continuous and very severe, and there was added to it very acute pain low down in the back.

Condition on Arrival in England.—On arrival in London on Nov. 6th a hard, fixed nodular mass was felt in the abdomen, reaching up to the umbilicus and out on each side to the anterior superior spines. There was no dullness in the flanks and no evidence of any involvement of the lungs. There was very great frequency of micturition. On vaginal examination a large polypoid mass was found occupying the vagina. The lip of the cervix could be reached surrounding the pedicle except on the left side.

Final Operation.—On Nov. 8th I examined the patient under an anæsthetic, when the complete ring of cervix was felt, but the pedicle seemed to be attached very low down on the left side. I removed the polyp and gently curetted the cervix; it was then clear that the abdominal mass was fixed. A circular rough area about 1 inch in diameter was seen where the stalk of the polyp had been divided. This area reached to within about ¼ inch of the external os on the left side, and the opening of the undilated part of the cervical canal could be seen to the right of it. Into this the sound could be passed 2 inches. In the recto-vaginal septum a circular thickening about 1 inch in diameter and ¼ inch in thickness was felt separated from the cervix by about ½ inch of apparently healthy vaginal wall.

Fatal Termination.—After this operation the patient lived for three weeks; she got rapidly thinner, but the frequency of the micturition ceased, and there was no vaginal bleeding or discharge. Eleven days before death complete intestinal obstruction developed, which caused great distension of the upper part of the abdomen, but no increase of the tumour or change in the other signs in the abdomen could be detected. For the last five days there was suppression of the urine. The abdominal distension caused great embarrassment of respiration, but there was no other evidence of involvement of the lungs. The patient died on Nov. 28th of what the nurse described as suffocation.

The polypoid tumour removed from the vagina is roughly heart-shaped and measures 3 by 2¾ by 2 inches. It is a solid tumour with partly gangrenous exterior. The cut surface shows a narrow border of reddish tissue on the outside which surrounds a large firm pale area extending to the lowest limit of the mass. Two cysts are present in the mass, and a large hæmorrhage. There is some calcification in the pale area.

Dr. L. S. Dudgeon, who examined the tumour for me, found chorion-epithelioma in all the sections. He reported that there were wide tracts of necrosis and hæmorrhage; inflammatory reaction in the necrotic areas, especially at the limiting zones. One portion shows a firm fibrous tissue enclosing large cells, in some cases multi-nucleated, and a loose tissue with large multi-nucleated cells scattered all through. Two or three tracts of "epithelial" tissue are present in most of the sections.

The points of especial interest in the case seemed to me to be: (1) That the chorion-epithelioma followed an extra-uterine gestation, but appeared as an intra-uterine growth; (2) that three large polypi were removed per vaginam from the uterus between June and December, and in each case the area of attachment to the wall was of about the same extent; (3) that the periods returned, and were regular and not excessive between the removal of the first and second polypi; (4) that what appeared to be spicules of bone were found in the first, and calcified areas in the third polypus; (5) that there was no evidence of ascites, though the main mass of growth seemed to be intraperitoneal.

I am indebted to Dr. McMillan and Colonel Franklin for the details of the case before the patient's departure from India.

A CASE OF TRISMUS IN ENTERIC FEVER.

BY JAMES S. ANDERSON, M.D. ABERD., D.P.H.,
SENIOR RESIDENT MEDICAL OFFICER, CITY HOSPITAL, ABERDEEN.

IN view of the rarity of the condition, the following case has been thought worthy of record.

A male, aged 17, came of a family with a marked history of mental instability on the mother's side. He was admitted to hospital on the third day of his illness, having contracted the disease from his sister who had already sickened of it. The onset was acute, with marked prostration. For the next fortnight the temperature remained continuously between 101° and 105° F., the pulse-rate varying between 110 and 124. The blood gave a pure culture of *B. typhosus*, and an agglutination of the same organism to 1 in 30. On the seventh day of the disease low muttering delirium set in, while carphology and subsultus tendinum were invariably present. Hydrotherapy, with ice cold water, only partially controlled the fever, and sleep, usually of short duration, could only be obtained by intensive administration of chloral hydrate and ammonium bromide. For five days the delirium was very marked, and then gradually disappeared. On the twenty-third day delirium of suspicion was noted, but only for one day. Bowel hæmorrhage occurred between the fifteenth and twenty-first days, intermittent in character, and never amounting to more than a few clots. On the twenty-seventh day symptoms of periostitis developed in an unusual position—the right wing of the sacrum being involved. The temperature, which had almost reached normal, simultaneously began to rise. This region was explored on the thirty-third day, and from the pus a pure culture of *B. typhosus* was also obtained. Meanwhile, on the thirtieth day, trismus appeared. Tonic, apparently painless, contraction of the jaw muscles gradually increased in intensity, and was accompanied by difficulty in deglutition and tonic contraction of the extremities, and of the muscles of the back and the nape of the neck. The trismus was constant, and at most the teeth could only be separated to the extent of a quarter of an inch, but there were no convulsions typical of tetanus. In view of the possibility of meningitis, lumbar puncture was performed on the thirty-first day, when a slight increase of pressure of the cerebro-spinal fluid was noted. The cytology and chemistry of the fluid were normal, while the culture

remained sterile. Prior to the development of trismus no broken sores were visible on the body, and no history of recent injury was present. No urinary changes were detected. Tonic contracture remained a constant feature, trismus being so marked at times that the patient could not separate the teeth. Death occurred on the thirty-eighth day of the disease.

According to Curschmann,[1] the occurrence in adults of trismus and a tetanus-like condition in enteric fever is a rare event, and is an expression either of a most profound toxic action upon the central nervous system, or of especially severe complications.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Feb. 25th at 11, Chandos-street, Cavendish-square, W., Dr HERBERT SPENCER in the chair, when a discussion was held on the

Treatment of Fibroids of the Uterus.

Dr. CUTHBERT LOCKYER, opening the discussion, said that it had been estimated that uterine fibroids could be demonstrated in from 10 to 25 per cent. of all women, and that Frank had stated that 45 per cent. of uterine fibroids required treatment. If the possessor of the tumour was conscious of its presence the growth should be kept under periodic observation. He would advise radiologists who favoured submitting a symptomless fibroid to X rays to let sleeping dogs lie.

Operative Measures.

Uterine fibroids requiring treatment might be dealt with by palliative or by curative measures: radiotherapy could be classed under either head according to taste. He would, however, discuss surgical methods before dealing with radiotherapy. The routes of surgical attack might be abdominal or vaginal. Vaginal procedures included the removal of pedunculated fibroids from the body of the uterus and the cervical canal, hysterotomy, and in a certain number of cases hysterectomy. Abdominal operations included myomectomy, supravaginal amputation, and total hysterectomy.

Myomectomy.—Strenuous efforts were being made to popularise this apparently safe and ideal operation. The clear indications for its use were to preserve for the non-gravid woman a functional uterus, and to cope with a surgical emergency in the gravid state. He believed that after deep myomectomy with the opening up of the uterine cavity which was frequently necessary, convalescence was by no means smooth, and morbidity was increased. W. Mayo's statistics on myomectomy gave valuable information concerning subsequent fertility. Of 741 myomectomies (617 abdominal, 124 vaginal), 59 afterwards became pregnant, 44 children were known to have been born, and 15 women were pregnant at the time of reporting. Nineteen of these myomectomies were performed during pregnancy, and 23 women previously sterile were known to have one child or more after operation. In his own cases (continued Dr. Lockyer) he had performed 545 major operations for fibroids; 33 of these, or 6 per cent., were abdominal myomectomies, and there was one death, due to the presence of umbilical hernia and massed adhesions of the small bowel. He submitted that myomectomy during pregnancy was well tolerated by the gravid uterus, that it was not indicated for fibroids lying well up in the abdomen and causing no symptoms, and that in the presence of severe bleeding it made uncertain the possibility of saving the gravid uterus. In wisely selected cases, however, it had proved satisfactory.

[1] Curschmann: Nothnagel's Encyclopædia of Practical Medicine English Ed., 1902, p. 264.

Supravaginal Amputation or "Subtotal Hysterectomy."—This operation had divided gynæcologists into two schools—those who advocated its abolition from classical technique, and those who wished to retain an operation which had done more than any other to give repute to surgical treatment of fibroids. He considered that some surgeons went too far in refusing to admit that the subtotal operation had still a place in surgery. The risk of leaving behind a malignant or potentially malignant vaginal cervix could with care be reduced to a minimum. In 479 abdominal hysterectomies for uterine fibroids he had performed the supravaginal operation 284 times with five deaths—a mortality of 1·76 per cent.

Total Hysterectomy.—This operation was older than the subtotal one; the relative risks of the two were hard to determine, for (1) many total hysterectomies were done because the operator had no choice, having to remove the uterus for a large fibroid—as he should do in all septic cases—and (2) the same operator might use the method in easy cases, or whenever the circumstances did not prevent him from so doing. He would thus have two totally different types of case in his statistics of the same operation. A personal series of total hysterectomies numbered 195 with three deaths (1·54 per cent.) and a personal series of subtotal operations numbered 284 with five deaths (1·76 per cent.). Miles Phillips's results and his own together seemed to show that the primary risks of the two operations lay within quite small limits, the difference being slightly in favour of the subtotal operation. Before investigating the point he had imagined a higher relative mortality for the total operation. This view he no longer held, but time had not yet permitted him to redress the balance in the numbers of operations in his own practice.

The Fate of the Ovaries.

Hysterectomy for fibroids being more commonly performed on women over the age of 40, it might be argued that the sacrifice of both ovaries was unimportant, but he believed that even above that age it was better to conserve one if they were healthy. Phillips had stated that he had once taken pains to conserve ovaries, but had found that cases from whom all ovarian tissue had been removed gave the most perfect results. Prof. Blair Bell had said that when conservation of the normal ovary was not feasible, owing to infection of the appendages or other reasons, he always made an ovarian graft in women under 40 years of age. This was (continued Dr. Lockyer) probably the practice of most of those present; he believed that the Manchester, Sheffield, and Birmingham schools stood alone in advocating routine castration during hysterectomy for fibroid.

Radiotherapy.

The value of radium and X rays in checking hæmorrhage was now universally admitted. Hæmorrhage was the most prominent symptom of uterine fibroids. But treatment by radio-active bodies was not without risks in this connexion; quantitative dosage had yet to be attained, and there seemed more hope for radium than for Rontgen rays in respect of scientific measurement of dosage. Surgeons who had studied pelvic pathology realised that the uses of radiotherapy for fibroids of the uterus were confined within extremely narrow limits, variously described as from 17 to 5 per cent. of all cases. His own experience with the use of radium in the treatment of hæmorrhage had been in cases of chronic metritis, and the results had been favourable. In conclusion, he would, if asked as to the proportions of cases of uterine fibroids requiring removal, reply that 55 per cent. of all fibroids needed no treatment at all, 35 per cent. required removal, and the remaining 10 per cent. should be dealt with by radium.

Discussion.

Sir GEORGE BLACKER thought that most of those present would agree with much that they had heard

from Dr. Lockyer; fibroids which gave no trouble required no surgery, but when surgery was necessary, he had removed tumours weighing 2 lb. without damage to the patient. It had been said that removal should be performed to promote pregnancy, but he believed that the majority of women having fibroids were already sterile, and he would rather attend a woman with half a dozen fibroids than one with half a dozen scars of previous myectomies. Personally, he found that the advantages of total and subtotal hysterectomy were evenly balanced, provided the operation was carried out by expert hands; but subtotal hysterectomy was more difficult, and if it were practised by all sorts of operators throughout the country the mortality would rise above that of women dying from cancer of the body of the uterus after the cervix had been removed. The ovaries should never be removed in young women; such castration was unnecessary, the whole object of hysterectomy being to leave healthy organs behind. He considered that radium treatment had many advantages in a very small class of case, namely—tumours of small size, without complication of any kind. He had abandoned X ray treatment some years before, and when using radium was always careful to give an anæsthetic, to perform careful bimanual examination, to explore the interior of the uterus, and to carry out curettage. Patients reacted quite differently to radium treatment as regards dosage and time required. After-treatment was simple; the radium treatment could be carried out in a week-end, and in the light of the problem of waste of public money, owing to protracted periods spent by patients in hospital, this rapid treatment should be useful. He had treated 37 patients with fibroid tumours during the past few years; of 23 of these, treated before June, 1922, 21 were completely cured. One of the others had a sarcoma of the uterus. Of the 14 treated since, 12 were apparently cured.

Mr. T. G. STEVENS asked what was the result of the treatment on the fibroids themselves. He had seen a case treated by X rays, in which the patient appeared at the end of four years with a large sarcoma of the cervix, and had read of other cases. Patients treated in the West End of London or in the consulting districts of large cities might be safe enough, but what would happen to the cases of fibroids treated all over the country by inexperienced men? He had found a patient who was being treated with radiation and had a large ovarian cyst; fortunately, the instrumentation had been weak.

Dr. H. WILLIAMSON believed that present knowledge was only of temporary value; they knew nothing of the causation of fibroids, and it was to be hoped that in the future some histologist or biochemist would make a discovery in this direction. They aimed at leaving the uterus to function if possible. Many women with fibroids bore children, and sometimes fibroids grew so slowly as never to require treatment. Drugs had at best a very limited value in this connexion. Myomectomy offered great advantages for the leaving of a functioning uterus. He would limit the use of X rays, which had no place in the treatment of young women, or of those with large tumours, pelvic inflammation, polypi, or pregnancy. With regard to total and subtotal hysterectomy, he believed that in the virgin the uterus should be left, and in the multipara removed.

Mr. BECKWITH WHITEHOUSE confined his remarks chiefly to the results of the surgical treatment of myomata. In 16 years 438 consecutive operations for fibroids had been performed at the General Hospital, Birmingham, by Dr. Thomas Wilson and himself; in this series there were 14 deaths, a gross mortality of 3·19 per cent. During the same period 97 private patients were operated upon, with a mortality of 2 per cent. The total series therefore consisted of 535 consecutive cases with 16 deaths, a mortality of 2·9 per cent. The operation of choice was panhysterectomy, but the latter was associated with a mortality of 4 per cent. The subtotal operation, performed in about half the number of cases, had about half the mortality; it was reserved generally for large solitary myomata in single patients or sterile married women. There was no instance of carcinoma occurring in the cervical stump after subtotal hysterectomy. Dr. Wilson and he had concluded from an investigation that with total hysterectomy the conservation of the ovaries was unimportant; with subtotal hysterectomy, conservation was important if endometrial tissue also was saved; and that it was advisable to conserve both ovarian and endometrial tissue in women approaching the menopause. He had never seen a myoma disappear with radiotherapy, but had seen suppuration and intestinal adhesions resulting from use of the method.

Dr. N. S. FINZI said that radiologists depended on their gynæcological colleagues for the selection of cases suitable for radiotherapy. On the continent the majority of cases were treated by radiation—X rays or radium or both. He treated patients for three successive days, then made an interval of four weeks, and then repeated the three days' treatment twice, with a similar interval between; he had found the three series of treatments sufficient for all cases. He sometimes employed a special technique by which he gave one large dose, which caused a certain amount of discomfort and illness in some cases. The result in the fibroid was the gradual disappearance of the latter.

Mr. J. P. HEDLEY preferred operation to radiation when the fibroid was large and near the umbilicus, and when the woman was approaching the menopause. He had found radiation very useful in small tumours: it cured bleeding, and so far as he knew did no harm.

Dr. H. A. DES VŒUX, speaking from the general practitioner's point of view, said that in pre-operation days he had come to the conclusion that fibroids were not a dangerous disease. Later, he had found that when he told patients that they had fibroids they immediately ran off to a gynæcologist. He wished the gynæcologists would spread abroad among general practitioners their knowledge concerning the harmlessness of fibroids giving rise to no symptoms. Was irritation of the bladder a symptom sufficient to necessitate removal of the uterus?

The PRESIDENT said that no honest man would operate where no symptoms arose, although a small fibroid was present; but all large fibroids were degenerated, and should be operated on. He agreed with those who had spoken of the value of vaginal myomectomy and hysterectomy; abdominal myomectomy was also very useful at times. He was particularly interested in the conflicting views of the relative value of total and subtotal hysterectomy. He was glad that he had almost persuaded Dr. Lockyer to become a total hysterectomist; Dr. Lockyer's own figures showed that total hysterectomy, done in more difficult cases, had a lower mortality than the subtotal operation. Dr. Miles Phillips had actually said that total hysterectomy was better than the other. Cancer of the cervix occurred in a large number of cases after subtotal hysterectomy. In upholding the total operation, he had the support of the leading gynæcologists of Russia, Austria, Germany, and America, and he hoped that those of this country would come to give him theirs also. It was not right to use X rays and radium extensively in the light of their effects on the blood and intestines, particularly with regard to the extensive ulceration which sometimes resulted from their employment.

Dr. LOCKYER made a brief reply.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Bayer "205" and Trypanosomiasis.

A MEETING of this Society was held on Feb. 21st at 11, Chandos-street, W., Sir P. BASSETT-SMITH, the President, being in the chair.

Prof. F. K. KLEINE read a paper on his recent expedition to Africa to investigate the action of Bayer "205" on trypanosomiasis. An abstract of the paper was given in THE LANCET last week. Prof. Kleine's paper was preceded by a microscopic demonstration of various types of trypanosomes in human and animal blood, and was followed by an interesting discussion.

Prof. WARRINGTON YORKE said it was commonly believed that sleeping sickness was a very fatal and rapid disease, whereas such was not the case. It was a question whether trypanosomiasis underwent a spontaneous cure. Prof. Kleine surmised that it did, and from cases which had been studied the inference was that spontaneous cure did take place, or at all events cure resulted after one or two injections of drugs such as salvarsan or atoxyl. Some confusion, he continued, had arisen in the consideration of sleeping sickness in Africa. Of the two types caused respectively by *T. rhodesiense* and *T. gambiense*, the latter was further subdivided into (*a*) a severe type of disease, and (*b*) a mild epidemic form found in West Africa. Of 35 cases of the mild infection noted in 1913, 24 were still alive ten years later. It was the opinion of the natives that the disease had simply died out. He quoted Dr. Lyndhurst Duke's opinion that the transmission of the disease was mechanical, in reply to which Prof. Kleine said that if the mechanical theory were correct, then it was inconceivable that trypanosomiasis should not have spread far beyond the bounds of tropical Africa. Prof. Yorke was not favourably impressed with the methods of the Rhodesian Government in allowing a native commission to undertake the work of investigation, but Prof. Kleine expressed himself as satisfied with the competence of the workers.

Prof. Yorke then showed a case, Mr. J., who had been cured of trypanosomiasis by Bayer "205" three years ago, and, as the patient himself testified, was now in excellent health.

Dr. G. C. LOW said that a distinction must be drawn between the infection as it occurred in natives as distinct from white men. Spontaneous cure might take place in a native, but he had never known of a spontaneous cure in the case of a white man. Bayer "205" had certain disadvantages; it was a poisonous drug and attacked the kidney. Very careful nursing was required to reduce the albuminuria.

Sir FREDERICK MOTT compared the affection of the central nervous system in trypanosomiasis to that in general paralysis of the insane. As other trypanocidal drugs he instanced tryparsamide, made at the Rockefeller Institute, and bismoxyl. He inquired if there might not be two varieties of trypanosome, on the analogy of the neuropathic and the dermopathic spirochætes, which Prof. Kleine, in his reply, admitted as a possibility.

Other speakers put forward the claims of tryparsamide and atoxyl, but Prof. Kleine reiterated his statement that Bayer "205" would seem to be the best remedy for sleeping sickness.

MEDICO-LEGAL SOCIETY.

A MEETING of this Society was held on Feb. 19th at 11, Chandos-street, Earl RUSSELL in the chair, when a discussion was held on the

Law of Nullity of Marriage.

Dr. S. HENNING BELFRAGE, who opened the discussion, described the law of nullity of marriage as a law peculiarly bound up with the practice of medicine, and stated that in dealing with the medical aspects of this law he was giving expression to a purely personal point of view. The law of nullity of marriage was based on the jurisdiction of the ecclesiastical courts, consolidated in the Matrimonial Causes Act, 1857. The principles of this law were not so much definitely laid down as traditional, and they were interpreted with increasing elasticity. Several times judges had said that the state of the law was not satisfactory; this was not surprising, since cases coming under the law had medical and surgical aspects, and there had been wide developments of science since the rules were laid down. It was doubtful if originally the rules had in view anything but visible faults of development as grounds for nullity. Any structural defect preventing intercourse was accepted as ground for the granting of a decree, but cases in which evidence of such defect appeared were exceptions rather than the rule. In a suit for nullity the medical evidence was, of course, most weighty, but the court considered itself at liberty to infer a great deal from the attitude of the parties concerned. The usual case to-day was based upon abnormality of sex functions. In these functions were concerned not only the spinal and lower brain centres, but also the higher centres, subserving imagination, will, and intellect, and subject to profound disturbance by the emotions. Next to the functions associated with food, those connected with sex were the most important in the body; according to the Freudian school the latter actually overrode the former, and formed the strongest factor of mental life. All psychologists must recognise the essential part played by sex relations in every human being.

Types of Abnormal Reaction in Sex Life.

In practice there were three variations in type of abnormal reactions of women to marriage. The first variation was where the attempt to consummate a marriage called forth resistance accompanied by emotional disturbance. These cases were called hysterical, but the word did not correspond with the psychological meaning of the term. In genuine cases these reactions were not to be controlled; they constituted a true nervous reflex of a high order. The second variation was vaginismus, a condition regarded with scepticism in legal quarters but familiar to neurologists. Here there was local pain or hypersensitivity, often severe, being the expression of a buried mental complex which the sufferer was unable to recognise. The slightest touch might set up spasm in these cases, but the real trouble lay in the mind. In both of these types a defensive mechanism was at work; fear of the husband's approach set up a partly voluntary, partly involuntary reaction or emotional disturbance, and the courts had recognised the condition as an impediment for some time past. The third variation in type was that of wilful wrongful refusal. Here the woman, if able to give any reason at all, could give no real reason; there was no question of shyness, timidity, or tactlessness on the part of the spouse, and the woman's conduct appeared in all senses unreasonable. She might plead fear of bearing children, fear of disease, &c., but such pleas were merely camouflage of a morbid mental attitude in sex matters.

Wilful Refusal a Symptom of General Instability.

Should such women be held responsible or should incapacity be inferred in these cases? Both Divorce Court and Court of Appeal seemed lately to have gone out of their way to dismiss suits of this nature. Sir Samuel Evans had upon one occasion differentiated between refusal and "steadfast persistent" refusal, and had later refused to grant a decree in a similar case. Recently the court had not required evidence of structural defect. Since the refusal arose after marriage, it was at one time held not to be a ground for annulment, but this decision had recently apparently been reversed. In one case the wife had stipulated before marriage that there should be no intercourse for six months after the ceremony; the husband foolishly agreed, the war intervened and parted the couple for some years, and when the husband rejoined his wife she persisted in wilful refusal. Lord Dunedin held that there was no plausible reason for the refusal, but inferred that the wife began with an ante-nuptial aversion, and was the victim of an invincible repugnance; he therefore granted a decree of nullity. In all

such cases the medical man would easily find evidence of instability in other aspects of life. These refusals were not wilful; they resulted from lack of will power. They were not wrongful, for the woman could not see that her attitude was wrong. He would like to see these cases grouped together as containing factors which constituted a real impediment. The mental make-up on which the conduct of these women was based was a definite departure from the normal to an extent which annulled the purpose of marriage as regarded in the eyes of the law.

With regard to the incapacity of the husband, in the majority of cases this was dependent not on faulty structure, but on faulty action; in the absence of defect the judge might infer complete incapacity. Then there arose the point of the fallibility of the medical inspector's opinion concerning the wife's virginity; the signs of habitual intercourse were evident enough, but the state of the hymen, dilatation of the vagina, &c., might fail to be conclusive. He had felt that the court sometimes demanded from a medical man more than the latter could be reasonably expected to give. He thought that it was time that a committee was appointed, consisting of lawyers and medical men having experience in divorce suits, to consider and report on the whole problem of abnormal relations between husband and wife.

The Legal View.

Mr. R. F. BAYFORD did not propose to touch upon the medical aspect of abnormality which had been so ably put forward. The discussion related to nullity qua impotence, not to the wider law relating to such questions as marriage by fraud, under duress, &c. One subject which had not been touched upon was that of nullity of marriage on the ground that one party was incapable at the time through mental trouble. The law concerning nullity through incapacity to consummate marriage seemed to him to be simple and clear. He had been unable to find any real difference in the law as expounded during the past 200 years; the principle seemed clear, although it had been differently applied in different instances. To put it shortly—and apart from considerations of age of the parties, which was a matter of common sense—the law said that if either of the parties to a marriage was incapable of consummating that marriage, after reasonable efforts to effect a consummation, the other party had the right to apply for a decree of nullity. There must be incapacity before the decree could be granted; if one of the parties wrongfully refused intercourse, no decree would be made. The differences which arose were not in the law, but in its application. In these cases only two people really knew the facts; from what he had seen it was sometimes very difficult for a medical man to ascertain those facts. He instanced a case where a couple had been married for a considerable time, after which the man obtained evidence that his wife had gone away with another man, and had for two week-ends occupied the same room in a hotel with the latter. On that evidence he petitioned for a divorce; the wife countered with a claim for nullity, and the medical evidence was that she was virgo intacta. The wife obtained her decree and both parties subsequently married again; the man now had a large family. Another great difficulty concerned the parties themselves; both had to give evidence, and usually in those circumstances the woman had no real knowledge of what the act of intercourse was. The man was not infrequently equally ignorant. Both thought that they knew all about it, but, apart from the general superficial knowledge common to everyone, it was hard to know how far to believe their statements. One party might not turn up, or might decline to contest the case; then one wondered if the case were genuine. He believed, however, that very few cases were not genuine. There were few things which people, especially women, hated more than to be considered incapable of marriage; and in such cases they would fight hard. That feeling, which was nearly as strong in men also, was the greatest safeguard against fraudulent cases. He would hesitate to advise alteration of the law with regard to the inference of incapacity in cases of apparent wilful refusal, for the only effect would be to assist the obtaining of fraudulent divorce. Some cases from the ordinary human point of view gave the appearance of mere wilful refusal; he believed that in many cases the real fact was that the person was incapable, and that the refusal, apparently voluntary, was involuntary. With regard to the application of the law, he felt that very likely all that was wanted was education as to what was, in fact, a real inability to consummate a marriage.

Mr. NOEL MIDDLETON thought that in the old ecclesiastical court cases it was difficult to find instances where a decree of nullity was granted save when evidence was given of structural defect of some kind. But there was no doubt that the ecclesiastical law was sufficiently elastic to enable judges to move with the times. He believed with Mr. Bayford that it would be better for the community that the law be left as it was. It was dangerous to venture a definition as to what form of wilful wrongful refusal should be admitted as a reason for the granting of a decree of nullity. The most likely change which the legislature might make would be to admit wilful wrongful refusal as a ground for nullity; but one act of copulation would then be sufficient to enable one party to provide against the marriage being declared null and void, and little could be said in favour of such a change, for although one act might be consented to, all others might be refused. Any such change would, he thought, be fraught with great danger. The law was quite capable of advancing with the times and with the advancement of medical science. He held that in 999 cases out of 1000 the law was quite sufficient as it stood. With regard to the provision concerning incapacity, the court was on firm ground, and if properly instructed by the medical evidence could deal with widely differing cases. But beyond the rock of incapacity was a sea of difficulties, wherein it was impossible to reconcile the views of doctors and legal men. With regard to wilful wrongful refusal, he instanced a case where a boy and girl were married without apparently realising the meaning of marriage, and separated immediately afterwards, the girl going home and the boy back to school. The marriage was kept secret for a long period, until the young husband came to realise that he was grown up, and disclosed the ceremony. The girl's mother, not realising that the marriage was actually a marriage, forbade the girl to see her husband again. The man went abroad for some time, and on his return his wife wilfully refused to have anything to do with him. There was no medical evidence of any sort of incapacity or nervous trouble; and it might be considered a hardship that the man could not get a decree. It was a hard case, but hard cases made bad law, and had a decree been granted it would have helped to make bad law. With regard to Dr. Belfrage's suggestion that a committee be appointed to consider the state of the law, it would be valuable to have the medical aspect discussed, but if he were to give any evidence before that committee he would urge that they gave no sanction to any alteration of the law. He would, however, say to those medical men who gave evidence that the oftener they could impress the judge with the medical aspect of the case the better would be the law applied in that case.

Further Discussion.

Dr. GUY WOOD agreed with Dr. Belfrage to a great extent. The mental condition had to be considered in these cases, but doctors were questioned almost solely as to physical conditions. It was well that this point should be emphasised.

Mr. H. W. BARNARD agreed with Mr. Bayford and Mr. Middleton that any change in the law of nullity would be harmful to the community. He pointed out that any facility for divorce in such cases would present a loophole of escape for those who wished to

avoid a marriage which they had found distasteful. At present a nullity suit must not be prosecuted in collusion, and if that law were held to, it would be fatal to allow divorce in these cases.

Earl RUSSELL said that the law of nullity as a whole contained a great deal of humbug, much of which had, however, come to be valuable. Although the general principle of the law had not changed, its application was no longer limited to physical questions as it had been 200 years ago, when nerve storms and neuroses were not dealt with, or, at any rate, not admitted, in the courts. The lawyers present had all opposed a change in the law, but the courts did actually legislate by extending the law. Divorce on the grounds of wilful and persistent refusal might lend itself to collusion, but all such difficulties would be met if divorce after a period of desertion were adopted. He would mention one matter not entirely germane to the discussion—namely, the procedure in cases of suits for nullity of paupers. In these cases considerable charges were made by medical men, although legal services were rendered free. It would, he thought, be well if some authoritative medical body would consider the matter of these charges. As to whether some new statute should be made or whether the courts should be left to broaden the law to meet individual cases, he would point out that it was easy to legislate without a clear apprehension of what would flow from the legislation. Would medical men suggest what change might be made in the order to examine which they received from the court?

Dr. C. GRAHAM GRANT, speaking both as a lawyer and as a medical man, believed that marriage was a contract to which sex intercourse was vital, and if such intercourse was not carried out the contract should be set aside. He was convinced that when the law insisted that a contract be maintained between two parties who did not consent to it, then the law was bad.

Mr. NORBURY thought that in certain cases of wilful persistent refusal it would help if the medical man who had given evidence, and had heard the parties to the suit give evidence, were again called later and asked his opinion of the mental state of the persons concerned.

Dr. H. J. NORMAN felt that the discussion of the mental side of such cases would raise interesting points in the future. At present the views of the newer school of mental experts were in a state of flux. With regard to uncontrollable impulse, unless a definite mental trouble was present it was difficult to accept or support a plea on that ground. But a person might marry, never consummate the marriage, and break down mentally soon afterwards; he instanced a case of manic-depressive insanity where this happened, and emphasised the difficulty of such cases, in which the conditions of insanity might alternate with no intervals between them or might occur at prolonged intervals, the victim being completely sane between attacks.

Mr. G. C. TYNDALE said that some lawyers regarded with great uneasiness the present state of the law of nullity of marriage. Many people felt that the state of affairs in face of a wilful and wanton refusal was an abomination, the unfortunate petitioner having no release at all. He hoped the legislature would see to it that this old and genuine grievance was swept away.

Dr. BELFRAGE, replying, said that the most important thing was to get a definition of incapacity. He had not wished to urge an alteration of the law, and thought that such alteration would be very difficult. He would, however, suggest that the words "physical or nervous impediment" be included in the affidavit which a medical man was asked to supply to the court. The personal pride of the parties of which Mr. Bayford had spoken made the medical man's task no easier. His own feeling was that the judge, rather than counsel, required to be educated.

ROYAL SOCIETY OF MEDICINE.

COMBINED MEETING OF THE SECTIONS OF MEDICINE, NEUROLOGY, OPHTHALMOLOGY, AND OTOLOGY.

VERTIGO.

A MEETING of the combined sections was held on Feb. 26th to discuss the subject of Vertigo, Dr. ROBERT HUTCHISON, the President of the Section of Medicine, being in the chair.

The Standpoint of Medicine.

Sir HUMPHRY D. ROLLESTON opened from the standpoint of medicine. Accepting Mr. Sydney Scott's definition of vertigo as "a state of consciousness of the effect on motor centres of a want of harmony between afferent impressions," he said it could be held to include disturbances of the whole vestibular system, however caused, whether by organic lesions or by toxins acting directly on nervous tissues, or indirectly by inducing vascular spasm or dilatation. The afferent impressions, in the order of importance, were vestibular, ocular, kinæsthetic (muscular, articular, and visceral sense of movement). There must be reservations to any general rule. Gowers, who considered that 90 per cent. of cases of vertigo were aural in origin, referred, under the heading of "Pseud-aural Vertigo," to cases with slight evidence of labyrinthine disease, in which that authority supposed that a disturbance of function of the cortex set up by a slight peripheral derangement of the semicircular canals became gradually independent and purely central.

Diagnosis by Vestibular Tests.—Sir Humphry Rolleston said neuro-otology or analysis by the new vestibular tests enabled a diagnosis to be made of organic lesions of the vestibular apparatus, and in that way the points to be discussed by a physician could be narrowed down—as distinct from the specialist spheres of the otologist, the ophthalmologist, and the neurologist—to two chief categories: (1) What was the evidence that the action of toxins, transient vascular changes, or functional disturbances of the part of the cerebral cortex where the sensations concerned in equilibration normally met in harmony, might cause vertigo; (2) the ways in which general disease or visceral disorders affected the vestibular apparatus. Perhaps the vestibular tests could not be relied on to detect transient changes of the vestibular apparatus; hence in a case of vertigo in which, in the interval between attacks, the tests did not show abnormality, it might be impossible to determine that a passing functional disorder of the cerebral cortex was responsible, rather than one of other parts of the vestibular apparatus. Toxic, vascular, or functional disturbance at the cortical end of the vestibular system might occur, judging by epileptic auræ and borderland cases of epilepsy—viz., vertigo as an aura and the occurrence in an epileptic of vertigo without a fit. It would be interesting to hear if deaf-mutes with complete destruction of both labyrinths experienced vertigo when put under the influence of vertiginous drugs, such as quinine, alcohol, lead, and enterogenous poisons such as indol. A number of poisons due to defective metabolism were considered by many capable of causing vertigo; but at present one could not say where the transient disturbances causing vertigo occurred. Under the second heading, that of general disease, Sir Humphry Rolleston remarked that it had been said anaphylactic conditions might affect the semicircular canals. Some patients with hypersensitiveness, as shown by asthma and urticaria, had attacks of giddiness excited by taking certain articles of food, and the attacks ceased when those foods were no longer eaten. Parkes Weber thought it possible that angioneurotic manifestations in the labyrinth, by increasing the pressure of fluid in relation to the semicircular canals, might cause vertigo; and Vernet suggested that endocrine disorders might produce it by modifying the vasomotor conditions in the vestibular

labyrinth, and therefore advocated the oral administration of adrenalin. But knowledge on this was as yet uncertain.

Gastric Manifestations and Vertigo.—He said the gastric manifestations and vertigo were now widely regarded as concomitant effects of vestibular disturbance instead of standing in the relationship of cause and effect. Yet gastro-intestinal disturbance could conceivably be a primary cause of vertigo, either reflexly through the brain-stem, or by generating poisons which might act directly on the vestibular system. Sometimes vertigo was thought to be due to biliousness, and it might be that the hepatic insufficiency prevented the neutralisation of enterogenous poisons, such as indol. In two recent cases of headache and vertigo Holmes found an excess of uric acid in the blood and the symptoms disappeared when this excess was corrected.

Vertigo and Arterial Disease.—The association of arterial disease with vertigo could be explained in several ways. The high blood pressure, which so commonly preceded and caused arteriosclerosis, was associated with increased pressure of the cerebrospinal fluid and of the extra-labyrinthine fluid, and great variations might occur in both. And the vessels in this disease were more than normally prone to spasm and the latter had been stated to be a cause of vertigo. Attacks of vertigo might be due to transient cortical anæmia depending on vascular spasm. It was interesting to note the occurrence of vertigo in the Stokes-Adams syndrome, and its absence in simple heart-block. In cases of arteriosclerosis combined with renal disease vertigo could be explained in several ways. Embolism of the vessels of the labyrinth, such as might occur in malignant endocarditis, might so modify the conditions in the semicircular canals as to cause vertigo. Possibly the giddiness of caisson disease was due to embolism of bubbles of nitrogen in the vessels of the labyrinth, and the large arc of the cerebral cortex might be similarly affected. Laryngeal vertigo had been explained in various ways, and with regard to blood diseases, both anæmia and erythræmia might sometimes cause giddiness; the question was on what part of the apparatus the altered blood exerted its influence. In erythræmia, probably plethora would affect the vestibular labyrinth more readily than the central nervous system.

In conclusion Sir Humphry Rolleston referred to paralysing vertigo, described as occurring in small epidemics around Geneva in the eighties, by Gerlier. Since 1901 the disease had not been seen. It appeared in the summer and vanished with the onset of cold weather, and was confined to agricultural labourers or shepherds. It was considered to be due to stable infection. It appeared never to have been fatal.

The Neurological Aspect.

Dr. GORDON HOLMES discussed the subject of vertigo as arising from diseases of the central nervous system. He referred to the difficulty of ascertaining what was the exact condition to which the patient applied the term dizziness or giddiness. There was a tendency to regard the patient as stupid, but in any attack of vertigo there was always transient mental confusion and marked inattention. Another difficulty was to exclude all peripheral factors, especially lesions involving the semicircular canals and labyrinth, and producing vertigo either temporarily and directly or secondarily leading to an instability of the central nervous system or some portions of it. He set out the classification of vertigo which had been of practical use to him.

Classification of Vertigo.—The first class were the cases in which the vertigo arose from local lesions involving the central connexions of the vestibular nerve. The portions of the central nervous system which were only indirectly connected with the labyrinth, parts of the medulla, pons, cerebellum, and the mid-brain. Intra-medullary causes were probably less common. Vascular lesions of the cerebellum were not uncommon, and in these vertigo was frequent. He did not think pure cortical vascular lesions, such as small softenings on the surface of the cerebellum, often caused giddiness, but when the softenings extended to the central nuclei, particularly when they involved the peduncles, vertigo was very common. Tumours, especially of pons and cerebellum, were perhaps an even more common cause. And degenerative processes, affecting chiefly the cerebellum, and frequently the pons, might cause vertigo, but not so dramatically.

The second group of focal lesions to be considered were those in the fore-brain, especially in the cerebral cortex. He did not know of any unequivocal evidence that any form of disease of the basilar ganglia, or even the deep portions of the central white matter of the brain, caused vertigo in a direct way. But any lesion of the cerebral cortex that produced spasmodic phenomena could cause vertigo; tumours of the frontal lobe of the brain were a good example of this.

In his third class he placed vertigo, which was merely a symptom of another disease, occurring as an equivalent manifestation in epilepsy or migraine. Vertigo was not uncommon in epilepsy, first as a warning of the attack, and secondly replacing the attack. People who suffered from migraine seemed more liable to have vertigo, quite apart from their megrinous attacks.

His fourth class were subjects of hysteria. He asked whether vertigo was ever a hysterical manifestation. His own view was that vertigo was never due to hysteria, though the symptoms of the latter were so protean that the patient would frequently complain of what seemed to be vertiginous manifestations.

The Ophthalmic Standpoint.

Mr. J. HERBERT FISHER introduced the subject from the ophthalmological point of view, giving his own personal observations. He referred first to objective localisation or objective orientation. Disorder of this might lead to metamorphopsia, polyopia, and errors of judgment, but he did not think it ever caused true vertigo, though when other factors were present, it would add to the mental confusion. It had been said that unaccustomed visual sensations might, per se, cause vertigo, and he believed that unperceived ocular movements played the important part in causing the vertigo resulting from gazing at a waterfall. Patients often used the word giddiness in a sense which was far from scientific or accurate; but correction of astigmatism by oblique cylinders certainly disturbed ocular judgments, and refraction errors should not be ignored in dealing with cases of vertigo. The relative values of objective and subjective orientation was an interesting question. In a man with only one eye available, no sense of vertigo was experienced Abnormal impulses from disordered ocular muscles might reach Deiter's nucleus in the cerebellum, and in the latter might provide reflex irritation of the labyrinthine nerve centre, and thus a sensation of vertigo. This was at least worthy of consideration in regard to the vertigo of insular sclerosis when nystagmus was present. Vertigo was a frequent symptom in disseminated sclerosis. When ophthalmoplegia externa was also present, the resulting diplopia would add further to the confusion of the visual judgments. He gave a number of reasons for his belief that the sense of vision contributed to equilibrium only when it affected consciousness through the higher perception centres. He regarded equilibrium as a subconscious process maintained by tactile and muscular sense, and provided for, above all, through the semicircular canals, the vestibular nerve, and the cerebellar centres. To the sum total of muscular sense the muscles of the eyeball contributed their quota; disorder of the muscular and tactile elements of balance produced incoördination, which might suffice to cause stumbling movements, or loss of equilibrium sufficient to produce a fall without originating any perception of vertigo. The higher developed special

sense of vision could operate only as a higher mental perception. Normal visual impulses, normally projected on the sensorium, contributed to equilibrium, and might be able to control a vertigo generated by disorder of other mechanisms. Unaccustomed impulses generated by a disordered retina would produce no sense of vertigo if they were normally transmitted to and projected upon the sensorium, though they might disorder visual judgments.

The Otological Side.

MR. SYDNEY SCOTT, by means of an instructive series of slides, dealt with the otological side of the question. If a patient was able to hear the very low tones on the musical scale, the fenestra of the labyrinth could be adjudged intact. In general, inability to hear low tones indicated an interference with the ossicular apparatus of the middle ear, and when the lowest heard tones were quite high, there was present a more gross lesion than fixation of the ossicles. Two cases in which this was so were found to have auditory nerve tumours. When a patient subject to vertigo afterwards became deaf, he ceased to be giddy.

Conditions met with in Otology causing Vertigo.—With regard to the conditions met with in otological practice which set up vertigo, it was either an interference with the normal labyrinth or a destruction of the normal labyrinth. He showed slides of middle ear infections which had destroyed the membrana secondaria and set up a process of disintegration. Another class of causes interfering with the labyrinth were those in the region of the auditory nerve itself. He had seen over 40 cases of tumour in the lateral recesses which had affected the auditory nerve and caused marked deafness and vertigo; in some of these there had been vertigo without deafness, and in the latter the lesion had not been in the recess angle, but lower down in the nuclei in the medulla—i.e., the cochlea escaped and the vestibular nerve was involved. Concerning the effect of destruction of the labyrinth as a whole, he showed the photograph of a dog whose labyrinth was destroyed, to illustrate the characteristic stance due to the ablation, with displacement of the head and abduction and slight extension of the extremities. He proceeded to discuss, by the aid of a diagram, the mechanism of the vestibular reactions and tests, and the influence of various diseases, especially sinusitis, in causing vertigo. He concluded by drawing attention to the importance of making proper tests before arriving at conclusions as to the condition present.

Sir JAMES DUNDAS-GRANT said that one point was the difficulty of diagnosis in the cases which came suspected of being Ménière's disease, cardiac syncope, laryngeal syncope, petit mal. Small doses of quinine had an extraordinary action in checking, and almost stopping, the attacks of aural vertigo. If in a unilateral case the quinine did not diminish the vertigo, probably it was not a case of semicircular canal defect. He thought the quinine equalised the two labyrinths by its sedative action on the sound one. In the normal state the movement of the stapes and of the membrane of the round window acted as safety valves, and there might be a small vascular increase of pressure in the internal ear, but it did not cause disturbance because the two safety valves acted, but when they were fixed this action was lost. That, he thought, was the explanation of Mr. Sydney Scott's observation that one could often check the vertigo by compressing the carotid. In some of the worst cases the speaker had had to deal with, the cause had been cholesteatoma. With regard to the sympathetic, there had been experiments carried out recently on the action of the sympathetic nerve on the circulation by pressure in the labyrinth, and the consequent changes in the responsiveness of the labyrinth to the caloric tests. One German experimenter blocked up both the vertebral arteries just as they entered the skull, and also tied one carotid canal, so that the circle of Willis was supplied by only one carotid. The experimenter then tested the rapidity of response to the caloric test in the ear on the same side as the open carotid and observed the length of time needed to induce nystagmus. He then stimulated the sympathetic in the neck on that side, and it caused contraction of the blood-vessels, and a great deal longer was required to induce a response to the caloric test. The speaker's own observation was that the vertebral canals could be digitally compressed in the living subject by exerting the pressure in the sub-occipital triangles, at a point a little below the level of the mastoid. He tried the effect in a normal person of compressing the vertebrals in this way and found that it took distinctly longer to induce while this pressure was being maintained. He also referred to the fact that the late Sir Victor Horsley accepted Mills's localisation of a centre for the sense of equilibrium in the temporal lobe. Concussion, he considered, was a frequent cause of vertigo. Erichsen had pointed out that in "railway spine" following upon concussion, great relief was obtained by taking small doses of perchloride of mercury, so that patients would often return and ask for the medicine to be repeated. The speaker had found that drug had the same effect in the case of the vertigo caused by concussion.

Reviews and Notices of Books.

DIPHTHERIA: ITS BACTERIOLOGY, PATHOLOGY AND IMMUNOLOGY.

By FREDERICK W. ANDREWES, WILLIAM BULLOCH, S. R. DOUGLAS, GEORGES DREYER and A. D. GARDNER, PAUL FILDES, J. C. G. LEDINGHAM, C. G. L. WOLF. London: H.M. Stationery Office. 1923. Pp. 544. 12*s.* 6*d.*

THE latest monograph of the Medical Research Council, appropriately dedicated to Emile Roux, has been designed by its authors to cover the whole range of our scientific knowledge of diphtheria. It was a great task to attempt, and its execution is worthy of the Bacteriological Committee of the Council. The work as it stands is not a collection of independent chapters revised by a single editor, but all the seven bacteriologists take collective responsibility for the whole. No comprehensive work on the bacteriology of diphtheria has been issued for the last 15 years, and a glance at the bibliography in this monograph, which runs to more than 100 pages, shows how desirable it is to have the research of the last decade presented in a compact form. The modern story of diphtheria started with a brilliance which could hardly be maintained, for Behring's discovery of antitoxin—one of the greatest ever made in medicine—was fortunate in connexion with a disease in which antitoxic immunity counts as in no other.

The volume opens with a chapter on the history of diphtheria which recalls the antitoxin treatment by Geissler of the first child in v. Bergmann's clinic in Berlin on Christmas night, 1891, and Amand Ruffer's notable service in producing the antitoxin at the Lister Institute (then called the British Institute of Preventive Medicine) early in 1895. The second chapter deals at length with the bacterial genus Corynebacterium, a sub-group proposed by Lehmann and Neumann, accepted by the Society of American Bacteriologists, and now adopted by the Council. The term diphtheria bacillus is used throughout the monograph as synonymous with *Corynebacterium diphtheriæ*. The third chapter treats of the toxin of the diphtheria bacillus, its composition, preparation, and properties. Although a certain amount of experimental evidence suggests that the washed bodies of diphtheria bacilli exert a poisonous action distinct from that of the toxin proper, the authors hold, nevertheless, the belief to be justified that endotoxin does not play any significant rôle in the causation of symptoms. A very interesting chapter sets out the relation between diphtheria antitoxin and other antibodies, leading up to the conclusion that the antitoxic power of diphtheria antiserum is undeniably its most important property, the theory

that sera possessing full anti-bacterial powers (bacteriolysis, agglutination, &c.) would have a greater therapeutic efficacy remaining unproved. A full account is then given of the pathology of the disease, experimental and natural, the diphtheria bacillus producing general lesions mainly through the absorption of its toxin into the circulation. The gross anatomical lesions met with after death are very varied, and the report emphasises the difficulty of separating the action of the diphtheria bacillus from that of other micro-organisms which may be present. Under the heading of laboratory diagnosis, it is pointed out that the three racial sera prepared by A. S. G. Bell cover a considerable proportion of the diphtheria strains occurring in this country, and that where these sera are available an unequivocal positive result may be regarded as good confirmatory evidence of the nature of a doubtful bacillus.

A chapter on the serum treatment of diphtheria contains much information of value to the practitioner. Serum sickness is considered as an instance of allergy allied to, but not identical with, anaphylaxis, and the authors question whether true anaphylactic shock ever occurs in man. Nevertheless, intravenous reinjections should be reserved for the gravest and most urgent cases. The chapter on the incidence and spread of diphtheria includes a full description, with excellent coloured plates, of the Schick test and the subsequent toxin-antitoxin immunisation. The results obtained by W. H. Park, in the Brooklyn and Manhattan schools, are duly set out, and the conclusion reached that this mass effort reduced the number of cases of diphtheria to one-fourth—promising enough, when it is borne in mind that most of the immunisations were carried out by methods since superseded. An interesting section deals with the disputatious matter of the spread of diphtheria by animals; while scabs in cows are clearly not due to diphtheria, yet under some conditions, the authors admit, they may be a factor in its spread. Diphtheria may be superimposed on another infection owing to the habit of milkers spitting upon their hands. On the other hand, the circumstantial stories of cats suffering from typical diphtheria and transmitting it to children do not bear close serological examination. W. G. Savage found that the diphtheroids present in cats' throats produced no acid in broth.

In the chapter on prevention the question of the disinfection of carriers is set out with references. As far as available records go, the only form of treatment which appears to have decisive results is operative removal of infective tonsils and adenoids; since the carrier is himself immune to diphtheria, the harmless results of this operation are in keeping with expectation. A final chapter on diphtheroids is a remarkably readable presentation of a subject apt to be neglected except by the bacteriologist. No doubt, could once the systematic position of the non-virulent *C. diphtheriæ* be satisfactorily cleared up, the study of the parasitic diphtheroids of man and animals would become a botanical pursuit. At the present time this stage is far from being reached: even the morphology of individual strains of corynebacteria on the same medium, under the same conditions, is by no means constant.

As an exposition of the existing stage of knowledge in regard to diphtheria, this monograph will prove of great value to the medical profession and to scientific workers generally. Not the least, as the preface indicates, will it serve a purpose in showing how imperfect is our knowledge of diphtheria even at the present day, and in stimulating further research upon the problems as yet unsolved.

PSYCHOLOGY AND MORALS.

By J. A. HADFIELD, M.A. Oxon., M.B., Ch.B. Edin., Lecturer in Psychology, King's College, London. London: Methuen and Co. 1923. Pp. 186. 6*s*.

SEEKING to provide moralists with that knowledge of psychology without which moral teaching so often fails, Dr. Hadfield brings together some practical applications of modern theories and gives in rather dogmatic form, for which his preface frankly prepares us, his own interpretation of those theories. The simplicity thus attained is sometimes deceptive, as when he writes that it is unnecessary to deal with the "transference." Dr. Hadfield is fortunate if he has never met that hostile transference which nullifies all treatment until it is dealt with. There still appears to be a moral significance attached to the question of "free-will," and the author's efforts to reconcile it with psychic determinism are rather confusing. The merit of the book lies in showing that the recognition of impulses is necessary for a practical morality. This leads up to the psycho-analytical distinction between repression and control, processes often diametrically opposed and yet regarded as identical by those who think of psycho-analysis as teaching that we should allow a free rein to our instincts. As Dr. Hadfield says, "We cannot control our instincts as long as we repress them." The definition of "moral law" is difficult, and the author's confidence in its existence, "written on the tables of the heart," seems to rest, in spite of his protests to the contrary, upon what society approves or ostracises (p. 140). As a working principle this is excellent, but it scarcely possesses absolute validity. The book fulfils its main purpose, and should be of help to those who do not realise what psychology has to offer in the understanding of the nervous, the delinquent, and the many other misfits of modern life.

ANATOMY AND PHYSIOLOGY.

A Text-book for Schools of Nursing, Normal Schools, and Colleges. By JESSE FEIRING WILLIAMS, M.D., Professor of Physical Education, Teacher's College, Columbia University, New York. London and Philadelphia: W. B. Saunders Co., Ltd. 1923. Pp. 523. 15*s*.

PROBABLY no task with which an instructor in physiology is faced is so difficult as that of teaching beginners who have no knowledge of anatomy or biology, physics or chemistry. It is difficult to know where to begin. The author of this volume begins with the structure of the cell, the formation of the embryo, the simple tissues, and then leads on to the skeleton, muscles, and nervous system, before considering the circulation and other visceral systems. We do not much like this arrangement, logical though it may seem, but this is the only criticism we have to offer in reviewing this excellent little book. The illustrations are clear and up to date, the text is well written, and shows that the author has a real grasp of his subject, and the references to pathology and medicine make the book very valuable to the readers for whom it is intended. Directions for useful practical exercises, more for the guidance of the inexpert teacher than for the student perhaps, are included. If the book is used in conjunction with clear and simple lectures, students will get a very good idea of physiology from it.

ENCYCLOPÆDIA MEDICA.

Second edition. Vol. X., Obligate to Potash. General Editors: Vol. I.–VIII., J. W. BALLANTYNE, M.D., F.R.C.P.E. Vol. IX.–X., ALEXANDER GOODALL, M.D., F.R.C.P.E. Edinburgh: W. Green and Son. 1923. Pp. 672. 30*s*.

THE Encyclopædia Medica is so arranged that long articles are written on important subjects, while others of less moment are passed over in a few lines. The articles for the second edition have, in many cases, been entirely rewritten, while there is one new article. Prof. J. A. Milroy, discussing the physiology of the pancreas, gives a very good account of the recent work on the functions of the organ with especial relation to the internal secretion. The two kinds of cells in the islands of Langerhans are described, but an important point in the proof of the connexion of the cells with diabetes, supplied by Allen's partial pancreatectomy and overfeeding with sugar, has been omitted. Reference is made to the new work suggesting that the sugar present in the blood of

normal persons is in the γ form, whereas in the patient with diabetes mellitus this is not the case.

A clear account is given of the discovery and properties of insulin. It is a great advantage to have this article brought so thoroughly up to date. The section on the diseases of the pancreas, which does not include diabetes mellitus, is well written. The description of acute pancreatitis and its treatment should be especially useful. The new article on oxygen has been written by H. Whitridge Davis, and gives a clear account of the present standpoint of physiology. Seeing that pneumonia is also dealt with in this volume, it is an advantage to have the therapeutic uses of oxygen set out here. The point is made that oxygen should be given early and that the patient should be prevented from becoming cyanosed. The various methods of administration are described and are placed in the following order of election: (1) an oxygen chamber; (2) the Haldane mask; (3) various emergency methods. Oxygen chambers are rarely available. The Haldane apparatus has many advantages and is most useful for the mild cases, but often cannot be tolerated by the seriously ill patient. When this is so, a funnel must be used, and as Dr. Davis points out, this is a wasteful method. No note is taken in this section (although it is mentioned in that on the treatment of pneumonia) of the use of a nasal catheter, which can often be tolerated when the mask is rejected, and is an improvement on the funnel method. Pneumonia is dealt with fully, both from the bacteriological and the clinical side. A detailed account is given of the five types of pneumococci and the methods of distinguishing them. Statistics as to the value of the serum here given appear to indicate that however useful serum may be for the treatment of pneumonia in small animals like the mouse, it is of no great value for large ones like monkeys and man. The prophylactic use of vaccines in the prevention of pneumonia is discussed; the evidence seems to point to a reduced incidence and a diminution of the severity of the infection. This section on pneumonia is full of information, and should be of the utmost use to the practitioner faced with a severe case of the disease.

The editing has been well done, and the encyclopædia is of definite importance as a work of reference for medical men.

GERIATRICS.

A Treatise on the Prevention and Treatment of Diseases of Old Age and the Care of the Aged. Second edition, revised and enlarged. By MALFORD W. THEWLIS, M.D. With introductions by A. JACOBI, M.D., LL.D., and I. L. NASCHER, M.D. London: Henry Kimpton. 1924. Pp. 401. 21*s*.

IN the treatment of many complaints in the aged Dr. Thewlis urges especial attention to the condition of the kidneys. In the chapter on Senile Heart Disease, in that on Senile Rheumatism, and, again, in the discussion on the Complications of Senile Nephritis, the author emphasises the importance of nephritis. He states (p. 133) that "senile nephritis is one of the most treacherous conditions we are called upon to treat, because there are many complications that develop in organs which are distant from the kidneys, while the latter organs frequently display little evidence of disease. In other words, we may find serious symptoms, for example, in the brain, due to uræmia, yet the urinary picture may not be serious." Some cases of senile nephritis may be connected with old syphilis, and the author points out that the diagnosis in such cases is a most important matter with regard to the treatment to be adopted. In the chapter on Senile Bronchitis (p. 193) it is mentioned that a diet for nephritis will be satisfactory, even though the patient may not have nephritis. A microscopic examination of the urine should be made to discover whether the kidneys are diseased, since the latter is a common cause of senile bronchitis. Even of senile chorea, kidney disease is considered a possible cause!

In very rebellious cases of senile pruritus the author refers to good results obtained by the cautious use of radium or X rays. One chapter is devoted to the curability of some cases of hepatic cirrhosis and ascites. The author holds that some of the worst cases of "gin-drinker's liver" are seen in men who have been total abstainers all their lives. Ascites is more likely to be cured when the hepatic cirrhosis is hypertrophic. Atrophic hepatic cirrhosis is, of course, incurable, although regeneration of liver substance occurs. The use of alcohol is recommended in certain conditions. Special chapters added in the second edition are those on Electrotherapy and Opotherapy. One of the author's most characteristic chapters remains practically unaltered. It is entitled Keep Senile Cases out of Bed, and ends thus: "Getting out of bed spurs the aged sufferers to fight their battle more courageously. After all . . . the important thing is to encourage them and to give them plenty of attention. A talk about things that interest them sometimes has a better effect than medicines."

INFANTILE SURGERY.

Précis clinique et operatoire de chirurgie infantile. By L. OMBRÉDANNE, Surgeon to the Hospital for Sick Children, Paris. Paris: Masson et Cie. 1923. Pp. 1139.

The author of this excellent work points out in his preface that the surgeon who specialises in diseases of children must practise all the surgical specialties with the sole exception of ophthalmology. The book therefore covers a very large field extending from oto-rhino-laryngology to orthopædic surgery, leaving obvious and inevitable gaps in each specialty, but forming a very well-balanced whole. If the pathology is at times a little vague and the embryology occasionally unorthodox according to modern English views, the excellence of the clinical study of the cases and of the descriptions of operative procedure and after-care more than compensate for this. There is no bibliography; the author writes almost exclusively from a large personal experience which amply warrants his well-defined and dogmatic views. The book can be thoroughly recommended to those interested in children's surgery; they must be prepared to find divergences from English practice. The French is easy to read, and the copious illustrations are quite clear.

POISON MYSTERIES IN HISTORY, ROMANCE, AND CRIME.

By C. J. S. THOMPSON, M.B.E. London: The Scientific Press, Ltd. 1923. Pp. 412.

THE subject of poisons is a very interesting one, though it is a little difficult to see why poison mysteries are almost automatically called romantic. Crime by the agency of poisoning frequently presents absorbing legal and medical problems, but the central actions are almost invariably sordid and not romantic. The influence of poisoning on history is undoubted, but how great that influence has been we can never know, because it was almost a recognised political game to allege that the sudden disappearance of a monarch, an heir, or a minister, whose presence was inconvenient to any political party, had been removed by the instrumentality of poison at the instance of that party.

In the first part of Mr. Thompson's book there are collected notes at greater or less length upon most of the historic poisoning cases, and in this section there are also some distinctly interesting chapters on the curious methods employed by certain villains, and upon the love-philtres which have played a part in social life from the oldest days. The second part of the book tells the stories of 20 or 30 well-known murder cases: here the author is for the most part going over quite old ground, and a large number of the stories have been published with far greater detail. It is convenient, however, to medical men to have an outline of these stories bound up in one volume of so convenient a size, when further medico-legal details will be accessible where they are required.

Mr. Thompson's compilation is well written and readable from cover to cover. He has only designed to give outlines of his subjects, and these are clear and accurate.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

IX.—CERTIFICATION IN INSURANCE PRACTICE.

BY LEONARD SHOETEN SACK,
OF THE MIDDLE TEMPLE, BARRISTER-AT-LAW; JOINT AUTHOR OF "MEDICAL INSURANCE PRACTICE."

. . . . report me and my cause aright
To the unsatisfied.—*Hamlet*, Act v., Sc. 2.

THE evidence given at the recent capitation fee inquiry indicated that certification is the most criticised of the many duties required of the insurance practitioner. The profession contend that the certification rules are quite unnecessarily complicated and onerous. The case prepared by the Insurance Acts Committee went so far as to describe them as "oppressive and menacing," and expressed the view that they were not designed to secure to the insured person the sickness benefit properly due to him, but rather required the doctor to perform a service to the approved society under a threat of penalty. This expression of opinion is significant, because in no other respect did the profession complain that the panel doctor's duties are *unnecessarily* burdensome. The approved societies, on their side, allege that their funds suffer serious loss through loose and irregular certification.

Certification has necessarily a very real bearing on the whole financial structure of the national insurance scheme. Out of the total £22 million spent on benefits in England and Wales in 1922, more than £11½ million was for sickness and disablement benefit, and represented cash paid out to individual insured persons on the evidence of the doctor's certificate. This financial aspect was recognised by the Government in 1913 when a Departmental Committee was set up to report on the sickness benefit claims. The outcome was the appointment in 1920 of the regional medical officers, whose principal duty it was to act as referees to settle doubtful or disputed cases of incapacity. The number of references to these officers increases each year. The total references for England and Wales during the first three-quarters of 1921, 1922, and 1923 were 46,338, 81,200, and 107,242 respectively. In all, 288,728 cases had been referred up to September, 1923. In 52,558 of these—18 per cent.—the R.M.O. decided that the patient was capable of work, while in 41 per cent. of the cases the patient failed to attend for examination, usually no doubt, because he had meanwhile been certified as fit. While these figures do not necessarily connote widespread carelessness or wilful irregularity, they do suggest that health insurance certification is not yet fully satisfactory, and in particular that considerable difference of opinion exists as to the circumstances which justify the conclusion that a patient is incapable of work.

Doubtful Incapacity.

The certification of incapacity may obviously present considerable difficulties. A detailed discussion of those difficulties would involve medical considerations into which it would not be proper for a layman to enter. No precise definition of "incapable of work" has been officially issued, and it seems clear that no administrative decision or financial consideration should materially limit the professional judgment of the doctor. But cases arise where the question is not solely medical. Where the illness is one from which the patient is likely to recover within a reasonably short period, the only consideration is whether, for the time, he is capable of following his normal occupation or employment. Where, however, the illness is protracted or chronic, the question will, at some stage, arise as to whether the patient, although still incapable of following his previous occupation, is able to undertake some other remunerative work. The latter question, it may be argued, is one on which it is scarcely fair to expect the busy general practitioner to form a considered opinion, for it may involve inquiry into non-medical matters—e.g., the kind of remunerative occupation which is, in fact, available. It is true that the responsibility for deciding for how long cash benefits should, in such cases, continue rests with the approved society, but the doctor has still to decide when the incapacity certificates shall cease. Now these are typically cases which, it is suggested, should be referred to the R.M.O. It is one of the specific duties of that officer to decide cases of this kind, and there seems no reason why the practitioner should not free himself of unnecessary responsibility by taking advantage of the machinery which has been provided. At present, nearly all R.M.O. references are originated by approved societies and this tends to create an impression unfavourable to the doctor. It is sometimes feared that such references will involve loss of time to the busy doctor, in view of the requirement that he must attend at the examination if required to do so. In practice, however, the R.M.O. studies the convenience of the doctors and does not unnecessarily require his attendance. In any case, a reference by the doctor himself will ordinarily involve less annoyance and loss of time than will an ultimate reference by the approved society.

Obliging the Patient.

Most of the irregularities in certification can be traced to a few causes, which will here be briefly discussed. It is proposed to exclude from consideration cases of wilful misfeasance. A glance at the figures of certification complaints investigated by insurance committees suggests that such cases are relatively rare. The total number investigated by all committees in the British Isles from 1920 to 1923 was only 434, representing approximately one complaint for every 30,000 insured persons over a period of nearly four years; even in these cases the offence was sometimes trivial, and not infrequently the action of the doctor was upheld.

One fruitful source of trouble has been the attempt by the doctor to assist a patient in a technical difficulty. The certification rules definitely provide that:—

1. A First or Intermediate certificate need be issued only at the request of the patient.
2. A Final certificate, whether asked for or not, must be issued as soon as the patient is found to be fit to return to work; but it may not be issued if the patient has already returned to work.
3. All certificates must be given within 24 hours of the examination to which they relate.

Cases frequently arise where a patient neglects to ask for a first or intermediate certificate at the time of examination and subsequently (more than 24 hours later) applies for a certificate to produce to his society. Or a patient who has been receiving intermediate certificates may return to work without consulting his doctor and may subsequently ask for a final certificate. Hitherto the doctor has not, in such cases, been allowed to use one of the official forms, and he has had to choose between either writing out a special manuscript certificate or explanatory letter (probably resulting in further inquiries from the society) or refusing a certificate with possible loss of benefit to the patient. In these circumstances many doctors have felt themselves justified in using the regular form of certificate in "technical" breach of the regulations.

The voluntary certificate introduced last January meets these cases and, if properly used, should entirely remove this particular form of irregularity. The certificate states that the patient was examined on particular dates and was, in the doctor's opinion, incapable of work during a specified period. It is expressly intended for use where, through any action on the part of the insured person, the issue of one of the regular certificates is forbidden. It is issued at the doctor's discretion and the doctor is allowed to charge for its issue.

In future, therefore, a safe rule will be that in cases of doubt *due to the action of the patient* the voluntary certificate should be issued. Thus, the patient's interests are served by providing the society with the necessary evidence; the action taken on that evidence is, of course, a matter solely for the society. The voluntary certificate should not be used when the irregularity is due to the doctor's own action. For example, if the patient duly asks for a certificate at the time of examination, but the doctor, not having one at hand, neglects to send one within 24 hours, the regular form of certificate should be used, the actual dates of examination and of signing being entered.

Handy Certificate Books.

Complaints of irregular certification have, again, often arisen because the doctor had not the appropriate form to hand at the time of examination, and the writing of the certificate was afterwards delayed, perhaps through a succession of urgent calls. This has sometimes led to formal complaints of wilful retrospective certification. The difficulty is now largely removed by a more convenient printing and binding of the certificates. Excepting the voluntary and death certificates, which are printed separately, there are now only two forms; on one is printed the ordinary first, intermediate, and final certificates, while the other contains the special intermediate and convalescent certificates. Moreover, all the certificates, with the sole exception of the voluntary certificate, can be obtained bound in one book in suitable proportions; this book includes even the special notice to be given when intentionally vague certificates are issued. The doctor can, therefore, now conveniently carry a selection of every form of certificate required. Although the ordinary and special certificates are also issued separately in two books, the possession of a composite book by every doctor should prove of considerable convenience, particularly as an addition to his emergency kit.

Pressure by Societies.

There is ground for legitimate complaint that while the approved societies actively criticise irregular certification, they not infrequently, either directly or indirectly, themselves bring pressure to bear on the doctor to vary his normal certification practice. Sometimes the patient will press for a certificate which the doctor considers not to be regular, urging that it is being demanded by the society; sometimes the society's agent may press for certificates to be given on special days to accord with the society's paying-out time.

Coöperation between the doctor and the society is obviously desirable where it can be attained with due regard to the doctor's work and to the patient's interests. The sole discretion as to the withholding of a certificate or as to the date of a patient's examination rests, however, with the doctor, and it is believed that there would be a considerable improvement in the whole system of certification if the doctors more resolutely refused to issue certificates in circumstances of doubt until the doubtful point had been decided by the competent authority. The complaints so querulously voiced about certification irregularities on the part of doctors seem often to overlook the difficult position in which the doctor may be placed through irregularities on the part of the patient. It rests, however, largely with the doctors themselves to encourage a stricter observance of the regulations by the insured persons. The regional medical officers, the insurance committees, and the health insurance inspectors are the authorities available for deciding cases of doubt, and the maximum use should be made of their services. The patient who, in the doctor's opinion, improperly presses for a certificate should be referred for advice to the local inspector; while the doctor should seek the guidance of the insurance committee.

Diagnosis.

While societies have complained that the incapacitating cause is often not sufficiently indicated on the certificates, the profession have resented inquiry by societies into the adequacy of diagnosis. The certification rules, as the reader knows, provide that the incapacitating cause shall be stated as concisely as the doctor's knowledge of the patient's condition permits. On this point only two observations can here be made. Many societies have now formulated schemes for additional benefits, and those schemes sometimes provide for defraying the cost of certain special forms of treatment, which do not fall within the scope of medical benefit. It is, therefore, clearly to the patient's interest that the incapacitating illness should be shown with sufficient clearness to enable the society to consider whether the member should be assisted in obtaining special treatment. Further, now that the composite certificate books include the special notice to be given to societies when intentionally vague certificates are issued, the plea that the special form was not available can offer no excuse for the practice of "covering up" the real incapacitating cause by indicating some resulting condition—e.g., debility—just sufficiently to avoid "vagueness."

THE COÖRDINATION OF INTERNATIONAL RED CROSS ACTIVITIES.

IT will be remembered that the Eleventh International Red Cross Conference, held at Geneva in August, 1923, decided to appoint a commission to consider the international organisation of the Red Cross, and to submit a report on the subject, together with a draft statute, to the national Red Cross Societies. A conference composed of delegates to these societies was subsequently to be summoned to decide on the question of organisation. The difficulties to be solved arose from the existence side by side of two organisations, the International Red Cross Committee, formed in 1863, with its headquarters at Geneva, and the League of Red Cross Societies, formed in 1919, and established at Paris. These two organisations vainly endeavoured to arrive at an agreement; the matter was therefore placed before the conference which decided to make an attempt to deal with the difficulty by referring the question to the national societies. The commission of inquiry, formed in accordance with this decision, was composed of 15 members; 13 represented the national societies, whilst the remaining two represented the International Red Cross Committee and the League of Red Cross Societies.

The commission met for the first time at Brussels in November, 1923, when a general discussion took place. It appeared that the majority of the members were in favour of a solution whereby the harmonious working of the International Red Cross should be ensured by means of the practical coördination of its various services—a solution equally removed from the present overlapping existing between the International Red Cross Committee and the League of Red Cross Societies, and from the complete fusion of the two organisations. Ultimately the commission appointed a subcommittee composed of six of its members to prepare a draft statute for the International Red Cross, to be submitted to the commission at its next plenary meeting. This draft statute was prepared, and provided for the formation of a federation comprising both the national societies and the International Red Cross committee; it did not represent the unanimous opinion of the subcommittee, a counter-proposal being submitted by one of its members to the effect that all the international activities of the Red Cross should be in the hands of a single organisation, which should be a federation of the national societies, but not including the International Red Cross committee. The report of the subcommittee was placed on the agenda of the second meeting of the plenary commission, held in Paris at the end of January. At this meeting the efforts made to persuade the members unanimously to accept a compromise were unsuccessful. In these circumstances a vote was taken, the result of which was that the subcommittee's plan was adopted.

The commission will now submit to the national societies a report upon its work and the text of the draft statute adopted by a majority of its members, together with the counter-proposal and other suggestions submitted to it. Upon receipt of the remarks of the various societies in regard to these documents—which remarks should reach the secretariat of the commission before May 20th—the commission will once more meet for the preparation of its final report to the conference, with which the decision rests and which, according to a recommendation of the commission, should assemble in July next.

THE LANCET.

LONDON: SATURDAY, MARCH 1, 1924.

THE INCIDENCE OF RHEUMATIC DISEASES.[1]

A CONSIDERED study of the incidence of rheumatic diseases, founded upon records made by certain practitioners during the course of their practice among insured patients and collated by a committee of the medical staff of the Ministry of Health, has just been issued. It is the result of the first general and organised effort of insurance practitioners to undertake a group inquiry. If its importance on this ground receives less immediate recognition than it should, it will be because the matter, admirably presented, is of such absorbing interest as to exclude attention from the mechanism of its collection. The establishment of a uniform nomenclature, classification, and method of keeping records is the first requisite if any inquiry on rheumatic disease is to be kept within practical bounds, and the fact that so many groups of diseases are loosely packed together under the common label of rheumatism must have made this a formidable task. None of the existing systems of classification appeared to the committee or those who provided the records to be quite suitable, and quotations from the conflicting views on nomenclature of recognised authorities show that certain differences (such as on the need for distinction between osteo- and rheumatoid arthritis) are fundamental. Eventually, for the purpose of this inquiry, it was decided to classify into three main groups: (A) Acute rheumatism (rheumatic fever), together with subacute rheumatism; (B) non-articular manifestations of so-called "rheumatism" (muscular rheumatism, fibrositis, &c.); (C) diseases characterised by chronic joint change. These three groups were subdivided into nine categories, set out below, and the inquiry form on which observers were asked to record their findings contains also, for the less well-defined diseases, a note of the chief distinguishing signs and symptoms, so that the possibility of gross error in filling them up is practically excluded.

The inquiry had the great advantage, for statistical purposes, that the population at risk is known with reasonable accuracy, for the samples, taken from all parts of the country, may be regarded as typical anyhow of its insured population. The total number of rheumatic cases recorded was 2510 (1771 males and 739 females), which amounts to 27·6 per 1000 of the total population (approximately 91,000) under review. For every 1000 insured persons, each sex being considered separately, the incidence of diseases was approximately as follows: Group A, Rheumatic fever, M. 1, F. 2; subacute rheumatism, M. 3, F. 3. Group B, Muscular rheumatism, M. 6, F. 7; lumbago, M. 10, F. 3; sciatica or brachial neuritis, M. 3, F. 1. Group C, Rheumatoid arthritis (including infective peri-arthritis), M. 1, F. 3; osteo-arthritis, M. 3, F. 2; gout, M. 3, F. less than 0·1; unclassifiable chronic joint change, M. 1, F. less than 1. These figures must be considered in relation to the attack-rates for the various age-groups if their full significance is to be appreciated, and illustrative tables are furnished; it must be remembered that insured females have a much younger age-distribution than insured males. But the predominance of gout, and especially of lumbago, among males and the higher incidence of rheumatoid arthritis in females may well form the starting-point of further inquiries designed to throw light upon causation. The total length of sick absence attributable to rheumatic diseases amounts in males to one-sixth of the total sick absence due to all diseases, and in females to one-seventh. Joint diseases account for more than half of these enforced holidays, while it is noted that the comparatively small amount of sick absence shown as due to acute and subacute rheumatism constitutes only a fraction of the real amount of disability for which these varieties of rheumatism are ultimately responsible; for in this inquiry the sickness due to valvular disease of the heart unaccompanied during the year of record by rheumatic symptoms is not taken into account. The estimation of the financial loss involved is even more impressive than the attack-rates. If the sample of the general insured population is a fair one—and there is no reason to doubt this—it would seem that more than one-seventh of the total sick benefit, or over £1,800,000, is paid to, and 3,141,000 weeks of work are lost annually by insured workers on account of rheumatic diseases, excluding benefit paid or work lost on account of organic disease of the heart. This sum of wasted time and money, the proximate causes of which are further subdivided in the report, is in itself sufficient ground for the vigorous prosecution of research into causation and treatment urged by Sir GEORGE NEWMAN in his introduction to the report. It could not be expected that from this preliminary inquiry much of practical import in either of these directions would emerge, but even here certain indications, divided with nice precision into ascertained facts and impressions, are recognised. It is a fact, for example, that of patients with acute rheumatism nearly 50 per cent. had enlarged or septic tonsils and that only 2 per cent. had had their tonsils removed; it is an impression, derived from scrutiny of the records of the various forms of fibrositis, of the non-articular rheumatic manifestations, and of the chronic joint diseases, that dental sepsis may be a factor in ætiology.

As to future lines of research, sufficient geographical and occupational variations in the incidence of rheumatic diseases have come out of this inquiry to merit further investigation. Local variations in incidence of gout are especially noteworthy. As to preventive treatment, in the prophylaxis of valvular involvement the importance of arrangements for long rest during convalescence, so often emphasised in our columns, is brought out, and the traditional association of all varieties of rheumatism with damp houses is regarded as well founded; while the reduction in the incidence of acute rheumatism in this country and in America is attributed to the increased attention paid to tonsillar sepsis in school-children. Treatment, on the other hand—though Sir GEORGE NEWMAN believes that it is now beginning to enter upon a more hopeful phase—is admittedly unsatisfactory, especially in the chronic diseases. The establishment of arthritic hospitals or special clinics where treatment could be studied and the newer methods for the alleviation of symptoms tried out, is recommended. This recommendation will be endorsed by practitioners for two reasons. Not only would the concentration of patients suffering from rheumatic arthritis in the properly equipped institu-

[1] Reports on Public Health and Medical Subjects, No. 23, The Incidence of Rheumatic Diseases. H.M. Stationery Office. 1924. 2*s.* 6*d.*

tion have immense possibilities from the aspect of research, but such institutions would help to solve the problem of finding a place where these unfortnuate sufferers can be cared for.

There are many more points in this comprehensive survey of exceptional interest, and to these we shall have occasion to return. The report is a remarkable production and should silence for ever those who judge from the reluctance of the practitioner to fill up forms which he considers unnecessary his unwillingness to coöperate in a well-planned inquiry of limited scope.

BAYER "205."

EX AFRICA semper aliquid novi. There is something particularly stimulating in the discovery of a new drug and in the record of its success in such a particularly intractable and devastating disease as trypanosomiasis. It is therefore not unnatural that recent accounts of the therapeutic and prophylactic action of Bayer "205" in men, and to a certain extent in animals, has given rise to the hope of a brighter future for the Dark Continent. Were the great waterways of the Niger, the Congo, and the Zambesi free from this scourge, were life made possible for beasts of burden and pastures habitable for cattle, Africa might one day become the richest continent in the world. In his paper to the Royal Society of Tropical Medicine and Hygiene on Feb. 21st,[1] Prof. F. K. KLEINE gave a lucid and critical account of the action of Bayer "205" in Central Africa. Prof. KLEINE is one who believes little in speculations, but only in the results of well-planned experiments; he therefore deprecates, quite rightly, the idea that Bayer "205" is infallible for every form of trypanosomiasis. The methodical manner in which the therapeutic effects of this drug have been tested, first in animals, then in man, under his direction call for special praise even though Prof. KLEINE'S scientific reputation is firmly established.

In the discussion which followed Prof. KLEINE'S paper it became evident that the time for a systematic inquiry into many aspects of human trypanosomiasis has now arrived. As Prof. WARRINGTON YORKE pointed out, Great Britain, which has such large interests in Africa, has a natural responsibility to carry on the researches initiated by Prof. KLEINE on the Congo and in Northern Rhodesia; this should entail an accurate record over a number of years of the cases so far treated to ascertain the permanency of the cure. According to YORKE, the actual death-rate from human trypanosomiasis under natural conditions is unknown; there are areas in Southern Nigeria, for instance, where the trypanosome has become so attenuated as to be no longer pathogenic, while in other districts, as formerly in Uganda, the disease spreads like wildfire and causes a very high mortality. The factors which underlie these ascertained facts is unknown. The vexed question as to possibility of mechanical conveyance of trypanosomes by tsetse-flies, which YORKE and LYNDHURST DUKE believe to be possible—a view KLEINE vigorously opposes—should admit of an early solution. It may be necessary to study more minutely the life-cycle of the trypanosome in the peripheral blood, already outlined by Miss MURIEL ROBERTSON, for it is conceivable that in certain stages the organism becomes more vulnerable to the action of the drug. There is still much more to be learned about the dosage of Bayer "205," the reason of its action upon some pathogenic trypanosomes and inertness towards others—*Trypanosoma evansi*, for example—as well as of its mysterious attenuation of the virulence of *T. brucei* in cattle.

In animals repeatedly injected with Bayer "205" the trypanosomes soon develop a "fastness" towards this drug, and the same appears to take place with equal rapidity in man. In view of this fact the amount and spacing of the dosage becomes extremely important; KLEINE therefore suggests 2 g. as the initial dose given by the intravenous route and followed subsequently by three separate gramme doses at weekly intervals. Should, however, the trypanosomes return to the blood-stream in spite of this dosage they are then more susceptible to the action of some metallic drug, such as antimony tartrate or tryparsamide; the latter, according to Miss LOUISE PEARCE, of the Rockefeller Institute, has marked therapeutic properties, so that it is not improbable that by a combination or alternation of these drugs ultimate success in resistant cases may be achieved. Such an inquiry as we have suggested should envisage in its scope a comparative trial under similar conditions on an extended scale of these recent advances in the therapeutics of trypanosomiasis, and we would recommend such an investigation to the League of Nations so as to invest it with an international character. Certainly it is a subject of great economic importance; if mainly to the British Empire, it also concerns France and Belgium and, to a lesser extent, Portugal and Spain. Little information has been disclosed so far on the chemical composition or formula of "205." It is understood to be a complex organic aniline body, of which the nucleus is trypan-blue. We hope that in their own interests, as well as for the benefit of science, the manufacturers will soon be in a position to supply more detailed information on this point.

[1] See THE LANCET, Feb. 23rd, 1924, p. 384.

INSURANCE DENTAL BENEFIT.

THE position of "dental benefit" under the National Health Insurance Acts is not at present clearly understood either by the general public or by those members of approved societies who are entitled to participate in it. Dental benefit may be described as a statutory benefit, but it is not, like medical benefit, one to which every insured person is entitled. The only reference to dental treatment in the Act of 1911 is in Part II. of the Fourth Schedule, under "additional benefit," where of 14 specified benefits which might under certain circumstances become available to members of approved societies, No. 2 on the list provides for "the payment of the whole or any part of dental treatment." That any tangible gain would result from this provision was a contingency which few professional men in 1911 regarded as of any practical interest. Happily those members of the British Dental Association who saw the possibilities ahead managed by dint of perseverance to obtain in 1913 general approval by the dental profession of a scheme whereby dental treatment might be made available to the industrial classes on a uniform scale throughout the country. The scheme, in brief, provided for those persons coming under the wage-limit of the Insurance Act all the ordinary operations in dental surgery at agreed scales of fees by registered dentists grouped in voluntary panels. These panels were intended to cover the areas of counties, with subdivisions, where necessary, into district panels, and provision was also made for the formation of central committees in England, Scotland, and Ireland, which would coördinate and regulate the work of the local panels and conduct negotiations on behalf of the panels with Government departments or other bodies concerned. Although designed in anticipation of the valuation of the funds of approved societies in 1915,

the scheme was meant to be put in operation prior to that valuation and, in fact, public dental services were instituted in many parts of the country,[1] as, for example, in Bournemouth, Bristol, Brighton, Bedford, Birmingham, and Glasgow. The dentists joining the panel usually formed themselves into limited liability companies to facilitate administration. The war, unfortunately, interfered with the success of this effort—no profession having been more depleted by service with the forces than the dental profession—and in addition, the state of the law at that time permitted unregistered persons, either singly or in combination, to describe and advertise themselves as "Public Dental Services." Thus, an organisation voluntarily established by the profession, which promised to be of great benefit to the health of the community, fell largely into disuse.

The ultimate effect of the experience of the war on the attitude of the authorities and of the public generally towards dental service as an element in public health is well known. It produced first the Departmental Committee on the Dentists Act, 1878, appointed "to enquire into the extent and gravity of the evils of dental practice by persons not qualified under the Dentists Act." This Committee reported in 1919, and following upon that report the Dentists Act of 1921 was passed. When, therefore, the long-delayed valuations were at last completed, showing the existence of surplus funds in the hands of certain approved societies, dental treatment was offered by many of these societies as additional benefit to their members, and of all these benefits it has become that most in demand. In one society, for example, claims for dental treatment to the amount of £1500 per week are being passed. The number of approved societies and branches of these societies which include dental treatment among the additional benefits offered to their members is over 500, involving a membership of about 7 millions. Thus, as has been said, not all insured persons are entitled to the benefit, nor even all of the 7 millions stated, for of the members of the fortunate societies only those who have been continuously insured from a date not later than Dec. 31st, 1918, could claim the additional benefit resulting from the first valuation. The second valuation is expected to widen the possibilities, not only by the release of further surplus funds, but also by bringing into benefit those members of the societies who have qualified for benefit since the first valuation. In response to the demand thus arising, the scheme for industrial dental service already outlined was revived. The British Dental Association undertook the trouble and expense of putting it before all registered dentists by arranging meetings in all its branch areas over the country. In all these areas, 15 in number, public dental services were formed, and dental treatment at an agreed scale of fees on certain conditions was made available for the members of approved societies in every part of the country. Having organised the service, the Association by its constitution was unable to carry it on. The service was open to all registered dentists, and many of these dentists, particularly those registered by virtue of Section 3 of the Dentists Act, 1921, were not members of the Association. Therefore the Public Dental Service Association of Great Britain, Limited, was formed, of which all the local services already established became branches. This Association was registered as a limited liability company on Dec. 27th, 1922. Its registered office is in London and it controls the service through a central committee of representatives of all the branches. All registered dentists are eligible for membership. Its membership at present is over 5000 and is extending, as it is in the interests of all registered dentists who desire to participate in public work to join an association which can represent them and protect their interests when questions as to the interpretation of the conditions of service arise.

The whole question of public dental service is at present in an interesting stage. Dental treatment for members of approved societies—chiefly at present given as additional benefit—does not seem to fall under the description as "of the nature of medical benefit" and therefore does not come under the control of the insurance committees, but is administered by the approved societies concerned, subject to approval by the Insurance Department of the Ministry of Health of schemes drawn up by the societies. Questions as to conditions of service and remuneration had, therefore, in the circumstances, to be settled directly between the dentists and the approved societies, and there is at present in existence a joint committee of representatives of dentists and of approved societies for this purpose. The present arrangements must be regarded as temporary and in a measure experimental. The benefit of dental treatment is only reaching a comparatively small number of the persons requiring it, while, notwithstanding the publicity given to the matter, very many of those entitled to the benefit are ignorant of its existence or of the means of claiming it. Dr. H. S. Beadles has forcibly pointed out (see p. 475) how unfairly this uneven distribution of benefits works out in practice; territorial administration alone could give the desired relief. With dental benefit as it exists at present some beneficial results are apparent in a lessening of claims for sickness benefit in those ailments which can be most certainly associated with dental defects. It is certain that the methods by which the treatment is given are susceptible of great improvement, and would require serious modification in any scheme of permanent dental benefit which may be contemplated in the future. Above all, it is desirable that conservative and preventive treatment should be encouraged. Nothing could be more disastrous to the interests of public health than to dignify with the name of "benefit," and to encourage and perpetuate by the expenditure of public funds, the extraction of teeth and the insertion of artificial dentures which has been the chief dental treatment sought by the industrial classes hitherto. It is to be presumed that if and when that permanent dental benefit be instituted, as it seems destined to be, the methods applicable to medical benefit will be found applicable to the benefit given by the allied profession of dentistry. Presumably the promised Royal Commission on the National Health Insurance Acts will have this matter under consideration and the experience of the present service will be utilised by all parties concerned and not least by the dentists in suggesting methods for rendering available to the industrial classes in the future such a dental service as shall produce lasting and beneficial effect on the health of the community.

MEDICINE AND THE EMPIRE EXHIBITION.

IN connexion with the British Empire Exhibition a committee of medical men has been formed with the object of welcoming their colleagues from the Dominions and Colonies visiting the metropolis. The Committee comprises the President of the Royal College of Physicians of London, the Vice-Chancellor of the University of London, and the Presidents of the Royal Society of Medicine, of the Medical Society of London, and of the various metropolitan medical societies. One of the first duties of this Committee will be to form an executive body and undertake the organisation of hospitality to be extended to medical practitioners from overseas. For this purpose it is desired to ascertain beforehand, as far as possible, the names of the intending visitors and the periods of their visits, and it is requested that intending visitors will communicate without delay to the hon. secretaries of the Hospitality Committee, Mr. Mortimer Woolf and Mr. E. T. C. Milligan, at 1, Wimpole-street, London, W. 1. A preliminary meeting of the Committee has been held, and the personnel will be duly announced. The Royal Society of Medicine, acting in coujunction with this Committee, will welcome all duly accredited members of the medical profession during their stay in the home country.

Annotations.

"Ne quid nimis."

AN INVESTIGATION OF CHILD LIFE.[1]

THE effect of maternal social conditions and of nutrition upon the weight and stature of the infant has been made the subject of an interesting and careful report to the Medical Research Council by Miss Bruce Murray. The general answer to the question generally proposed by the subject of the report is in the negative—the effect is small; but the findings are of high scientific value because the nature of the research and the material for investigation were both carefully defined. Only selected mothers and only certain infants were taken into consideration, and it is obvious that if the symbiosis thus arrived at displays little of the sad phenomena associated with the bad development of infancy that we see around us, it is because in the process of selecting the material the sinister factors have been eliminated. We are thus definitely assisted as to directions where remedies can be supplied.

Miss Bruce Murray, an Associate of the Institute of Hospital Almoners, has thoroughly investigated the records available at St. Thomas's Hospital and the General Lying-in Hospital, Lambeth, where notes have been kept of the social as well as the medical aspects of all the cases admitted for the last nine consecutive years, covering therefore pre-war, war, and post-war conditions. On the medical side full details were available concerning mother and child in the case-statements, including accurate records of measurements, while in the lady almoner's departments was found the information needed for correlation of the wages and social conditions of the family. These departments could place before the investigator case-papers showing every point in each patient's social circumstances throughout the last months of pregnancy and for some considerable time after confinement. Miss Murray, having digested the records, made house-to-house visits to many of the families, and then selected her material, so that the terms of reference in her report should be clear-cut. To avoid confusing the issue by such influences as size of the family or place of the infant in the family, only primiparæ are dealt with, and in this way the part played by maternal fatigue is omitted. All cases where maternal illness might affect the child, such as renal and cardiac disease, and, of course, syphilis and phthisis, have been excluded, as well as cases attended by the difficulties or abnormalities of labour complicated by eclampsia or ante-partum hæmorrhage. In this way a coördination of records has been possible which should definitely point to the effect which varying social and financial conditions have on birth-weight and birth-length. The classification of cases was then made, not according to social class, standard of living, total resources, or amount of rent paid, but the position of each case was decided by its expenditure, an average of net incomes being struck, when the cases were arranged in two classes above or below this average. The factors popularly supposed to affect birth-weight and birth-length were then found to exercise little influence. All mothers suffering from serious illness being excluded, it was seen that neither age nor stature in the mother played any determining part, while investigation of the season of birth pointed, though not definitely, to March as being a bad month of arrival. Comparison with material investigated at maternity homes presented difficulties, as, for example, the average age of the mothers was higher here than in the hospitals, nor was it possible to be certain that only infants would be included whose mothers were within the selected class of health. The general conclusion is arrived at that poverty, lack of proper nourishment, and generally unfavourable social circumstances during pregnancy do not produce the commonly accepted differences in the offsprings. As regards the hospital cases the averages for the war years showed no significant falling off in weight, though the average net income during two of those years was particularly low.

What is the positive finding of this interesting report? It is, as Dr. J. S. Fairbairn points out in his preface, quoting words also quoted by Miss Bruce Murray—"The fœtus lives like a true parasite, regardless of the expense to the mother." The whole document is a demand for the care of the parturient.

THE LEPTOSPIRA ICTERO-HÆMORRHAGIÆ IN RATS.

THE recent epidemic of spirochætal jaundice occurring among miners in East Lothian has been the subject of investigation by the Scottish Board of Health, with the result that the disease is now locally notifiable. The question of the disease falling under the Workmen's Compensation Act was brought up in the House of Commons this week, but at present sufficient data as to its ætiology are not available to justify its inclusion under the terms of the Act. Epidemic infectious jaundice, an acute non-contagious disease characterised by fever, jaundice, hæmorrhages, and nephritis, occurring in epidemics or in localised groups, was first fully described by Weil in 1886, and in 1914 Inada and Ito discovered the causal organism to be *Leptospira* (=*Spirochæta*) *ictero-hæmorrhagiæ* This virus, according to Noguchi,[1] is a very minute organism, capable of passing through Berkefeld filters. Outside the human body it was first found to exist as a harmless parasite in the kidneys of field-mice by Miayima, and shortly afterwards, in 1916, Ido, Oki, Ito, and others discovered its presence in the rat, and their researches showed that the rat was responsible for human infection. The spirochæte is excreted in the rat's urine, and it is conceivable therefore that infection occurs as the result of exposure of the human being to soil on which the urine of these animals has been freshly deposited, or through the ingestion of food which has been left unprotected from such sources of infection. Animal experiments have shown that the organism is capable of penetrating the intact skin as well as the mucous membranes of the alimentary tract.[2]

In its geographical distribution the disease occurs in its most severe form in Japan, where it has been most widely investigated, but it occurs also in Central Europe, Southern France and Spain, and in the United States. In the recent war it made its appearance among the troops in the trenches on the various fronts; in October, 1916, Drs. L. Martin and A. Petit published an interesting note in the *Bulletin de l'Académie de Médecine* on the existence of the disease in the French Army, and in 1917 Drs. A. Stokes and J. A. Ryle contributed a full account of the infection in the British Army in Flanders to THE LANCET.[3] A case occurring in London was fully investigated and reported by Dr. P. Manson-Bahr[4] in 1922. Investigations carried out in all areas where the disease has manifested itself have established the common rat, *Mus decumanus*, as the chief carrier of infection. In the East Lothian outbreak live wild rats were obtained from the centre of infection, two from one of the coal-mines, and one from the surface at about a quarter of a mile from the pits, and examined by Dr. G. Buchanan.[5] Motile and characteristic leptospiral forms were found by dark-ground examination in emulsions made from the kidneys of the surface rat and one of the pit rats. No spirochætes were found in other organs, the urine,

or the blood. The blood was infected by *Trypanosoma lewisi*. The rats were well nourished and showed no sign of disease.

It is of interest to compare these results with the recent investigations of Profs. W. Schuffner and W. A. Kuenen into the condition of rats in Holland.[6] They examined, by dark-ground illumination, the kidney scrapings of a large number of rats in Amsterdam. Out of a total of 209 of the species *Mus decumanus*, 27 per cent. were found to be infected; of 29 of the species *Mus rattus*, only one contained the organism. They concluded that in comparison with other towns the percentage of infected rats in Amsterdam was fairly high, about equal to that of London (Stevenson). They also examined for *Trypanosoma lewisi* and found that 14 per cent. of the *Mus decumanus* and 7 per cent. of the *Mus rattus* were infected. In the case of old rats, the spirochætes were found in a much greater proportion of cases than among young rats (45 per cent. against 2·5 per cent.); the relative incidence of trypanosomes was 11 per cent. against 16 per cent. in young rats. Like Stevenson, they found the spirochætes in the kidney collected in foci, not in the kidney-substance but in the tubes. In the case of the rat the investigators hold that the infection gradually increases in virulence. Cases of Weil's disease in Holland are rare and the high infection percentage among rats came as a surprise to the investigators.

SECONDARY INFECTIONS IN PULMONARY TUBERCULOSIS.

Prof. Paul Courmont and Dr. Boissel,[7] of Lyons, state that until recently it was generally held that the tuberculous lung was almost always invaded at a certain stage of the disease by other organisms than the tubercle bacillus, and particularly by pyogenic germs. A considerable proportion of the patients' symptoms were attributed to secondary infection, especially the hectic fever and the aggravation of the general condition. The therapeutical consequences of this view were that mixed vaccines consisting of the principal pyogenic organisms were systematically employed in all cases of active pulmonary tuberculosis with frequently disastrous results. In opposition to this theory of the frequency of secondary infection Besançon and Biros, at the Strasbourg Congress in 1922, maintained that the tubercle bacillus played a predominant part throughout the course of pulmonary tuberculosis, and that the rôle of secondary invaders was reduced to a few cases of pneumococcal infection or insignificant bronchitis. The present writers carried out investigations on 188 patients presenting all varieties of pulmonary tuberculosis, and found that while secondary infections were much less frequent than was formerly supposed, they were present in a considerable proportion—viz., 20 per cent.—while in the remaining 80 per cent. the tubercle bacillus was sufficient to produce every form of anatomical lesion in the lungs and all the clinical varieties of the disease, including hectic fever. The secondary infections were divided into two groups. In the first group, which consisted of 13 cases, the infection was polymicrobial, there being a collection in more or less variable quantity of different organisms, such as streptococci, pneumococci, *B. coli*, and diphtheroid organisms. Cases of this kind were almost always very severe, with pulmonary cavities, and it was difficult to say whether these secondary infections merely represented the last stage of the disease, or whether they played a part in the evolution of the lesions. In the second group, which consisted of 23 cases, the associated infection was due to a single micro-organism, such as the pneumococcus (2 cases, 1 death), pneumobacillus (2 cases), enterococcus (1 case), streptococcus (3 cases, 1 death), tetragenus (2 cases, both fatal), *B. cutis commune* (4 cases, all fatal), catarrhalis (1 case, fatal), Pfeiffer's bacillus (5 cases, 1 death), and various cocci (3 cases). In the second group the secondary invaders appear to have played an important part. The prognosis indeed in many cases seemed to depend on the nature of the associated micro-organism. While the pneumobacillus and Pfeiffer's bacillus proved to be of little danger, the streptococcus, enterococcus, and tetragenus were found in the severe and rapidly fatal cases. A Paris thesis to which attention was drawn recently sets out the sinister relation of tetragenus to fatal tuberculosis. The practical outcome of the Lyons studies is that if vaccine treatment is to be employed in pulmonary tuberculosis it should be specific. In most cases vaccine treatment by other organisms than the tubercle bacillus is not required, but in cases of secondary infection vaccine-therapy should be tried, and is all the more likely to be successful when the tuberculous lesions are not severe or extensive.

THE FUNCTIONAL CAPACITY OF THE LIVER.

WHILE the efforts of clinicians are continually directed towards the study of the functional capacity of diseased organs, the study of the hepatic functions has been somewhat neglected, although it is far more interesting and necessary than the mere physical condition of the liver. This state of things may be imputed to the fact that the results obtained have been at variance, often unexplainable and useless from a clinical point of view. Prof. Giuseppe Sabatini,[1] of the Institute of Clinical Medicine in the University of Rome, has published the results of his own investigations which seem to us to shed some light on the subject.

Prof. Sabatini recognises that the liver has not one, but five functions, the biligenetic, glycogenetic, ureopoietic, antitoxic, and proteopexic: he investigated them all by the usual well-known laboratory methods in 12 cases of hepatic disease, including diabetes mellitus, various forms of cirrhosis, jaundice, and gall-stones. In none of the cases were all the five functions affected simultaneously, nor was it possible to say whether in definite diseases there corresponded definite types of functional insufficiency either singly or gathered into special groups. In the case of cirrhosis this question could be with certainty answered in the negative, while the cases of diabetes showed an almost identical behaviour of the various functions. On the other hand, there was a profound and extensive disturbance of the hepatic functions in calculous cholecystitis. It must therefore be admitted that in this disease, apparently localised but which may cause grave disturbance of the general health, certain conditions come into play which seriously impair the action of the liver, perhaps through reflex nervous stimuli, and perhaps also through slight general infection. Investigations on a far larger scale and perseveringly carried out in this disease may help to solve this problem. The biliary function was always found altered in these patients to a slight extent, but in the diabetics it was normal, the glycogenic function was altered in some cases, normal in others—for example, in three out of four cases of cirrhosis it was found to be normal. The ureopoietic function gave results in accord with pathological conceptions; it was altered in three cases of true atrophic cirrhosis, and normal in a case of cardiac cirrhosis. In the diabetics there was invariably a disturbance of this function, probably in relation with altered metabolism not only of carbohydrates, but also of proteids. It is not improbable, however, that this function is altered in diabetics because there is in these patients a greater production of ammonia (a defence against acidosis) which necessarily changes the value of the coefficient of ureogenetic inadequacy. The proteopexic function, judged by the digestive hæmoclasis of Widal, did not give any definite or serviceable results, the hæmoclasis being sometimes positive and sometimes negative without reasonable

[1] Il Policlinico, Practical Section, xxxi., Jan. 14th, 1924.

explanation. The antitoxic function, at least in the form of Roger's induced glycuronuria showed a variable behaviour of no clinical value or particular interest for diagnosis.

The conclusion which may be derived from these interesting researches is that if it has hitherto been admitted that there is a parallelism of all the functions of the liver and a complete association between them, this view will have to be modified. Even assuming, according to the general laws of physiology, the harmony of the various hepatic functions, we have now evidence to show that this association is correct only within physiological limits. Under the action of different morbid conditions, the various functions, which perhaps have different anatomical sites in the complex and obscure architecture of the organ, do not all suffer simultaneously nor in an equal degree. So that we always find in functional exploration of the liver one or several functions more or less profoundly altered side by side with others which are absolutely normal and intact. Prof. Sabatini pleads for further studies of the many hepatic functions in order to arrive at an estimation of the functional efficiency of the organ by the adoption of definite and identical methods, so that results may be obtained which leave no gaps and are intelligible and comparable and lead to the determination of constant relationship between types of hepatic lesions and types of functional efficiency.

FUNDAMENTALS OF THE CANCER PROBLEM.

AT this stage of the cancer problem a critical selection from the enormous mass of material now collected, presented mainly in pictorial form, cannot fail to be of interest to students and practitioners. It is therefore not surprising that the Governors' Hall at St. Thomas's Hospital was filled with an audience of nearly 400 people on the occasion of the first of the four lectures on cancer being delivered under the auspices of the University of London by Dr. J. A. Murray. This lecture was a survey of the main features common to malignant growths, preliminary to the discussion of experimental and other research work in subsequent lectures. Dr. Murray's main conception of cancer is that of an aberration of the process of repair. Whether cancer arises in the covering epithelium of any portion of the body, whether it arises in the subcutaneous tissues, or from linings of the blood vessels, the same process is at work, the differences in the histology of the growth being due to differences in the tissues of origin. Dr. Murray showed lantern slides of primary and secondary growths in man and other mammals, and also in amphibians and fish, and of histological preparations demonstrating characteristic features of malignant growths. In a carcinoma which has developed from a glandular tissue the glandular structure is sometimes entirely lost, and a solid mass of cells results, but this differentiation can be reversed under suitable experimental conditions. Such a growth can be made to grow in a solid mass or made to return to glandular structure without having altered its characteristics as a growth. The superficial similarity between the histology of a carcinoma of the skin and of the development of an embryo has given rise to many of the now untenable hypotheses of the nature of carcinoma. In the early stages of malignant growths several foci of independent growth are to be found, and many growths have arisen by the coalescence of these foci; but it is interesting to note that this coalescence does not take place by the transformation of the intervening portions into cancer. It is on the interpretation of pictures as active processes—not as a final stage—that the diagnosis and interpretation of the histology of malignant new growths must rest. If cancer remained localised tissue there would be no necessity for the elaborate amount of investigation and study which we apply to it; very simple remedies would be sufficient, such as its removal when it became troublesome or dangerous. But it is the capacity for passing beyond the original site in the body and disseminating to the distant parts which makes cancer so serious a disease. Dr. Murray proceeded to discuss the occurrence and distribution of cancer. Here individual experience, he said, is of very little value. The experience of communities is required. Of all the causes of death, cancer is responsible for one-tenth or one-twelfth of the general mortality. Recoveries from cancer are practically negligible from the point of view of statistics in this country. The age-incidence of cancer, both in man and animals, is suggestive, for as we go up in years we find that the proportion of those dying from cancer, to the total of people living, rises swiftly. Comparison of the incidence and mortality of cancer in different countries is not easy. The difficulty is that we have no good grounds for believing that a number of cases of cancer recorded in any country represents truly the number of deaths in that country from cancer. There may be more deaths or fewer. There is no means of knowing what other diseases were termed cancer, or whether cancer was always diagnosed, and thus we have to read international statistics with a certain reservation. The significance of the apparent increase of cancer found in this and other countries is very difficult to interpret. It is extraordinary that the increase is not in those regions of the body—for example, cancer of the uterus—where the disease is commonest. Again, while females of 75 and upwards during the period 1851–1909 show progressive and rapid increase in the proportion of deaths due to cancer, in women of 35–45 the increase has been much less. Dr. Murray considers that we are justified in taking comfort from this observation by deducing that the factors which can produce cancer are apparently taking longer to produce it now than in the past. If the increase of cancer is significant at all, not merely due to improvement in diagnosis or the like, then it takes longer for the disease to develop than 40 years ago. That is one of the most hopeful features of otherwise ominous figures.

EPIDEMIC DROPSY IN CALCUTTA.

RECENTLY Calcutta has experienced an outbreak of epidemic dropsy, which has been the substance of an inquiry by the workers at the Calcutta School of Tropical Medicine, under Lieut.-Colonel J. W. Megaw and the staff of the Health Office, Calcutta. As a result of careful investigations, the ingestion of injured rice has been suspected as an ætiological factor in the outbreak. The disease first appeared among the women students of a medical school, who made their own messing arrangements. It was found that their rice supply came from a small dealer in a different locality. An interesting fact was discovered—namely, that the family of the dealer was suffering from generalised œdema, and that a number of people in the neighbourhood who obtained their rice from the same source were also affected. About 75 cases in all were detected. Colonel Megaw reports that all the effects which were observed went to show that the disease originated from the consumption of rice, and it was quite possible that one consignment of rice might have been responsible for all the cases. There have been many different views as to the nature and cause of epidemic dropsy.[1] In 1914, Lieut.-Colonel E. D. W. Greig, I.M.S., classified epidemic dropsy as one of the deficiency diseases, similar to beri-beri. It has also been regarded as an infectious malady, and in support of this view Dr. Bepin Brahmachari, I.M.S., has published a paper in a recent issue of the *Calcutta Medical Journal*.[2] Again, it has been widely held in Calcutta that a poison contained in an adulterated mustard oil is responsible for the condition, but no evidence of the presence of any poison has been obtained on scientific investigation. The opinion which now holds the field on the ætiology of epidemic dropsy is that rice which has been damaged by improper storage develops a mould which, when

[1] THE LANCET, 1920, ii., 1234.
[2] Calcutta Medical Journal, December, 1923, p, 519.

aken, acts as an intestinal irritant, and so affects he sympathetic nervous system. This view has been, n essentials, held by Colonel Megaw ever since he Calcutta outbreak of 1909, but conclusive proof as not yet been established. There are apparently reat practical difficulties in the way of subjecting amples of suspected rice to exact experiment. In ombating the present outbreak the Director of the School of Tropical Medicine recommends that rice should be cut out of the diet the moment symptoms of dropsy appear. In this way, it is believed, the course of the disease will always be arrested.

INSPECTORSHIPS UNDER THE BOARD OF CONTROL.

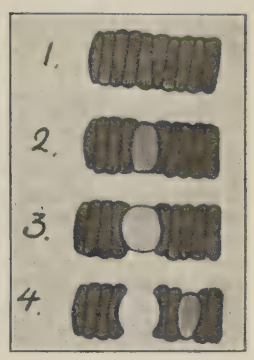
WE have before now commented upon the range—broad yet delicate—of duties carried out by the inspectors under the Board of Control (Lunacy and Mental Deficiency), and welcome the advertisement of the Board inviting applications for two more inspectors; but the terms of the advertisement, which will be found in our columns last week, have led to a representation being made to us upon two points. The words of the advertisement are :—

> The salary will be—
> (*a*) £500, rising by annual increments of £20 to £800 for men—and for women possessing a Medical qualification ;
> (*b*) £400, rising by annual increments of £20 to £650 for women.
>
> Bonus, which varies with the cost of living, is also allowed. Present bonus on salaries of £500 and £400 is £184 and £158 1*s.* respectively.
>
> The duties will include the Visitation and Inspection of Institutions, and candidates should possess a competent knowledge of the methods of Teaching, Training, and Managing Mental Defectives. A Medical qualification though not essential would be of value.

It has been pointed out to us that a differentiation in salary has been made between the sexes, and we agree that such differentiation in respect of public appointments in the medical world has now been generally condemned ; but the second point, to which more attention was drawn, is that it would appear that, for the male candidate for the post, a medical qualification, though regarded as an asset, is not to be an essential. The layman who, whatever his experience, will not have undergone a standardised course terminating in testimonials to the attainment of the standard, will be on the same footing as a candidate who has completed five or six years of intensive study. It will be agreed that many of the duties falling under visitation and inspection of institutions can be discharged by laymen, but it will not be obvious how a candidate is to prove experience in the management of mental defectives if he has had no special training in the phenomena of mental disease. The posts do not appear to us to carry a salary that will be attractive to medical men with special claims over and above a general medical training, which would seem to us to furnish a further reason for not minimising the scientific status to which they rightly attach importance.

A RE-DISCOVERED BLOOD CORPUSCLE.

Dr. Robin Fahraeus, whose work on the rate of sedimentation of the erythrocytes has given us a most valuable test of disordered metabolism, publishes in *Acta Medica Scandinavica* (1924, l., 12) an account of a blood corpuscle which modern works on the blood appear to ignore. This corpuscle seems to be a red corpuscle which has undergone hæmolysis, and, curiously enough, it is to be seen in every fresh preparation of blood, or, to be more accurate, its position is to be seen, for the corpuscle itself, having the same refractive index as the plasma, is invisible in this medium. In a strongly aggregating specimen of blood an isolated rouleau may be seen with a gap of quite the same appearance as the surrounding plasma. Yet the rouleau behaves mechanically as a coherent string, swaying to and fro with the currents in the preparation. The two corpuscles bounding this gap are curved inwards, although the last corpuscles at the two ends of the rouleau are convex outwards, owing to the surface-tension. The two concavities bordering the interval outline a sphere with a radius of about 3μ. These colourless corpuscles are more easily found in strongly aggregating blood than in blood of normal rouleau formation, and the obvious fact that they aggregate with the red corpuscles makes it probable that they are spherical "red" corpuscles without hæmoglobin. Similar bodies may be created by the artificial hæmolysis of the red corpuscles, a fresh preparation of blood being subjected to the heat of a strong source of light such as an electric arc lamp. Under these conditions a red corpuscle begins to change its appearance in the middle of a rouleau, swelling and becoming transformed from a disc into a sphere, turning more and more pale. This process is indicated in the accompanying diagram. When the corpuscle has become spherical there is only a trace of faint yellow left, and this fades away soon. In the case of the colourless corpuscle seen in an ordinary blood preparation it is not clear whether it represents an intravital process or not. Dr. Fahraeus favours the former view for various reasons, and he believes that this corpuscle represents the final stage in the life-history of the erythrocyte, of which we have hitherto been in ignorance. Though this corpuscle does not figure in modern works on the blood cells, it was long ago described by Dr. Richard Norris, professor of physiology at Birmingham, and the father of microphotography in hæmatology—a process he introduced in 1877. From a study of his photographs of fresh blood preparations he discovered a formed, colourless element of the same size as that of a red corpuscle. Almost at the same time Bizzozero published his classical discovery of the blood-platelets, and Norris at first thought that the two structures were identical. In his principal work, published in 1882, Norris described his corpuscles as the nuclei of the lymph cells which had lost their protoplasm and represented early stages of the red corpuscles into which the colourless discs were transformed by the absorption of red pigment. It will thus be seen that, though Dr. Fahraeus makes no priority claim to the discovery of this corpuscle, his opinion of its past, present, and future characteristics is very different from that of its original discoverer.



DIATHERMY IN ANTERIOR POLIOMYELITIS.

OF late years much stress has been laid on the importance of the relaxation and the prevention of stretching of paralysed muscles in cases of anterior poliomyelitis. And no doubt, rightly laid, although attention has thereby been diverted from the use of physical agents, other than massage, in the after treatment of this malady. The older forms of electrical treatment—viz., by the faradic and galvanic currents—are still sometimes applied, but they are prescribed solely for the purpose of causing the paralysed muscles to contract and undergo artificial exercise. Recently, Prof. H. Bordier, of Lyons, has remarked on the value of diathermy in infantile paralysis. It is well known that recovery from paralysis is greatly retarded by cold ; the heat generated by the diathermy current in its passage through the tissues is retained longer than the heat conducted to or radiated to the tissues from external sources. Heat from external sources does not cause a rise of temperature beneath the skin, whereas that produced by diathermy is actually generated within the tissues traversed by the current, both superficial and deep. Bordier states that the cold paralysed

limbs retain the heat produced in them by diathermy for long periods, amounting to 24 hours or more. He recommends the use of diathermy as a valuable aid in the treatment of the paralysed muscles in anterior poliomyelitis. In a lecture on this subject, delivered last week at the Hospital for Sick Children, Great Ormond-street, Dr. C. B. Heald gave particulars of four cases which improved considerably after the replacement by diathermy of other forms of physical treatment. The improvement was particularly evident in the condition of the limbs, the warmth being retained during the intervals between the applications of diathermy, while the power of voluntary movement was regained. Dr. Heald stated that he applied diathermy not only to the limbs, but also to the spinal cord in the region of the lesion, pointing out that this application to the spinal cord probably causes an increase of blood-supply to the site of the lesion. He quoted the statement of Ruhrah that the virus of poliomyelitis is destroyed by exposure for half an hour to 45° to 50° C., and suggested that the heat produced by diathermy in the spinal cord might lessen the toxicity of the virus.

THE SALARY OF THE ASSISTANT TUBERCULOSIS OFFICER.

WE have received some letters pointing out that the administrative county of East Suffolk, in an advertisement which appeared in our columns last week, does not offer to intending applicants the minimum salary according to the adopted scale. The wording of the advertisement was not clear to us, and we regret its insertion, but the letter warning us of its nature was not received until two days after we had gone to press. One of our correspondents reproaches us, also, in the matter of an advertisement for a temporary post of the same nature, but that advertisement was not accepted until we had ascertained that there was neither official nor local objection to its insertion.

THE ROYAL SOCIETY.

AMONG the 15 candidates selected by the Council of the Royal Society for election this year are Mr. Joseph Edwin Barnard, Dr. Mervyn Henry Gordon, and Prof. Charles Spearman. Mr. Barnard is honorary director of the Department of Applied Optics at the National Institute of Medical Research, and lecturer on microscopy at King's College, University of London. Dr. Gordon is consulting bacteriologist at St. Bartholomew's Hospital, and his name is particularly associated with the classification of different types of the streptococcus and the meningococcus, and with the investigation of filtrable viruses, particularly in relation to influenza. Prof. Spearman is Grote Professor of Mind and Logic in the University of London (University College), having previously been Reader in Experimental Psychology.

DONATIONS AND BEQUESTS.—By the will of the late Miss Matilda L. Putt, of Streatham, the testatrix left among other bequests £1000 each to the National Hospital for the Paralysed and Epileptic, Bloomsbury, and the British Home for Incurables, Streatham Common, S.W.; £500 each to the Torbay Hospital, Torquay, for the maintenance of the Bramford Speke Bed already given by her, the South Devon and East Cornwall Hospital, Plymouth, the Seamen's Hospital, Greenwich, Dr. Barnardo's Homes, and the Royal Society for the Prevention of Cruelty to Animals. The testatrix stated that in the event of any of the above hospitals, by reason of any Parliamentary legislation or other causes, ceasing to be supported by voluntary contributions, and managed by the State, or supported by the rates or grants from the State, the legacies to such institutions are to be void.—Among bequests left by the late Mr. John Greaves, of Manchester, are: £1000 to the Manchester Royal Infirmary; £250 to St. Mary's Hospital; £150 to the Hulme Infirmary; £500 each to the Manchester Children's Hospital and Dispensary, Pendleton and Henshaw's Blind Asylum; £200 each to the Manchester and Salford Blind Aid Society and the Salford Royal Hospital.—The Chelsea Hospital for Women has received a grant of £400 from the trustees of the Zunz Bequest towards the maintenance of its Annie Zunz Wards.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LX.—THE TREATMENT OF NEPHRITIS.

II.—ACUTE AND CHRONIC FORMS.

IN the light of the considerations advanced last week it is obvious that the general treatment of nephritis must depend largely on the nature of the case. In acute nephritis, treatment may to a large extent be guided by the severity of the condition, but in all subacute or chronic lesions the exact procedure to be adopted depends largely on the state of the renal function as revealed by the clinical condition and by renal tests. In all cases it goes without saying that every possible source of local infection should be explored, for a severe renal lesion may be the result of such conditions as chronic tonsilitis or a septic tooth. The general principles underlying the treatment of acute nephritis are as follows.

Acute Nephritis.

(1) Keep the patient absolutely at rest in bed; see that he is warm and suitably clothed, preferably with flannel next the skin. During examination by the doctor, great care should be taken to prevent undue exposure and chilling of the body. Give 2 gr. of calomel followed by a saline purge.

(2) Give a moderate amount of fluid, but no attempt should be made to give large amounts of fluid with a view to washing out toxins. For the first day or two, one pint *per diem* of fluid should not be exceeded if possible. The nature of the fluid does not matter much, and home-made lemonade, barley water, or very weak tea is suitable. If thirst is an important feature rather more fluid must be allowed.

(3) During the early acute stage the patient must be dieted just like any other case acutely ill. At first, it is best to give milk diluted one-third with soda-water, barley-water, or lime-water, but very soon bread and butter, Benger's food, and other starchy materials may be given. The nature and amount of food allowed must depend largely on the state of the patient's stomach and on the intensity of the symptoms. When the more acute condition has passed over the diet should be increased, and should consist largely of such articles as potatoes, rice, tapioca, bread and butter, custard, sweets, and cream. As improvement goes on fish should be added, soon to be followed by chicken and other meat proteins. In favourable cases a patient should be able to return to a more or less normal diet in about six to eight weeks. The addition of protein to the diet may be regulated by estimations of the blood-urea; as the blood-urea decreases towards the normal level the proteins may be increased.

(4) If œdema is severe, and the amount of urine passed continues to be very small, the condition may be helped by the use of such purgatives as pulv. jalap co., or, in young people, cascara sagrada or pulv. glycyrrhizæ co. Local pain may often be relieved by hot fomentations and poultices, or by these combined with cupping. Sweating may be induced by a hot-air bath or hot packs, or, if the patient is strong enough, by a hot-water bath. These baths should not last more than 20 minutes, as there is frequently some danger of cardiac collapse. During the process the pulse should be carefully watched; if faintness or collapse comes on the procedure must be stopped. If the œdema is intense, and the usual methods fail to relieve the condition, the administration of pilocarpine (1/10 to 1/6 gr.) is sometimes advocated, but its use is not devoid of danger, and it should only be employed under exceptional circumstances. Occasionally its use may set up œdema of the lungs, a most dangerous complication which may sometimes yields to the injection of 1/100 gr. of atropine. Hot air and other baths, though frequently

employed, are not often necessary, and it is doubtful to what extent they relieve the condition, but they often seem to make the patient feel more comfortable. If necessary, fluid must be removed from the limbs by the use of Southey's tubes, or from the body cavities by tapping. Southey's tubes should not be used except as a last resort, for they may give rise to sores which become infected and are difficult to heal. In extreme cases, decapsulation of the kidney has been resorted to; its value is very doubtful, though in a few cases dramatic results have been claimed. It is a procedure that cannot be recommended in acute renal lesions. Vomiting may be fairly severe in acute nephritis, and seems frequently to be largely dependent on the œdema and ascites. When this clears up the vomiting generally disappears. It is best treated by giving as little fluid as possible with the food, or, if very severe, by giving no food at all by mouth for a day or two. The usual alkaline remedies, especially when combined with small doses of hydrocyanic acid, are often very efficacious, and sometimes great relief is obtained by tapping the abdominal cavity and thus relieving the pressure of the fluid on the viscera. Drop doses of weak iodine tincture or of liquid carbolic acid given in water are occasionally useful. When vomiting is due to retained toxins it disappears when the kidneys regain their excreting power.

(5) Sometimes acute nephritis, especially when associated with marked œdema, gives rise to convulsions and a so-called uræmic state. Here the best treatment is the removal of 15 to 20 oz. of blood by venesection. Convulsions in acute nephritis generally cease as the result of this procedure, and the patient usually does quite well. Blood-letting is of much more value in acute nephritis than in the chronic condition, and probably might be more frequently practised than it is at present with benefit to the patient.

Chronic Nephritis.

The treatment of subacute or chronic nephritis resolves itself almost wholly into considerations of general régime and suitable diet. Complicated and puzzling as chronic nephritis may be from the clinical standpoint, modern research has shown that there are two quite distinct types of the disease, and that these two types can frequently be differentiated by renal tests.

The Hydræmic Type.—In one type the characteristic and prominent symptom is *œdema*; there is frequently a difficulty in excreting water and salt, but no difficulty whatever in excreting nitrogenous waste products. This hydræmic type is always associated with the presence of a very large amount of protein in the urine.

The Azotæmic Type.—In the other variety of renal disease there is frequently no hindrance to the passage of water and sodium chloride, but a distinct failure to excrete nitrogenous waste products. The urine in this azotæmic type frequently contains but a very small amount of protein; unlike the hydræmic variety, it shows a marked tendency to be accompanied by cardio-vascular complications, and sooner or later, if the patient survives, uræmic manifestations set in.

Before deciding on the line of treatment to be adopted in these different lesions it is essential to ascertain what the nature of the condition present in any patient really is. This information, as I have more fully explained elsewhere,[1] is best obtained by the use of modern renal tests. If a patient suffering from extreme renal œdema shows a favourable blood-urea concentration, and gives good results with the other tests, there can be no doubt that the best treatment is to put the patient on a good diet composed largely of protein. Often this increased diet may, with advantage, be combined with 10 to 15 g. of urea given by mouth twice daily. This dose may be kept up for a week, when it should be left off for a few days, to be continued at intervals for other short periods if necessary. It is wonderful how rapidly the œdema sometimes disappears with such treatment; in other cases one must admit that the results are disappointing, but when this is the case it will generally be found that the patient is not suffering from a pure hydræmic condition, but shows evidence of azotæmic or interstitial disease as well.

In hydræmic cases not very much can be done by means of hot air and other hot baths. In this type of case they are frequently dangerous, and cardiac failure, in my experience, is by no means a rare accident. They should never be used if there is any suspicion of cardiac weakness.

The diet in chronic interstitial nephritis must be guided by the extent of the lesion and by the state of the renal function. When the case is a very advanced one, the usual low protein diet is probably best, but in many patients experience shows that the present custom of prescribing a very low diet often does harm. In such patients a marked improvement in general health can frequently be brought about in a few weeks by allowing a good diet containing a fair amount of protein. No doubt the tendency to anæmia, so marked in many cases of renal disease, is frequently due to an insufficient diet, and probably more harm is done in the milder forms of nephritis by the poor diet alone than by the renal disease itself. On the whole, the tendency now is to feed our nephritic patients rather better than we did, and not to restrict protein too much unless the condition is really advanced.

Conclusion.

The various other therapeutic means employed in chronic nephritis are similar to those referred to when discussing the acute condition. The necessity for great care in guarding against cold and other deleterious influences is obvious. In the light of our present knowledge the factor which seems to play the largest part in the treatment of chronic nephritis is that of diet, and in all but extreme cases a good deal can frequently be done to contribute to the patient's comfort and welfare by the use of a suitable dietetic régime based on the principles outlined above.

HUGH MACLEAN, M.D., D.Sc., M.R.C.P.,
Professor of Medicine, University of London,
St. Thomas's Hospital.

Special Articles.

VENEREAL DISEASE ABROAD.

The Impending Collapse of the Campaign in Germany.

A JUSTIFIABLY lugubrious account is given by Dr. Häffner[1] of the effect the present political crisis in Germany is having on the venereal disease campaign in general, and the dispensary system in particular. This state of affairs is the more deplorable as the dispensary organisation had become remarkably efficient towards the end of the war, and there was every hope that the control exercised by the dispensaries over individual patients would gradually be tightened. Now, according to Dr. Häffner, it is gradually being relaxed, and there seem to be well-grounded fears that the whole dispensary organisation may be dissolved, and patients in an infectious state will be more or less free to pass the disease on to others without much fear of detection. By 1919 there were as many as 138 dispensaries whose clientèle could be counted by the hundred thousand. In the Dortmund dispensary alone 3385 first examinations were made in 1922 and 5271 re-examinations. Courses of treatment were given in 4602 cases. In this and other German dispensaries an organisation was established to secure permanent supervision of the subjects of venereal disease for whom abortive and secondary courses of treatment were provided. It was anticipated that the

[1] Deut. med. Woch., Jan. 18th, 1924.

administration of the new venereal disease law would be mainly in the hands of the dispensary officials and that, as an effective weapon, the fate of the new law would depend on these dispensaries. Originally they were financed by local and central authorities and by the insurance societies. The central authority bore the lion's share of the expense, defraying most of the cost of examination and treatment, towards which the insurance societies also contributed a certain sum. But since 1920 the central authority has disowned one obligation after another, and the other parties to the financing of the dispensaries have also found it convenient to curtail their contributions. In 1923 it was decided in one area that the insurance societies must be entirely responsible for the treatment of their members, the central authority being prepared to provide only examinations and advice free of cost. The result of this decision has been that the insurance societies have failed in many cases to send their members to the dispensaries, being inclined to regard these dispensaries as too great a drain on the resources of the societies. Already about two-thirds of the patients in the Dortmund dispensary have been lost sight of for these reasons, and the time seems not far distant when this dispensary will have to be closed. Already in Baden the dispensaries have been closed, and doubtless the same fate awaits many of the other German dispensaries. When this state of affairs is compared with that which now exists in Great Britain, the points of similarity are striking enough to warrant the suspicion that it is not merely national bankruptcy that is responsible for the change. Post-war inertia and official lassitude are here counteracted by the activities of societies expressly devoted to keeping interest in this subject alive.

Infection Statistics in Switzerland.

The inquiry, conducted by the Swiss Society for Combating the Venereal Diseases, into the frequency of the venereal diseases in Switzerland is the subject of an interesting paper by Dr. W. Feld,[2] who points out that this inquiry covered the period October, 1920, to September, 1921, and that more than three-quarters of the Swiss doctors helped in the compilation of the statistics. Altogether 15,607 cases were thus notified, gonorrhœa being represented by 60 per cent., syphilis by 40 per cent., and ulcus molle by 0·6 per cent. There were four cases of venereal disease, recent or old, for every thousand inhabitants. Striking differences in the distribution of the disease in town and country were observed; only 15 per cent. of all the cases were bucolic. Three-quarters of all the patients lived in towns with a population of more than 10,000 inhabitants, and when to these towns smaller industrial centres were added, 85 per cent. of all the cases could be referred to town areas. In towns with a population exceeding 50,000 the incidence of venereal disease was 10·7 per 1000, whereas in small industrial centres it was only 2·5, and in country districts only 0·9 per 1000. The ratio of male to female patients was as 68 to 32, and among the new cases first diagnosed in the year under review there were as many as 75 males to every 25 females. There may be various reasons for these differences in the sex incidence of recent and old-standing cases; a comparatively great number of cases of gonorrhœa and syphilis in women probably escape detection till they are of old standing. About three-quarters of all the patients were in the twenties and thirties, and most of them were in the twenties. Classification of the patients according as they were single, married, widowed, or divorced brought out some curious facts. The divorced headed the list with 13 patients per 1000 inhabitants. The single came next with 7 per 1000, then the married with 3 per 1000, and finally the widowed with only 2 per 1000. But when the patients were classified with men and women in separate classes it was found that the incidence of venereal disease was higher among widowed men than married men—higher even than among single men between 40 and 49. But among the women the widows showed the lowest rate of infection. It is calculated that about 30 per 1000 of young men in the twenties living in large Swiss towns contract gonorrhœa every year, 5 to 10 per 1000 contracting syphilis in the same period. It is also calculated that there are about 37,000 persons in Switzerland who, at some time in their lives, have contracted syphilis. Of these about 8500 are undergoing treatment. There are also about 12,000 undergoing treatment for gonorrhœa, and every year there are about 100 new cases of general paralysis.

With regard to the mode of infection, Dr. Feld calculates that 80 per cent. of the married women traced it to their husbands, while 7 per cent. were infected before marriage, and 13 per cent. contracted venereal disease by extra-marital relations. Of the divorced women, 54 per cent. attributed their infection to their former husbands. In the case of the male patients, however, it was very exceptional for the husband to trace the disease to his wife; 40 per cent. traced it to prostitutes. It was found that the part played by prostitutes in spreading disease varied considerably with the different social classes; business men, clerks, and artisans were comparatively seldom infected by prostitutes, whereas the scientific professions, students, and waiters referred their infection in a comparatively great number of cases to prostitutes. About half the students had contracted venereal disease abroad. Though these figures do not, of course, include every case of venereal disease in Switzerland, they evidently give a very accurate picture of the comparative incidence of venereal disease under a variety of different conditions.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh: Special Out-patient Clinics.

THE diabetic out-patient clinic recently started under Dr. Murray-Lyon makes the third of the special out-patient clinics now in operation at the Royal Infirmary, Edinburgh. The other two are for cases of lupus and for tuberculosis respectively. The lupus clinic, the father of them, was started by Sir Norman Walker in September, 1919. The scheme was conceived just before the war, but for obvious reasons it was not possible to get it thoroughly under way until after the war was over. The tuberculosis clinic was opened by Sir Robert Philip in October, 1921, with the assistance of Drs. Fergus Hewat and Jack Simpson, and is now under the charge of Dr. Hewat. The plan of working in all three clinics is largely on similar lines: the patients are seen in turn by the physician, progress noted, and necessary treatment carried out.

Lupus.—The lupus clinic has a roll of about 120 patients, with an average weekly attendance of about 40. An attendance roll is taken and patients must attend regularly, as instructed. Each patient is examined by the doctor, and changes in his condition are noted on his case-card along with any treatment carried out. About half the patients are being treated with tuberculin, and a number are now receiving Tungsten lamp treatment. The period of reporting varies from once a week to once every three months. Suitable arrangements are made for patients requiring hospital treatment and nursing or other medical attention.

Tuberculosis.—The tuberculosis clinic is run on very much the same lines. The cases are mostly children with abdominal tuberculosis and tuberculous glands. There are some 240 on the roll, and the average weekly attendance is 60. For diagnostic purposes each patient is rubbed with 10 per cent. Moro's ointment, and if this fails to produce a reaction 40 per cent. is used. The routine is as follows. Each patient is weighed. The weight is charted on his case-report, and he is then sent in with his case-report to the doctor for examination, and progress is noted. After this he is rubbed with Moro's ointment, beginning with 10 per cent. and working up to 40 per cent. The inunction is the only

pecific treatment, tuberculin injection not being sed. Instructions are given as to rest, exercise, diet, esh air, &c. Arrangements for sanatorium treatment re made for acute cases and for those whose progress ot considered satisfactory. The cases are all recommended by practitioners or from the wards of the nfirmary.

Diabetes.—The diabetic clinic resembles in general he other two. Although it has only been going a ew weeks there are already about 70 on the list, with n average weekly attendance of 30. Each patient rings a specimen of urine collected over 24 hours, hich is tested for sugar and acetone. The patients re then seen by the doctor, their progress or otherwise stimated, and the diets raised, lowered, or repeated as ay be required. The special diets, as suggested by r. Murray-Lyon, are used. Dietetic treatment is hiefly employed, insulin not being used except in ases previously investigated. Severe cases requiring nsulin treatment are put on the waiting list for dmission, and in the interim are put on dietetic égime, so that when they come to be admitted the ecessary time of in-patient treatment is materially ssened.

The advantage of this organised method of treating atients suffering from diseases requiring lengthy reatment lies in ensuring a concentrated study of he special disease, and in obtaining correct and ersistent treatment, which is so essential for satisactory results. The amount of time and labour saved s very considerable, the collecting of statistics is reatly facilitated, opportunities for mass experiments re afforded, and from the point of view of teaching he method offers many advantages. From the conomic and social standpoint it would seem to rovide the solution to the problem of dealing with hronic disease. The more effective treatment of hese conditions should materially lessen the amount f economic disability caused by them. At the ame time, from the teaching aspect it cannot be gnored that this scheme has the disadvantage of ithdrawing such cases from the ordinary out-patient lepartment, where the student is more likely to see hem, and necessitating his attendance at a number of pecial clinics which may be held at times which nake it difficult for him to attend.

Public Health Administration.

From the Scottish Board of Health comes the nnouncement of the loosening of governmental urse strings towards the public health services. A public health circular of February, 1921, imposed he restrictions (as stated in the Public Health ircular No. 1, 1921) on the development of grant-ided services, such as maternity and child welfare, uberculosis, venereal diseases, welfare of the blind, nd port sanitation have now been withdrawn. The oard will accordingly be prepared to consider on heir merits developments of these services which ppear to local authorities to be advisable and are ithin their powers. With the approval of Parliament, the Board will make grants for approved xpenditure on such developments at the rate applicable to the service and subject to the usual conditions. In regard to grant for the treatment of uberculosis, local authorities are informed that rant at the rate of 50 per cent. will be paid on all pproved expenditure incurred by them in the year 923–24, subject to the usual conditions. It is to be oped that these increased opportunities for advance ill be followed by correspondingly satisfactory esults.

ST. GILES'S HOMES FOR LEPERS IN ENGLAND.—his asylum, situated in a remote part of the country, the nly hospital for lepers in England, is at present struggling r want of sufficient funds. A generous donor has offered s. for every £1 that is collected up to £4000, and it is hoped hat the homes may benefit to the full extent of this offer. Donations may be sent to the Hon. Secretary, Mr. R. C. olton, 10, Old Jewry-chambers, London, E.C. 2.

"Audi alteram partem."

INDUSTRY AND MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Factory law is a prominent part of public health legislation; it aims at preserving the health of the industrial population upon whose activity and productivity the community depends. We are right to be proud of our code of industrial legislation, which has been the model for similar legislation in all other countries; and the more we congratulate ourselves upon having been pioneers the more jealous we should be to remain in the front, but conditions in industry change rapidly, as has been shown in the series of articles, the last of which appeared in your issue of Feb. 23rd, and with industrial progression come new circumstances requiring new enactments. The subject is topical at the present moment, when a consolidating Factory Act may shortly be expected to be before Parliament.

Much has happened since 1901 when the present main Act was passed; supplementary Acts have been passed and new powers have been taken; experience gained in other countries has come to hand; a new spirit, bringing together employers and employed, has arisen in industry; new knowledge has been acquired and is still being acquired with regard to the economic value of the human machine; physiological laws underlying activity are being made manifest. There is to-day a greater tendency than in the last century for legislation to be based on the foundations of research rather than on special or immediate needs for remedying admitted evils. Medical research with regard to industrial activity has advanced, but so far the services of the medical profession have been but little used by industry—except in legal disputes for compensation claims. A staff of five medical inspectors of factories seems inadequate to control the health of some 7,000,000 factory workers, while the miners are left without any medical inspection. Truly there are certifying factory surgeons whose post was created as long ago as 1844; but their duties have not developed with the development of knowledge. Their main function to-day is to certify as fit for work young persons under 16 years of age; but as these young persons are not seen again, no chance is given for checking decisions; while for those employed in mines even this perfunctory supervision has never been established. Industry, familiar with these meagre duties, would appear to judge thereby the value of professional services, and to be content.

At present the post of certifying factory surgeon would seem to be of the nature of a vestigial remnant of historical interest, save where individual enthusiasts assume on high motives greater responsibility. The industrial doctor, practically unknown in this country, is well recognised in America where his services are appreciated to be an economic asset, and where there now exists a flourishing Association of Industrial Physicians and Surgeons. Doubt may be expressed as to the expediency of forcing a medical service upon industry by legislation; the relation of the State to its component parts cannot be summed up in the word "coercion." Nevertheless, obstacles in the way, such as the post for the certifying factory surgeon, should be removed and power might be taken, as in the case of welfare supervision, to call for medical supervision, which to commence with might be demanded for first-aid stations in large factories and subsequently be extended in the light of experience gained. Industry came into existence to provide health needs; these needs created industry. Industry should be, and indeed is, our greatest organisation for maintaining health; but it requires guidance.

I am, Sir, yours faithfully,

Cardiff, Feb. 19th, 1924. EDGAR L. COLLIS.

THE POSITION OF PSYCHO-ANALYSTS.

To the Editor of THE LANCET.

SIR,—The letter signed "A Teacher" in your issue of Feb. 23rd raises questions of interest even to those of us who have no direct concern with psycho-analysis. "A Teacher" implies that current methods of controversy are ethically unsound and intellectually incompetent. Both implications appear to me to be correct. Perhaps the ethical problem may be illustrated by a hypothetical case. The measurement and correction of errors of refraction are part of the ordinary work of medical practitioners, and retinoscopy is a method used by them. Errors of refraction are also treated by medically unqualified persons, and some of these, too, may possibly employ retinoscopy. If two Fellows of a College of Physicians of Surgeons wrote a treatise denouncing the evils wrought by persons termed retinoscopists but not otherwise specified, if the authors permitted that treatise to be reviewed in the daily press and subsequently wrote a letter in a daily paper containing further denunciations of retinoscopists, very few medical men would hesitate to describe the authors' conduct as grossly unethical. It is not clear to me that the substitution of the word psycho-analyst for retinoscopist and the consequent transformation of fiction into very recent fact alters the ethical position.

The intellectual incompetence of much Freud-supporting and Freud-demolishing printed matter—it cannot be termed literature—is obvious enough. Not to complicate matters, consider a single branch of the subject, that concerned with the interpretation of dreams. Some supporters of Freud's *Traum-deutung* almost appear to think that the method of Mr. Sherlock Holmes is scientifically adequate. It is, of course, mildly interesting when the Mr. Sherlock Holmes of real life deduces from the unbrushed condition of a hat that its owner's wife no longer loves him, and is able to say truthfully that the wife of the owner of the particular hat investigated really disliked the owner. But before we can attach great diagnostic value to the amount of dust upon hats in elucidating conjugal relations, we shall certainly need—dare I say—*statistics* of the distribution of many dusted and undusted hats in association with a distribution of wives loving and neglectful.

But the Sherlockian method, although not reasonable, has at least some affinity to reasoning. There is a lower deep. One may, for instance, set out the variety of symbolical interpretations which Freud and his adherents have assigned to the same or similar dream contents and assert that this variety *proves* what nonsense the whole business is. This enumerative process, sweetened by jokes of varying merit, is widely used. But its power as an instrument of research has not yet been fully appreciated. Thus it follows at once from the fact that in English the same word—e.g., box—means ten different things according to the context, that our mother tongue is mere gibberish. It is also quite plain that any man who pretends to effect the differential diagnosis of pneumonia and typhoid fever by purely clinical means is a quack, because Osler himself admits having brought a case before his class "one week as typical pneumonia, and a fortnight later shown the same case as undoubtedly one of typhoid fever." Much popular anti-Freudian writing is on this puerile level; but there is criticism which, while insufficient, is at least rational. We assess the value of diagnostic rules in bodily disease, sometimes by appeal to post-mortem verification, more often by the emergence, after the rule has been applied, of signs or symptoms which we deem crucial. What analogous tests are applicable to the Freudian rules? If I dream of ascending a moving staircase, how can I be sure that the meaning is erotic, how can I know that the "free associations" which, by all returning to a sexual *motif*, support that interpretation do not so return because I am unwittingly dragging them there, having read Freud's book? The answer is, of course, that I cannot be sure.

Two methods of rational examination have been suggested. A. v. Muralt[1] wrote down the dream of a patient and the "free associations" of the leading contents; he sent the transcript to a number of psycho-analysts, and invited them to interpret the dream and give a diagnosis. The author considered the concordance between the interpretations and the subsequent evolution of the case satisfactory. Another method is to do what Freud and de Sanctis (not a Freudian) have done, and what the late Dr. Rivers was doing—viz., record and study one's own dreams, not for a week or two, but for years. The collation of a large number of records might help us to reach, not the truth, but a field in which truth could be sought.

At present we are deluged with a flood of silly little books and articles the authors of which have made no independent investigations whatever, and frequently cannot even read the language in which much of the literature of the subject is published.

I am, Sir, yours faithfully,

Loughton, Feb. 24th, 1924. MAJOR GREENWOOD.

To the Editor of THE LANCET.

SIR,—When one finds in the same issue of THE LANCET Dr. Crichton Miller ranged on the side of those who urge that the study and treatment of emotional disorders should be approached from a physical point of view, and "A Teacher" who views the subject from the standpoint of orthodox medicine, advocating the serious consideration of the claim of psycho-analysis to full recognition as an essential factor in current medical science, the hope revives that the long overdue reconciliation between the dissociated halves of the science of healing may at last be within sight.

Dr. Miller, whose right to speak for psycho-therapy can hardly be questioned, disarms its opponents by seizing their weapons and himself attacking the position of those psycho-therapists who bring ridicule upon their profession by ignoring the physiological aspects of nervous disease. This he does with such vigour that he is moved to offer excuse for his attack, on the ground that "the therapeutic contribution of analytical psychology is too important and its possibilities too valuable to be exposed to criticism and even ridicule because of the apparent incapacity of certain analysts to correlate their psychological theory with physiological observation." Such criticism from such a critic will be welcomed by most level-headed psycho-therapists; yet the errors for which Dr. Miller flagellates his colleagues are such as occur very readily amid the dust of conflict. When the analyst who has first-hand evidence of the causation of hyperthyroidism by emotional stress is subjected to ridicule at the hands of endocrinologists and surgeons, who themselves have first-hand evidence of the causation of emotional stress by hyper-thyroidism, he very naturally resents the illogical intolerance of his opponents, and perhaps retorts that thyroidectomy in such cases should be and will be punishable as a criminal assault. The contestants on both sides fail to recognise clearly that they are dealing with a vicious circle. The therapeutic problem in every case involves the breaking of this circle at the point or points most accessible to attack. The ideal treatment may be a complete psycho-analysis; in practice this is usually impossible, and failing a sufficient measure of control by organo-therapy an honest psycho-therapist will invite the opinion of a surgeon as to the feasibility of a partial thyroidectomy.

But in the heat of conflict the psycho-analyst, like his opponents, too often adopts a self-sufficient and partisan attitude, and even Dr. Miller, in the very act of taking the lead in the direction of reconciling the rival claims, is not quite guiltless of setting them one

[1] Schw. Archiv f. Neurologie u. Psych., 1922, xi., 13.

gainst the other. But this is a minor criticism; he main point is that Dr. Miller, with an assured lace among the psycho-therapists, has opened the oor to a sane review of their methods from the point f view of general medicine, while "A Teacher" eads the way in equally sane criticism of their pponents as such. I am concerned to support ather than to criticise their action; for surely it is bvious that the conflict between the claims of the ody and the claims of the mind can be settled only y mutual acceptance and agreement. If the aterialist is able to establish some such position s that the mind is the sum of the conscious and otentially conscious reactions of the physical body, t does not follow that the mind is "nothing but" his. In ordinary human experience one mind can ave no traffic with another except by way of the nteractions of the corresponding physical bodies. t does not follow that there is no such thing as mind. gain, the fallacy of assuming that a thing ceases to e when it is analysed and understood is very revalent. An eminent endocrinologist addresses a neeting of psychologists and gives them much aluable and interesting information as to the unctions of the internal secretions; but he appears o expect them either to deny his contention that motional reactions are in large measure a function of nternal secretions, or to accept his corollary that the sychological study of emotional reactions is super-lous. Lest I should be judged guilty of that partisan ttitude which I deplore, let me add that psycho-nalysts appear to me to be equally liable to the bove-mentioned fallacy. They may, for instance, ell you that there is no such thing as a herd instinct, ecause they have been able to show that the reactions ncluded under this name have been built up from elf-preservation and sex instincts. But is this any roof that the herd instinct has no real existence? t might with equal reason be maintained that there s no such thing as a man, because his body is "nothing ut a colony of cells."

Physical and psychological schools alike have great eed of the recognition of the positive truths estab-ished by each other; their mutual negativism has asted too long, and it is devoutly to be hoped that it s nearing its end.

I am, Sir, yours faithfully,

J. NORMAN GLAISTER.

SMALL-POX AND VACCINATION.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 16th there is a sentence n Dr. A. H. G. Burton's letter which has caught my ttention. He says "we are not quite sure whether he American type of small-pox breeds true." My rst case of small-pox was notified in Bentley-with-arksey U.D. on August 25th, 1922. I had then and or some time after the same doubt about the type f small-pox breeding true. Since the date in ques-ion up till Tuesday last there have been 185 cases otified in the districts of which I am medical officer f health. There have been no deaths.

I am quite sure this particular type of small-pox—all it American or what name you like—is small-ox, and breeds true to type. I may add that the resent outbreak of small-pox has interested me very uch, as it was my good fortune to be a resident edical officer at the City of Liverpool Fever Hospital, he Dingle, in 1902–03, when the hospital was emptied f scarlet fever and diphtheria and the whole 400 eds given up to small-pox. Speaking from memory, ver 2000 cases passed through the wards. The icture presented by many of the unvaccinated cases esembles those shown in the late Dr. Ricketts's ork on the "Diagnosis of Small-pox," Plates LIII., IV., and LVI. Small-pox of that epidemic left on ıy mind the indelible impression that it was, at any ate in the unvaccinated, both a "killing disease" nd a mutilating one to the survivors.

The type of small-pox we are now experiencing is neither a killing nor a mutilating one. This was brought home to me as early as Oct. 1st, 1922, when I was called into consultation and saw an unvaccinated father, aged 33, in bed with his unvaccinated infant, aged 3 months; both were covered with a small-pox rash of medium density. The infant had it worse than the father. Both recovered and came out of hospital on Nov. 3rd. The mother brought the child to see me on discharge, and it was with difficulty I could find any scars.

Another thing has struck me about the present type is that the history of the invasion is most important. The invasion is definite and severe. When a collier, in the pink of health, has to leave off work for a headache or backache, you may be sure that it is a "knock-out" one. The next thing is that the number and character of the individual lesions are often quite insignificant considering the severity of the initial symptoms. But the lesions occur in the classical positions if looked for, but they are often quite scanty even in the unvaccinated.

Lastly, a word about "bad arms." I have seen a good few in my own practice and that both of public vaccinators and private practitioners. They usually occur in adults. I have seen most successful results in families amongst the younger ones and "bad arms" amongst the elders when vaccinated at the same time with the same lymph. I draw attention to these facts as there is no use burking them. I impute no negligence to anyone, but of one thing I am sure, and that is that more revaccinations would be done amongst adults if the dread—for which there are some good grounds—of "bad arms" could be successfully met.

I am, Sir, yours faithfully,

A. B. DUNNE, M.B. Camb., D.P.H., &c.

Doncaster, Feb. 26th, 1924.

THE TRAINING OF THE OPHTHALMIC SURGEON.

To the Editor of THE LANCET.

SIR,—Ophthalmology is one of the most strictly scientific parts of medicine, being founded largely on physics, physiology, and pathology. Before a man begins practice as an ophthalmic surgeon he should have a fairly extensive training in physical and physiological laboratories. Up to the present time the General Medical Council, notwithstanding many a hint, has made no provision for the training and registration of ophthalmic practitioners. I put it bluntly when I say that any person who is rich enough to buy a case of trial lenses and test types can call himself an eye specialist. I know we have plenty of men in the United Kingdom who are worthy successors of Bowman and Nettleship, but there is nothing to distinguish them from the considerable number of practitioners who have never been either in a physical or physiological laboratory. The issues at stake are so important that the eye specialist should be trained just as extensively as is the specialist in public health.

I cannot attach much weight to the diplomas at present given in the United Kingdom. The course of study for these diplomas is not at all adequate. As an extreme example of what is possible: an eye specialist recently informed his readers that Maddox had announced the fact that the hypotenuse of a right-angled triangle is equal to the square root of the sum of the squares of the other two sides, and in the same contribution he said that Maddox had found that the angle between any two straight lines is given by the sine of the angle. Now a man who does not know the forty-seventh proposition of the first book of Euclid when he sees it and who does not know the trigonometrical functions of an ordinary right-angled triangle has never been a student in a physical laboratory and is quite incompetent to read the special parts of ophthalmic literature.

The danger that I see is this. There are a large number of opticians clamouring to be recog-

nised as eye specialists of a sort. Instead of having two months of study, as is required for some of the ophthalmic diplomas, these men have had perhaps two years, devoted almost entirely to the very important subject of the testing of refraction errors and of muscular errors. Personally I am opposed to registering these men as qualified ophthalmic practitioners. They certainly have received a better training in a very important sphere of ophthalmology than a good number of persons who are practising as ophthalmologists. The opticians referred to are agitating for registration. Ophthalmic surgeons may reasonably say that these opticians are not qualified; nor are they. But it is open to them to reply that there is no guarantee that ophthalmic surgeons are properly qualified. Probably these opticians have a much better training in the physics of vision than have a fair number of the eye specialists, and my objection to their being regarded as qualified to practise arises from the fact that muscular testing and refraction testing form only a small part of ophthalmic work. It does not take in the ordinary diseases of the eye, nor does it take in the important relationships between ophthalmology and neurology, nor the surgical work.

Personally I would regard any licensing of opticians to practise any part of ophthalmology as a public danger. At the same time I do acknowledge that a number of these opticians have, so far as theory is concerned, an excellent knowledge of optical work. There is a grave risk of their being recognised as ophthalmic practitioners, and so long as the General Medical Council tolerates the present state of affairs it seems to me that the opticians have a good case.

I am, Sir, yours faithfully,

Glasgow, Feb. 27th, 1924. FREELAND FERGUS.

DOCTORS AND ADVERTISING.

To the Editor of THE LANCET.

SIR,—Dr. Harold Spence's courageous, sane, practical, and humorous article under the above heading appearing in your issue of Feb. 23rd must, I think, express the opinion of the majority of medical practitioners. He satirises the convention which permits advertising through bulletins or news paragraphs, whilst discountenancing press references to medical men which appear to have no professional advertising value, and he claims a medical man's complete and unassailable right both legally and morally to secure publicity in certain ways, provided always that he is careful to preserve the rules of professional honour.

Dr. Spence draws attention to the unfortunate position in which the practitioner interested in the treatment of venereal disease finds himself, owing to the competition with free venereal clinics, where the financial position of the patient attending is not considered, and where the clinic is enabled to obtain that publicity which is denied the private practitioner.

The point which I wish to emphasise, however, is that the health and efficient medical service of the public is more important even than professional dignity. In the majority of diseases if a member of the public desires to have the opinion or treatment of a medical man especially experienced in the disease from which he suffers, he usually either follows the advice of his family doctor or of his friends in regard to the medical man he should consult. As regards venereal disease, however, the case is different, and he frequently carefully avoids his family doctor and is ashamed to ask his friends' advice. The usual reference works prove of little use to him as he does not know any name to look up, and does not feel inclined to wade through a long directory until he finds a name of a practitioner who appears to devote himself to this class of work. In many cases, therefore, he applies for information either to a venereal clinic or to a chemist as to whom he should consult, and it appears natural to presume that the advice tendered by institution or chemist would be influenced by personal association, and would not necessarily be in the best interests of the patient.

What seems to be desirable from the public point of view is such publicity as would be obtained in a carefully drawn-up register, copies of which would be easily accessible to the public, containing the various diseases or branches of medicine under different headings, and supplying details of practitioners claiming special experience in regard to such diseases. This register or directory could be drawn up by some competent authority and would contain the data, such as hospital or clinic appointments, publications, &c., on which the public would be able to form an opinion and arrive at a conclusion as to whom to consult. If some such register were widely advertised it would be a means of protecting the public and securing adequate publicity without advertisement for medical practitioners who have had special experience in certain branches of the profession.

Some of the existing books of reference could easily be adapted by adding a section in which practitioners' names were grouped under the diseases or branches of the profession in which they were interested, and their records could then be looked up in the preceding alphabetically arranged portion.

I am, Sir, yours faithfully,

H. WANSEY BAYLY.

Harley-street, W., Feb. 23rd, 1924.

LEPROSY: A SELF-HEALING DISEASE.

To the Editor of THE LANCET.

SIR,—In 1891 Dr. Kaurin showed me over the Leper Hospital at Molde, Norway, and drew my special attention to an apparently perfectly healthy young girl of about 23. He assured me that when she was first under his care she was a typical leper, but for some months all signs of the disease had left her, so that at the present time no one could have suspected that she had ever been a leper. I do not know the sequel, for on my next visit to Molde four years later I found, to my great regret, that the Leper Hospital there was closed.

I am, Sir, yours faithfully,

London, N.W., Feb. 23rd, 1924. LEONARD J. KIDD.

THE EXPLOITATION OF NURSES.

To the Editor of THE LANCET.

SIR,—The Chairman of the Finance Committee, General Nursing Council, seems satisfied that all is for the best in the best of all possible worlds for the nursing profession and the public. He rightly pleads that a fee of five guineas for *two* examinations is not excessive, but this does not alter the fact that every candidate will have to pay five guineas, and some will have to pay more if they fail to pass either examination on one or more occasions.

I am anxious to know what sort of standard the G.N.C. proposes to adopt. Will it be so high as to ensure the failure of a considerable number of candidates, and act as a deterrent to girls thinking of becoming nurses? Or will it be so low as to render the pretentious syllabus ludicrous and the examination a farce? Even a moderate percentage of rejections will have a tragical effect and a very low one will be comical.

My suggestion that the G.N.C. is anxious to obtain better and more expensive accommodation, like my other criticisms, is ignored. I note that a paragraph in the *Nursing Times*, Feb. 9th, states that the Council recently "turned down the house in Portland-place, evidently an attractive proposition." And there is no attempt to controvert my point that hard work for three years on a minimum salary and heavy fees for examination, with the possibility of rejection, will cause a deficiency in the supply of nurses. Certainly the policy of registration has not improved the quantity or quality of the girls entering our hospitals for training.

Seeing that registration is not compulsory and that the passing of a State examination is not essential to becoming a competent nurse, the G.N.C. is ill-advised

n creating the impression that their syllabus and xaminations will render registration difficult of ttainment. At present there are many partially rained nurses, some excellent, in private work. If hose now in training refuse to pay for the risks of xamination and are content with a certificate of three ears' full training at a general hospital, it is probable hat they would have little difficulty in obtaining work r would be inferior to registered nurses. I have heard uch grumbling from qualified and unqualified nurses n the lines of my former letter, but those who know he nursing world will understand the reluctance to xpress their views in print. As for their ability to xercise any influence by voting for representatives n the G.N.C., most of them know as little about ursing politics as about general politics. Even those ho voted in favour of registration were generally gnorant of what they were doing, signing because the atron or sister of the ward told them to. I do not now whether the G.N.C. publishes an audited balance-heet. Certainly registered nurses do not receive a opy and are in complete ignorance of the expenditure n this wretched farce, as well as knowing nothing of he general policy of their Council.

I am, Sir, yours faithfully,

Park-street, W., Feb. 25th, 1924. EDMUND CAUTLEY.

VARIATIONS IN SUSCEPTIBILITY TO INSULIN.

To the Editor of THE LANCET.

SIR,—In the course of an experimental research pon insulin, on which we have been engaged for some ime, we have found that the colour of the animals vith which we experimented had a very material nfluence upon their susceptibility, albino rabbits and nice being able to withstand without apparent harm n amount of the same preparation which proved apidly fatal to naturally coloured or piebald animals f a similar weight, whereas black rabbits and mice uickly succumbed to a dose from which naturally oloured or piebald animals recovered. The reason for his peculiarity is being investigated, and we hope hortly to publish our results in detail. Apart from heir theoretical interest these observations are of onsiderable importance seeing that the present nethod of standardising insulin is based solely upon ts physiological effects upon rabbits and mice. It is bvious that unless animals of the same colouring, as well as of standard weight and condition, are employed here may be considerable variation in the potency of he unit. It seems possible also that the different usceptibility of albino and self-coloured rabbits to nsulin may account for the apparent loss of potency f preparations sent from this country to the tropics. It has been stated, for instance, that four times the mount of insulin which reduced the blood-sugar of a abbit in England to 0·042 per cent. only reduced the lood-sugar to 0·062 per cent. in India,[1] but as we nderstand that the Himalayan rabbit with which the xperiments were probably carried out in India is a ink-eyed partial albino, the difference in these esults may have been due to that fact.

We are, Sir, yours faithfully,

P. J. CAMMIDGE.
London, Feb. 21st, 1924. H. A. H. HOWARD.

TREATMENT OF LIVER ABSCESS BY ASPIRATION.

To the Editor of THE LANCET.

SIR,—Dr. A. R. Neligan, in his article on this subject in your issue of Dec. 29th, 1923, refers to a paper of mine read before the Medical Section of the Asiatic Society of Bengal and published in the *Indian Medical Gazette* of March, 1914. As his reference to my paper gives a wrong impression, I shall be glad if you will permit me to correct it. In the first place, the series of 101 cases were all my personal ones, operated on in many different hospitals, not all in Bengal, and the case-histories were taken from my private case-book, not compiled from old hospital notes, thus ensuring a greater accuracy. Secondly, my earlier cases, beginning in 1900, were treated by incision and drainage, and these were followed by treatment by aspiration and the injection of quinine in the cavity, and the last set of cases were treated by aspiration alone, followed by the injection of emetine hypodermically immediately the aspiration was finished; the results of this last method being immeasurably superior to the old operation. I have therefore been a strong advocate of aspiration combined with the administration of emetine for many years. The subject being apparently still of some interest, I propose to publish shortly another series of 63 cases.

I am, Sir, yours faithfully,

E. OWEN THURSTON,
Lieutenant-Colonel, I.M.S.

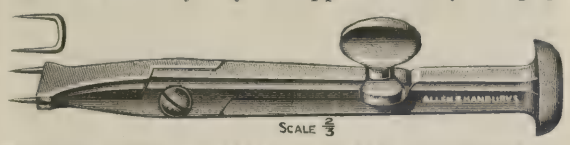
Chinsurah, Bengal, Jan. 29th, 1924.

[1] THE LANCET, Jan. 12th, 1924, p. 101.

STAPLE HOLDERS FOR ROUX'S OPERATION.

To the Editor of THE LANCET.

SIR,—I am interested in the description of a staple holder for use in the Roux operation for femoral hernia by Mr. A. MacLennan in your issue of Jan. 26th. Thirteen years ago a description of a similar instrument devised by myself appeared in your pages



(1911, ii., 1020). I think that this instrument has certain advantages over that proposed by Mr. MacLennan. The scissor form of the clamp ensures a firm grip of the staple and allows of its ready release after it has been hammered into place. The instrument was made for me by Messrs. Allen and Hanburys. I am, Sir, yours faithfully,

Harley-street, W., Feb. 14th, 1924. C. MAX PAGE.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. E. W. Gandy is placed on retd. list with the rank of Surg. Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj.-Gen. Sir David Bruce, ret. pay, late R.A.M.C., is appointed Col. Comdt., vice Maj.-Gen. Sir Owen E. P. Lloyd, ret. pay, late R.A.M.C.

The undermentioned to be Lts. (on prob.): C. R. Christian, J. Huston, E. G. Dalziel, C. W. Greenaway, R. J. Rosie, M. A. Graham-Yooll, and L. F. O'Shaughnessy, from R.A.M.C., T.A. Gen. List.

The undermentioned Lts. are secd.: M. A. Graham-Yooll and L. F. O'Shaughnessy.

MILITIA.

Capt. J. A. Charles relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. F. J. Whitelaw (late R.A.M.C.) to be Capt.

Capt. G. B. Brand to be Maj. (Prov.).

Supernumerary for service with the O.T.C.—Maj. A. E. Webb-Johnson ceases to be empld. with the London University Contingent, O.T.C.

Capt. (Local Maj.) T. B. Layton resigns his commn. and is granted the rank of Lt.-Col. with permission to wear the prescribed uniform.

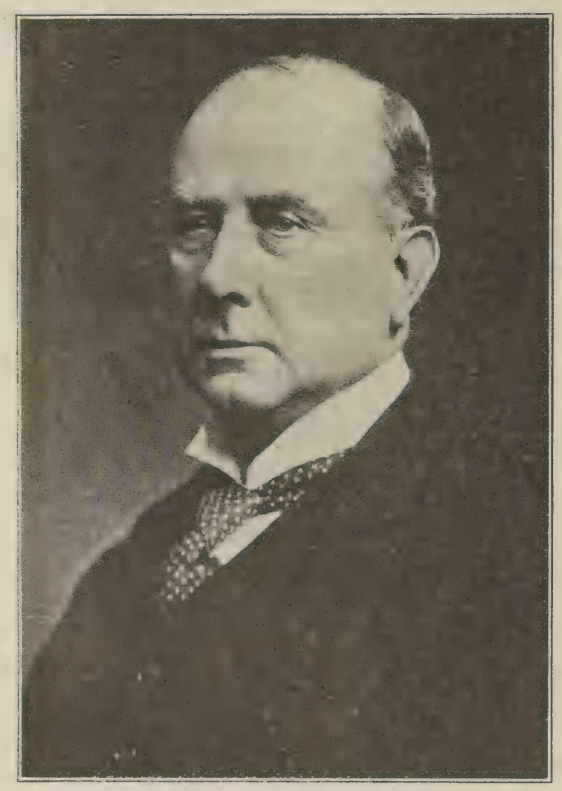
HONG-KONG UNIVERSITY. — The Rockefeller Foundation has allocated the sum of $250,000 to the University for the chairs of medicine and surgery. Hong-Kong University was founded in March, 1911, for British subjects, and degrees in arts, medicine, and engineering are conferred.

Obituary.

SIR MALCOLM ALEXANDER MORRIS, K.C.V.O., F.R.C.S. EDIN.

THE sudden death of Sir Malcolm Morris on Feb. 19th, at Bordighera, marks the passing of a man who, for upwards of half a century, fostered the progress of medical science in its widest aspects.

The fifteenth child and youngest son of Mr. John Carnac Morris, of the Madras Civil Service, he was born in Mansfield-street, Portland-place, in 1849. His medical student days were spent at St. Mary's Hospital, where, after qualifying M.R.C.S. at the age of 21, he served a year as house surgeon before taking up general practice in Yorkshire. He visited Berlin and Vienna, continued medical studies, and at the latter centre became interested in dermatology. On his return to England he was appointed clinical



[*Photo by Elliott and Fry.*

SIR MALCOLM MORRIS.

assistant at the Blackfriars Hospital for Diseases of the Skin, and later lecturer on dermatology at his old medical school attached to St. Mary's Hospital. He took the F.R.C.S. Edin. diploma in 1880, and in the same year became definitely surgeon-in-charge of the skin department at the hospital, and his work there for the next 20 years, both as a medical man and as an author and a public servant, undoubtedly served the institution well.

The study of dermatology at St. Mary's Hospital, and also at the Seamen's Hospital, Greenwich, where he was dermatologist, focused his attention almost from the first on the two great scourges of tuberculosis and syphilis, and during the full half century in which they claimed his attention and practical skill he saw the foundation laid for their eradication. Clinical and pathological work had been profuse in respect to both diseases, but the ætiology was unknown and the therapeutics were directed only to symptoms. The immense possibilities of Koch's discovery of the tubercle bacillus in 1882 at once appealed to Morris. No sooner had the discovery been proclaimed than he journeyed to Berlin and was privileged to witness the first demonstration by the great bacteriologist. One of the foremost amongst the supporters of Koch's theories in England, in 1899 he represented the National Association for the Prevention of Tuberculosis at the Congress in Berlin, and in 1901 he was secretary-general of the British Congress on Tuberculosis, the occasion on which Koch expressed his much criticised and since discredited views on the mutual relations of human and bovine tubercle bacilli. In the same year he visited the United States and delivered the Lane lectures in San Francisco.

The great attack on tuberculosis by the medical world was paralleled a decade later by the advance made against syphilis. In 1905 came the discovery of the spirochætes and following this discovery the modern treatment of syphilis. In 1913 Sir Malcolm Morris, realising the apathy in the public mind towards the disease and the general conspiracy of silence on the whole question, put forward a powerful appeal for the appointment of a Royal Commission on Venereal Diseases, and saw his proposals realised in the autumn of that year. He served on the Commission for the three years of its existence, and when the National Council for Combating Venereal Diseases was established in 1914, Morris was elected one of the vice-presidents. Here his views on prophylaxis were strenuously opposed to the indiscriminate dissemination of self-disinfection as a reliable measure of protection. In 1917 he published "The Nation's Health," as an effort directed to the stamping out of venereal disease, and written for the guidance of lay authorities.

As a dermatologist he enjoyed honorary or corresponding membership in many French, Italian, and American societies for the study of this subject, and was a past president of the Dermatological Section of the Royal Society of Medicine. In 1893 he served the office of president of the Harveian Society of London. He was also a member of the Committee of the Radium Institute. In 1894 he published a manual on "Diseases of the Skin," in which he gave in outline the principles and practice of dermatology. The work was considered as one of the best of the smaller text-books of the day, particularly in its practical aspects, although the author differed from current medical opinion on one or two points. A sixth edition of the book, considerably enlarged, was issued in 1917, a proof of the ever-growing value of Morris's contributions to his subject. He was one of the earliest to employ the Finsen light in the treatment of skin affections in this country, and in 1907, along with Dr. Ernest Dore, he gave a concise description of the practice of radiant method in "Light and X Ray Treatment of Skin Diseases." In 1908 the honour of knighthood was conferred on him, an honour which Sir Malcolm Morris chose to regard as a recognition of the position gained for dermatology as a branch of scientific medical study.

His activities and interest in other branches of public health were manifold. In 1917 he was elected president of the Institute of Hygiene. He was a fellow of the Royal Sanitary Institute, and chairman of the Federation of Medical and Allied Services. He was also a member of the International Council on Leprosy. In succession to his friend, Sir Henry Thompson, he was an advocate of cremation, and long served on the Council of the Cremation Society of Great Britain. In 1919 Morris published "The Story of English Public Health," a volume of an English Public Health Series, of which he was editor. In this book he gave a short history of the growth of the public health movement from the work of Edwin Chadwick, which culminated in the passing of the Public Health Act of 1848, down to the establishment of the Ministry of Health.

Sir Malcolm Morris, as writer and speaker, possessed great energy and facility of expression, and his interest in literature, in particular medical literature,

ook a practical form. At an early stage of his career e enlisted the interests of Messrs. Cassell and Co. ı medical publications, and in 1883 the firm published nder his editorship "The Book of Health," to be ollowed by two series of manuals, the one dealing ith physiology, pathology, and comparative anatomy, he other with clinical subjects, both of which met ith success. In 1886 he was co-editor with Dr. linis Hays, of Philadelphia, of the *International ournal of the Medical Sciences*, and from 1895 to 1902 e took over the editorship of the *Practitioner*, which e conducted with great journalistic ability. Later in fe he became a director of Cassells, Ltd.

In addition to his work for the *Practitioner* many f his contributions appeared in THE LANCET and ther medical journals. In 1921 he edited, in associa- on with Prof. F. Langmead and Dr. Gordon Holmes, "Dictionary of Practical Medicine," designed for he working practitioner, which contained in three olumes a symposium of the most modern advances ı medical knowledge.

Sir Malcolm Morris married Fanny, daughter of homas Cox, of Dorchester, Oxon, and in 1922 his olden wedding was celebrated by a congratulatory ıncheon at which a large group of personal and rofessional friends were present. On this occasion e told[1] of his early struggles in his attempt to make ood in London, and asserted that the secret of keeping oung was to have, to cultivate, and to preserve ıterest in public questions when that interest was irected towards the betterment of fellow men. He ved consistently up to his recipe.

ALEXANDER CHARLES O'SULLIVAN, M.B. DUB.

THE death, in his sixty-seventh year, of Dr. A. C.)'Sullivan, professor of pathology in the University f Dublin, which took place on Feb. 18th, is a serious)low to the cause of pathological research in Dublin. Ie was a remarkable and many-sided man, as his cademic career amply demonstrates. The elder son f the Rev. Denis O'Sullivan, rector of Macroom, o. Cork, he entered Trinity College, Dublin, in 1876 rom Dungannon Royal School. When he came up to he University he was equally proficient in classics and ı mathematics, but during his undergraduate course ecided to take up mathematics and philosophy for is degree. Having obtained a mathematical scholarship ı 1879 he graduated with the highest honours in 1881. Ie was a notable athlete, being a member of the Rugby ifteen and of the University eight. In later life he pent his holidays sailing and was a yachtsman of no ıean skill. Shortly after graduating he set himself to ead for Fellowship, which he won in 1886. In those ays the old system of examination for Fellowship ı all sorts of subjects was still in being, and O'Sullivan nswered brilliantly in mathematics and with distinc- ion in classics, an unusual combination. Acting on he advice of Dr. Samuel Haughton he decided to take ıp the medical profession, and having gone through he medical school while acting as a tutor Fellow, he ook his medical degrees and, obtaining leave from the)ollege authorities, he spent a couple of years at rankfurt and Vienna in pathological research. The chool of Pathology was created shortly after his)'Sullivan was appointed lecturer. It is not too ıuch to say O'Sullivan's appointment was the most mportant event in the modern history of the school. Ie brought a new spirit into the relations of teacher nd student. Inspired by his old teacher, Dr. John urser, then professor of physiology, he was almost ntirely responsible for the organisation of the new chool and for the repute in which it was held by he younger Dublin physicians. O'Sullivan was ı due course elected a Fellow of the Royal ollege of Physicians of Ireland, and he read many hort papers on pathological subjects before the cademy of Medicine and the Biological Club. areless of personal distinction, he did not publish his work, as his friends often entreated him to do, in the larger pathological journals, but his colleagues had the highest respect for his knowledge and his judgment in regard to pathological problems. He acted as consulting pathologist to one or two of the leading Dublin hospitals.

When the war broke out he took his full share, being appointed Major in the R.A.M.C., and proceeded to Malta, where in 1915–16 he did valuable work on the pathological side in the Army hospitals. He attained the rank of Lieut.-Colonel and was mentioned in despatches in 1917. He was afterwards consulting pathologist to the Irish Command. Recently his lectureship in pathology was constituted a full professorship. He fulfilled the duties of registrar to the School of Physic for the past five years, where his long acquaintance with the several aspects of college life made him specially valuable as a guide to and supporter of the traditions of the University which he loved and served so well.

A colleague at Trinity College, "J. H. B.," writes of him: "All through his working years O'Sullivan discharged to the full his academic duties as a Fellow, and he lectured and examined in arts as well as in pathology to the surprise of visitors to the University who were unacquainted with the old traditions of the College in virtue of which a Fellow was supposed to be able to turn his hand to anything. This antiquated tradition is now rapidly disappearing, but O'Sullivan was a remarkable illustration of its value in the case of really exceptional men. A man of science in the first place, he had wide classical culture, and to the end of his days he pursued the later developments of pure mathematics in his leisure hours. As the fruit of these labours he made several contributions to the mathematical discussions of the Royal Irish Academy. He was one of the most notable figures at Trinity College, and probably there was no one among the teaching staff who was regarded with so much affection by his many pupils and also by his colleagues."

Prof. O'Sullivan married Constance, daughter of the late Canon Whelan, and his widow, with two sons and two daughters, survives him.

ROBERT THOMSON, M.D., M.CH. RUI.

THE death occurred of Dr. R. Thomson, of Margate, surgeon and medical superintendent to the Margate Cottage Hospital, on Feb. 13th, in his sixty-third year. Dr. Thomson graduated M.A. of Queen's University, Belfast, in 1881, where, four years later, he took the medical degree of M.D., M.Ch., qualifying at the same time as L.M.R.C.P.I. In 1887 he entered general practice in Margate, first as assistant and shortly afterwards as a partner of the late Dr. Edward White. From his earliest years as a practitioner he came into touch with the clubs and friendly societies of the district, where by his able and unselfish work he won for himself a position of esteem and respect. He was appointed in 1897 to the surgical staff of the Margate Cottage Hospital, of which he later became medical superintendent. In 1915, in recognition of long years of devoted work, he was elected president, a position which he filled with ability and credit for a period of three years. During the war he was surgeon at Wanstead Military Hospital from 1914 until October, 1917. In 1922 ill-health necessitated the curtailment of his activities, but latterly he had recovered considerably, and his death from pneumonia came as a shock to his many friends.

A colleague, "A. G.-S.," sends the following appreciation: "For many years I had the honour of being closely associated with Dr. Thomson in work, both civil and military, and the mortality percentage with him was so low as to make one marvel. And he did a large amount of operating work, chiefly abdominal. As his anæsthetist for some 12 years I had the opportunity of witnessing his skill and extraordinary care in surgical procedures. Although in his later years Thomson's work was chiefly surgical, yet he was a very fine

[1] THE LANCET, 1922, ii., 207.

type of general practitioner. In medicine his opinion was sound, in gynæcology and midwifery he excelled, and in general and abdominal surgery he had few equals. Reserved as he was, few knew him intimately. But to those few his best characteristics were ever present—generosity, sympathy, a scrupulous care for the feelings of others, and an unswerving sense of friendship. Thomson solved many a difficult problem for a junior colleague; to the younger men he did all he could to help and advise, and by his patients he was revered and respected to a most unusual extent. Two years ago he was afflicted with severe prostatic trouble; just as he was getting well enough for the operation he so ardently desired he had a cerebral hæmorrhage. For 18 months he was condemned to a life of invalidism, and during this long time one never heard from him a single word of complaint. A broncho-pneumonia of a very toxic type ended the life of one who, delicate in physique, had a strength of character and courage under difficulties rarely seen."

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, FEB. 19TH.

Free Treatment of Venereal Disease.

Mr. SOMERVILLE HASTINGS asked the Minister of Health if he could give any estimate as to the result the provision of free treatment by the State had had on the incidence of venereal disease; and whether, if the result had been good, he intended to adopt similar methods for free treatment for other diseases.—Mr. WHEATLEY said: The information in my possession tends to show that the incidence of these diseases is declining, and that the provision of free treatment has undoubtedly contributed to that result. As my hon. friend is aware, there are certain features of these diseases which differentiate them from other communicable maladies, and which render the provision of free treatment especially desirable in the interests of the community. I could not undertake, within the limits of question and answer, to discuss the expediency of adopting similar methods for other diseases.

Hospital Accommodation.

Mr. SOMERVILLE HASTINGS asked the Minister of Health whether he could give the number of persons at present requiring treatment in the hospitals of London and unable to obtain it through lack of beds; and what he proposed to do to provide the necessary hospital accommodation for such people.—Mr. WHEATLEY said: No information is at present available, and considerable inquiry would be necessary to obtain even an approximate estimate. I propose, however, to ask the Voluntary Hospitals Commission to report on the extent of the additional accommodation required and the best means of providing it. The hon. Member is doubtless aware that provision of hospital beds is not within my statutory powers.

WEDNESDAY, FEB. 20TH.

Royal Commission on National Insurance Service.

Sir KINGSLEY WOOD asked the Prime Minister whether he proposed to advise the setting up of a Royal Commission to investigate the medical service under the National Insurance Act and kindred matters.—Lieut.-Colonel FREMANTLE asked the Minister of Health whether, seeing that a court of inquiry had recently estimated the value of the medical service under the national health insurance system, he would advise the appointment of a Royal Commission, as promised by his predecessor, to investigate the administration of national health insurance.—Mr. WHEATLEY (Minister of Health) replied: The Government propose to advise the setting up of a Royal Commission as soon as arrangements can conveniently be made to inquire into and make recommendations as to the whole system of national health insurance.

Sir KINGSLEY WOOD asked the Minister of Health the steps he proposed to take in connexion with the recommendation of the court of inquiry into the remuneration of medical practitioners on the panel.—Mr. WHEATLEY replied: The question of introducing the legislation required to give effect to the recommendations of the court of inquiry is now under consideration, and I am not yet in a position to make any statement.

Leprosy in the United Kingdom.

Mr. BECKER asked the Minister of Health the number of cases of leprosy notified in the United Kingdom during the last annual period; how many persons in the United Kingdom are suffering from leprosy; and for information as to the efficiency of the new cure for leprosy.—Mr. WHEATLEY replied: Leprosy is not compulsorily notifiable in this country, and the information available as to the number of persons suffering from this disease is only approximate. It is, however, known that the total number of cases in this country is very small, and during the past 25 years official records show that only 24 cases have been imported. As regards the last part of the question, the Secretary of State for India tells me that favourable reports are being received from that country regarding new methods of treatment, but it is not yet possible to say what proportion of cases can be cured.

The Influenza Outbreak.

Sir KINGSLEY WOOD asked the Minister of Health whether there was any indication of a falling off in the extent of the outbreak of influenza, and whether he was taking any special steps to deal with the outbreak.—Mr. WHEATLEY replied: I am advised that it is not possible to predict with certainty the course of the present outbreak of influenza, but there are indications that its maximum incidence will be reached shortly. The disease appears generally to be of a mild type, and it has not been considered necessary to take any special emergency measures.

General Nursing Council Rules.

Dr. CHAPPLE asked the Minister of Health whether he was aware that applicants for registration under the Nurses Registration Act, 1919, amended by a rule passed in July, 1923, had been rejected on the ground that their applications should have been lodged before July 14th, 1923; and whether he would take the opinion of the law officers of the Crown as to the legality of this action of the General Nursing Council.—Mr. WHEATLEY replied: I am advised that the Council have no power to admit applicants for registration as existing nurses after July 14th, 1923, and I see no necessity for consulting the law officers of the Crown.

Dr. CHAPPLE asked the Minister of Health whether he had evidence that many hospital-trained nurses had failed to register under the Nurses' Registration Act, 1919, because of neglect to send in applications within the period prescribed by the Act; and, if so, would he consider an amending Bill extending this period.—Mr. WHEATLEY replied: There is no evidence that any appreciable number of trained nurses who desired to be registered failed to apply during the two years' period allowed by the Act; and I see no necessity for amending legislation.

Dried Milk Regulations.

Mr. LAMB asked the Minister of Health the reasons which led his department to modify and postpone the operation of the Public Health (Dried Milk) Regulations; what was the nature of the objections to these regulations that were regarded by his department as confidential; and why the representative organisation of dairy farmers in England and Wales was not permitted to learn the nature of the objections taken to the original draft regulations.—Mr. WHEATLEY replied: The Public Health (Dried Milk) Regulations were published in draft form in July last with a view to eliciting any representations which might be made by parties concerned for consideration in my department. A number of representations dealing with points of detail were made on behalf of manufacturers and traders, and my predecessor was satisfied that it was possible to meet some of them without prejudicing the interests of the consuming public, and that it would be impracticable to bring the regulations into operation at the date originally suggested. I am not aware whether the representations made were intended to be regarded as confidential, but it was not considered that there was any ground for communicating representations submitted for the consideration of the department to other bodies.

Condensed Milk Regulations.

Mr. LAMB asked the Minister of Health whether he was aware that the customs authorities had no power to hold up consignments of imported condensed milk, the labelling of which did not conform to the Public Health (Condensed Milk) Regulations; and whether, since such improperly labelled milk might reach the consumer before the local authority concerned was in a position to take action, what steps he proposed to take in the matter to safeguard the public health.—Mr. WHEATLEY replied: The answer to the first part of the question is in the affirmative. The ultimate procedure for the enforcement of the regulations is by prosecution, involving the liability to a substantial fine, and I see no reason to suppose that the arrangements adopted for enforcement will prove to be inadequate to secure the object in view.

Deaths from Infantile Paralysis.

Mr. BECKER asked the Minister of Health the number of ildren under the age of 7 years who died of infantile paralysis ring the last 12 months; has his department any evidence owing that the high mortality amongst young children is e to the drinking of impure milk; and what steps does he opose to take to ensure a pure milk-supply.—Mr. HEATLEY replied: I can best answer the first part of the estion by giving the following provisional figures for aths during 1923 of children under 7 years of age, registered due to poliomyelitis and polioencephalitis: Polio-yelitis, 46; polioencephalitis, 20. The answer to the cond part of the question is in the negative.

Salaries of Health Visitors.

Mr. JOHN HARRIS asked the Minister of Health whether eing that the London District Council proposed that the laries for inspectors and health visitors in London should e for sanitary inspectors £190 per annum, rising to £300 er annum, and health visitors £150, rising to £250 per num, that his predecessor refused to agree to this scale, nd that the subject was left in abeyance, what action His ajesty's Government proposed to take in the matter.—r. WHEATLEY replied: I have arranged to discuss the atter with representatives of the London District Council.

Spirochætosis among Miners.

Mr. CLARKE asked the Minister of Health if he was aware nat a number of miners employed in East Lothian collieries ad been seized with a disease, diagnosed by a professor in the dinburgh Royal Infirmary as spirochætosis, a form of oison due to the presence of rats in the workings; and nat all of them were seriously ill and several had died from its ffects; and what steps was he taking to deal with the isease and the cause, which had created widespread alarm in ne district.—Mr. STEWART (Under-Secretary of Health for cotland) replied: The Scottish Board of Health are aware nat an outbreak of infective jaundice has occurred in ast and mid-Lothian; that the majority of those affected re miners; that within a year there have been 14 known ases, four of which resulted fatally. The bodies of three nts have been proved to be affected by the spirochætosis tero-hæmorrhagica. By regulations of the Board, dated eb. 4th, the disease has been made notifiable in the city of dinburgh and in East and mid-Lothian, including the urghs in these counties. The local authorities of the reas affected have the matter under observation, and the oard of Health are in communication with the Board of griculture and the Mines Department Inspectorate.

The Tuberculosis Order, 1914.

Sir HENRY WEBB asked the Minister of Health whether he ad reconsidered the decision of his predecessor as to the evival of the Tuberculosis Order of 1914; and, if so, when ne order would be put into operation.—Mr. BUXTON Minister of Agriculture) replied: I may explain that the uestion as to whether it is practicable to put into operation t the present time the Tuberculosis Order of 1914 is now nder consideration. I hope to be able to come to a decision n the matter at an early date.

Panel Patients in Public Institutions.

Mr. THURTLE asked the Minister of Health whether he ould take steps to amend the existing National Health nsurance Acts in such a way as to provide that when an nsured person was admitted to a public institution for reatment the panel practitioner responsible for the case hould be subjected to a reduction of his panel fee in respect f his failure to supply medical attention in accordance with is contract.—Mr. WHEATLEY replied: When an insured erson is under treatment in an institution with a selected nedical staff, which is not open to all general practitioners in he area, the obligation of the insurance practitioner to rovide treatment ceases for the time being. The hon. Member is under a misapprehension in suggesting that in uch cases there has been any failure on the practitioner's art to fulfil his contract, and I see no ground for reducing he capitation fee, in fixing which the limits of the obligation n regard to institutional treatment were taken into account.

Boards of Guardians and Insured Persons.

Mr. THURTLE asked the Minister of Health whether he as aware that, when persons insured under the National Health Insurance Acts were admitted to Poor-law hospitals or treatment, the boards of guardians concerned were precluded from receiving any benefits under these Acts in respect of the treatment so afforded; and whether he would take steps to have this restriction removed.—Mr. WHEATLEY replied: Boards of guardians have the ordinary powers of recovery of expenses incurred in providing treatment in a Poor-law hospital to a person insured under the National Health Insurance Acts, as in the case of all other persons for whom such treatment is provided. I do not think it either necessary or desirable that they should have any additional powers of recovery in the case of insured persons, and I would remind the hon. Member that any benefits to which such persons may be entitled under the National Health Insurance Acts are given in return for contributions compulsorily payable by themselves and their employers.

Houses Unfit for Habitation.

Mr. CECIL WILSON asked the Minister of Health the number of occupied houses which medical officers had reported as at present unfit for human habitation; how many persons were living in such houses; and the death-rate in regard to such houses.—Mr. WHEATLEY replied: According to statistics obtained from the reports of medical officers of health for the year 1922, 15,869 houses in England and Wales were found to be unfit for human habitation. Particulars are not available as to the number of persons living in these houses, or the death-rate in regard to such houses.

Suicide Statistics.

Mr. WRIGHT asked the Minister of Health if he could give the returns from the reports of the Registrar-General of the number of suicides per million of the population for each quinquennial period 1896–1900 to 1916–1920 inclusive.—Mr. WHEATLEY replied: The required figures for England and Wales are as follows:—

Period.	Rate per million population.
1896–1900	89
1901–1905	101
1906–1910	102
1911–1915	95
1916–1920	79

The figures given in respect of the years 1915–1918 relate only to civilian deaths and population.

THURSDAY, FEB. 21ST.

Ex-Service Men and Mental Disease.

Mr. PIELOU asked the Minister of Pensions if it was his intention to be responsible for the some 600 ex-Service men who were suffering from mental trouble who were at the moment under the care of the guardians.—Mr. F. O. ROBERTS replied: I assume that the hon. Member is referring to those ex-Service men for whose maintenance the responsibility of my department came to an end on Sept. 30th, 1922, under the expressed terms of Article 7 (2) of the Royal Warrant. The Government have decided to meet the charge for the maintenance from April 1st next of these men by means of a special exchequer grant which will not, however, fall on the vote of my department. I understand that Parliament will be asked to make the necessary provision in the votes of the Board of Control for England and Wales and General Board of Control for Scotland.

Pensions Medical Staff.

Mr. HOGGE asked the Minister of Pensions whether a large reduction of the medical staff of the Ministry was in contemplation; if so, on whose recommendation such reduction would be made; and whether he would consider withholding such reduction until the proposed departmental committee had considered the same and reported.—Mr. F. O. ROBERTS replied: Owing to the inevitable reduction of the work of my department, there is necessarily a corresponding decrease in the medical staff required. I am not contemplating any special reductions in the medical staff.

Lieut.-Colonel WATTS-MORGAN asked the Minister of Pensions the number of medical men employed at the Ministry headquarters in all grades in December, 1923; how many were over 60 years of age; and how many were engaged actually in the various theatres of war on active service.—Mr. F. O. ROBERTS replied: The number of medical men employed at Ministry headquarters on Dec. 31st last in all grades was 31, of whom three are over 60 years of age; 29 of these officers served during the war, 23 of them having served overseas.

The Use of Hashish.

Mr. GILBERT asked the Under-Secretary of State for the Home Department whether, seeing that hashish was not included in the list of dangerous drugs which were under restriction of importation into this country, he had any information of the use of this drug in certain seaport towns; and whether he proposed to take any steps to add this drug to the list of dangerous drugs and under the same restrictions as apply to them.—Mr. RHYS DAVIES replied: I have no information to show that indulgence in the use of hashish is anything but rare in this country, though it is possible it is practised to a certain extent among oriental seamen visiting our ports. Hashish is not one of the drugs to which the International Opium Convention of 1912 applies, though the Hague Conference recommended that its use should be investigated. Any proposal for the extension to hashish of the restrictions relating to the drugs included in the Convention would have to be considered from the international

standpoint, and I understand that the League of Nations, which by the Treaties of Peace is entrusted with the general supervision over the traffic in dangerous drugs, has not yet considered the question. The question is one in which other countries are more closely concerned than this country, but the position is being watched by my department, and, if it appears desirable, steps will be taken to raise the question before the Opium Advisory Committee of the League.

Supervision of Mentally Defective Children.

Lieut.-Colonel FREMANTLE asked the President of the Board of Education what steps, if any, were being taken for the supervision of mentally deficient children eligible for admission to special schools for whom accommodation in such schools was not available.—Mr. C. TREVELYAN replied: The board have been in consultation for some months past on this subject with representative bodies and persons concerned with the welfare of mentally defective children. They hope to issue a circular on the subject at an early date.

The Standard of Overcrowding.

Mr. ERNEST SIMON asked the Minister of Health whether, seeing that the standard of overcrowding generally adopted by medical officers of health was two persons per room, and that it was possible, without exceeding this standard, to have serious overcrowding and such conditions that elementary decency was impossible, he would instruct medical officers of health to adopt a new standard more in accordance with present-day opinion.—Mr. WHEATLEY replied: I am advised that the census figures as to families living under conditions of more than two persons per room have never been regarded by medical officers of health as other than a rough index of the prevalence and distribution of overcrowding conditions, and that there is general agreement among health officers that other considerations must be taken into account. As at present advised I do not think that any specific instruction to medical officers on this point is necessary or would serve any useful purpose.

Examination of School-children.

Mr. WINDSOR asked the President of the Board of Education if, in view of complaints received, he would issue instructions to medical officers that when examining school-children such examination should be in private, and that information with reference to the child's health and general condition should be private and confidential to the parents or guardian.—Mr. CHARLES TREVELYAN replied: It has been the consistent policy of the Board to insist that the medical inspection of school-children shall be conducted in private with the utmost regard for the feelings of the children and their parents. Moreover, in 1908, shortly after the inception of the School Medical Service, the Board instructed local education authorities that all entries of the results of inspection in each individual case must be regarded as confidential, and this instruction has been in force ever since. I am not aware of any complaints in this connexion, but I shall be quite ready to inquire into any cases in which it is alleged that the practice advocated by the Board has not been followed.

Cost of Relief.

Mr. CECIL WILSON asked the Minister of Health whether he could state for the years 1913–14 and 1922–23 the average cost per head of children in children's homes and children boarded out; the average cost per head of indoor relief in the case of the aged, the sick, the able-bodied, and the insane; and the average cost per head in asylums.—Mr. WHEATLEY replied: The average weekly cost per head in 1922–23 of children in separate establishments for children in England and Wales in respect of in-maintenance—i.e., for food, clothing, and necessaries, but excluding the cost of officers' salaries and rations, buildings, and loan charges—was, in those institutions for which separate accounts were kept, 8*s.* 8¼*d.* The average weekly cost per head of children boarded out in the same year was 10*s.* 9*d.* I regret that similar figures are not available for the year 1913–14. The average cost per head of indoor relief in the case of the aged, the sick, the able-bodied, and the insane, cannot be given separately for either of the years in question, but the average weekly cost per head for all classes of persons receiving indoor relief was, in the year 1913–14, 13*s.* 2¾*d.*, and in the year 1921–22, 31*s.* 0¾*d.* The average weekly cost per head for maintenance of patients in county and county borough mental hospitals in England and Wales was for the year 1913–14, 10*s.* 9½*d.*, and for the year 1922–23, 23*s.* 9½*d.*

FRIDAY, FEB. 22ND.

Machine-skimmed Milk for Infants.

Commander BELLAIRS asked the Minister of Health, in view of the danger to infant welfare from the unfit food that was imported as machine-skimmed milk, whether he would consider proposals to prohibit the import by imposing a minimum fat standard.—Mr. WHEATLEY replied: Under the Public Health (Condensed Milk) Regulations, 1923, condensed machine-skimmed milk is required to be labelled as "unfit for babies." I see no reason for prohibiting its importation as I am advised that, though the removal of fat renders it unsuitable for feeding babies, it is not an unwholesome food and may properly be included in mixed dietaries.

MONDAY, FEB. 25TH.

Plight of the Hospitals.

Mr. MARCH asked the Minister of Health whether his attention had been called to the straitened circumstances of many hospitals; and whether he was prepared to introduce a comprehensive health system on a national basis, in order to cope with the demand for treatment and remove the need for charitable support.—Mr. A. GREENWOOD replied: The position of the voluntary hospitals, though it is still difficult, has greatly improved since the report of Lord Cave's Committee. The proposal contained in the second part of the question is one with which my right hon. friend has some sympathy, but it raises far-reaching issues, both medical and financial, and he is not at present prepared to give any undertaking as to it.

Industrial Diseases.

Mr. CLARKE asked the Minister of Health if, in view of the fact that spirochætosis ictero-hæmorrhagica had now been made a notifiable disease by regulation of the Board, he would consider the advisability of having it included under the industrial diseases clause of the Compensation Act.—Mr. RHYS DAVIES (Under-Secretary to the Home Office, who replied), said: I understand that this disease is not notifiable in England, but that as a result of a recent outbreak in East Lothian it has been made notifiable in Scotland by an Order of the Scottish Board of Health. Before the disease can be scheduled under the Workmen's Compensation Act it must be shown to be due to the nature of some employment, and to be so specific to that employment that its origin can be established in individual cases. On my present information the disease in question would not appear to come within this category, but I shall be prepared to consider the point further when I have obtained a fuller report.

TUESDAY, FEB. 26TH.

National Insurance.

Lord HENRY CAVENDISH-BENTINCK asked the Prime Minister whether he was prepared to extend the terms of reference of the promised Royal Commission on National Health Insurance to cover the whole field of a general social insurance, designed to provide security to the worker and his dependents in cases of industrial accidents, industrial diseases, non-industrial accidents, ill-health, maternity, unemployment, old age, blindness, burial, unprovided widowhood, and unprovided orphanhood.—Mr. CLYNES replied: I do not think it would be desirable to extend the terms of reference of the proposed Royal Commission in the manner suggested by the noble lord. There is ample material for investigation within the limits proposed. The better coördination of the various social services is a separate matter which is receiving consideration.

Poor-law Vaccination.

Mr. BROMFIELD asked the Minister of Health if he would state what was the cause of the increase in expenditure on vaccination by Poor-law authorities in England and Wales during the year 1920–21 as compared with the previous year, the respective figures being £174,927 and £124,018.—Mr. A. GREENWOOD replied: The increase in expenditure on vaccination by Poor-law authorities during the year 1920–21, as compared with the previous year, was mainly due to the increase in the number of births and the consequent increase in the number of children vaccinated by public vaccinators during 1920 as compared with 1919.

THE HOSPITAL SYSTEM OF DUBLIN.—The President of the Royal College of Surgeons in Ireland (Sir W. I. de C. Wheeler), in a speech at a public dinner last week, made some severe criticisms on the Dublin hospital system. It was probably, he said, the worst in the world. There were 12 or 14 small hospitals, many of them built 200 or 300 years ago, and used in the heart of the slums, in the worst possible situation as far as the sick were concerned. If he had had any influence with the contending parties a few years ago, he would have asked them to give time to remove the patients and then to blow up the hospitals. It would have been a real benefit to Ireland, and new buildings on the Edinburgh system, would have cost only about half a million. Our Dublin correspondent adds: Though most thoughtful people will agree that the needs of Dublin could be better served by one or two large hospitals than by 12 small ones, nevertheless the President's strictures appear somewhat severe. Of hospitals, as of forms of government, it is sometimes true that "whatever is best administered is best."

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—R. D. Jones, Edinburgh ; W. McLaren, Durham ; and H. J. Powell, St. Mary's Hosp.

Medicine.—J. B. Sweet, Glasgow.

Forensic Medicine.—R. Caplan, Glasgow ; L. K. Htoe, London ; E. G. R. Mac Mahon, St. Thomas's Hosp. ; M. S. Mahmud, St. Mary's Hosp. ; W. McLaren, Durham ; I. Morgan, St. Mary's Hosp. ; and A. M. Shawket, Liverpool.

Midwifery.—R. Hare, St. Mary's Hosp. ; F. James and R. Schofield, Guy's Hosp. ; and R. D. Marett Tims, Cambridge and St. Thomas's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery : R. Caplan, M. S. Mahmud, W. McLaren, H. J. Powell, and J. B. Sweet.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Council meeting held on Feb. 14th the diploma of Member was granted to the following candidates who have passed the requisite examinations and have complied with the by-laws :—

R. D. Alexander, Cambridge and St. Thomas's ; C. F. Ashby, St. Bart.'s ; J. Atkin, Guy's ; N. F. Azer, Cairo and Charing Cross ; R. C. Baxter, Charing Cross ; H. P. Baylis, Guy's ; J. Bee, London ; E. R. Bennion, Westminster ; Muriel E. Binns, Royal Free ; C. E. W. Bower, Manchester ; M. A. B. Brito-Mutunayagam, Ceylon and St. Thomas's ; W. Brockbank, Cambridge and Manchester ; R. W. Brookfield, Liverpool ; W. G. S. Brown, Cambridge and St. Bart.'s ; R. E. D. Cargill, Oxford and St. Bart.'s ; H. D. Chalke and J. H. H. Chataway, St. Bart.'s ; Nora Cheney, King's Coll. ; R. Chester, Leeds ; W. Clark, Charing Cross ; G. D. Clarke, London ; R. G. Cochrane and T. S. Cochrane, St. Bart.'s ; P. S. Connan, King's Coll. ; A. M. Cooke, Oxford and St. Thomas's ; Rosemary Cooke, Cambridge and Charing Cross ; S. S. Cruden, St. Bart.'s ; D. E. Cuffey, Cambridge and King's Coll. ; E. R. Cullinan, St. Bart.'s ; Vera Cullwick, Birmingham ; C. H. C. Dalton, Cambridge and St. Bart.'s ; A. F. D. Darlington, Cambridge and St. Thomas's ; A. B. Davies, Guy's ; J. H. T. Davies and P. O. Davies, Cambridge and St. Bart.'s ; T. Davies, St. Bart.'s ; Dorothy L. C. Day, London ; A. M. Deane, St. Thomas's ; J. S. Dees, Middlesex ; A. De Souza, Cambridge and Middlesex ; G. P. Driver, St. Bart.'s ; W. H. Dunn, St. Thomas's ; Winifred P. Edmunds, King's Coll. ; Barbara J. Edwards, Birmingham ; J. Elgood and G. Elliot, St. Bart.'s ; V. H. Ellis, London ; A. C. M. Elman, Univ. Coll. ; T. J. Evans, Middlesex ; E. K. A. Firth, St. Thomas's ; T. F. Fox, Cambridge and London ; E. S. Frischmann, Manchester ; M. W. M. Gadrat, Paris ; P. Garson, St. Bart.'s ; W. H. George, London ; H. M. Golding, Bristol ; H. P. Goldsmith, Univ. Coll. ; W. Gough and F. E. Gould, Birmingham ; A. W. Grace, Univ. Coll. ; H. Graf, Liverpool ; F. H. K. Green, St. Bart.'s ; C. W. Greenway, Guy's ; R. J. Gregory, St. George's ; W. E. Grice, Middlesex ; A. B. Griffiths, Liverpool ; G. J. Griffiths, Middlesex ; R. D. Gross, Guy's ; S. A. Gunter, St. Bart.'s ; J. A. E. M. Hadley and L. W. Hale, Univ. Coll. ; C. S. Hallpike, Guy's ; J. G. Hamilton, London ; I. E. Harries, Guy's ; K. E. Harris, Cambridge and Univ. Coll. ; A. W. Hart Perry, St. Bart.'s ; R. C. Hatcher, Bristol ; Leila M. Hawksley, Royal Free ; L. I. Henzell, Univ. Coll. ; J. C. W. Hewetson, Guy's ; Gabrielle M. Highfield-Jones, Charing Cross ; E. W. Hicks, St. Thomas's ; H. A. Hirst, London ; J. A. Hislop, Durham ; S. A. Holford, Middlesex ; J. Holmes, Cambridge and St. Bart.'s ; A. Hooper, Leeds ; Gwynedd Hugh-Jones and Kathleen M. Hyslop, Royal Free ; Ethel J. Isaacs, Westminster ; S. P. Jacobson, Guy's ; H. Jaffe, Manchester ; T. G. I. James, Cardiff ; J. W. W. Jepps, Cambridge and St. George's ; A. T. Jones and W. Jones, Univ. Coll. ; P. C. Worseldine, Guy's.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful :—

FINAL EXAMINATION FOR DEGREES OF M.B., CH.B.

Part I. (including Forensic Medicine and Toxicology).—Arthur F. Alford, Kenneth F. Alford, David H. Beatson, Elizabeth E. Benson, Harry W. Brassington, Dorothy E. Crellin, Sidney J. H. Griffiths, Constance I. Ham, Frederick H. Hollingshead, John A. Hooker, Charles T. Hyatt, Arthur H. Lowther, Rosalie E. Lucas, Cecil P. Porter, David C. Prowse, Lennox G. Robertson, Herbert Rogers John F. Southward, Gertrude M. Terrell, Maria M. Tewater, Thomas W. Ware, and Kathleen M. Willmore.

Part I. only.—Gilbert M. Minifie.

Part II. (completing Examination.)—John A. James (first-class honours), Arthur P. Bodman and Herbert Taylor (second-class honours), Naomi J. Bown, Gilbert B. Bush, William L. Cossham, Frank R. Edbrooke, Norman J. England, Herbert M. Golding, Rowland C. Hatcher, Alexander G. Heron, Frederick G. Jenkins, Muriel V. Joscelyne, Patrick C. Joscelyne, Eric C. K. Kenderdine, Edgar F. King, Carrie H. Osmond, and Robert A. Sammons.

SECOND PROFESSIONAL EXAMINATION FOR DIPLOMA IN DENTAL SURGERY.

Sydney Phillips.

In Dental Mechanics and Dental Metallurgy only.—Christopher S. Cossham.

EXAMINATION FOR DIPLOMA IN PUBLIC HEALTH.

In Part I. only.—Eric G. Don.

FINAL EXAMINATION FOR DEGREE OF B.D.S.

Edgar K. Tratman.

FINAL PROFESSIONAL EXAMINATION FOR DIPLOMA IN DENTAL SURGERY.

Reginald G. Downes, George J. Kelly, and Brenda F. Taylor.

The degree of M.D. has been conferred on Mr. Macdonald Critchley for a dissertation on the Parathyroids and Calcium Metabolism.

HUNTERIAN SOCIETY.—The Hunterian oration on the Changing Standpoints in Cardiac Medicine will be delivered by Sir Sydney Russell-Wells on March 3rd at 9 P.M. at the Mansion House. A discussion will follow, to be opened by Dr. J. Strickland Goodall and Dr. B. H. Parsons-Smith.

RONTGEN SOCIETY.—A general meeting will be held on March 4th at 8.15 P.M. in the Institution of Electrical Engineers, Savoy-place, Victoria Embankment, London, W.C., when a paper on Hard and Soft Tubes in the Technique of Radiography, with a practical demonstration, will be read by Mr. N. E. Luboshez. The seventh Silvanus Thompson Memorial Lecture will be delivered by Prof. C. G. Barkla, F.R.S., at a general meeting of the society to be held at the Institution of Electrical Engineers on April 1st.

LONDON SCHOOL OF TROPICAL MEDICINE.—The Langley prize of about £30 will be awarded this year. This prize is open to competition among officers of the West African Medical Staff, whether on the active or retired list. The award will be made in respect of the best paper written on one of the following subjects : (*a*) Tropical Medicine or Surgery. (*b*) Tropical Hygiene and Sanitation. (*c*) Tropical Entomology and Parasitology. Papers should be delivered to the Secretary, Seamen's Hospital Society, Greenwich, London, S.E., on or before Oct. 1st, 1924.

RIVERS MEMORIAL FUND.—Friends and admirers of the late W. H. R. Rivers who have not yet subscribed, or by inadvertence have not been invited to subscribe, to this fund are asked to communicate with the treasurer, Dr. L. E. Shore, St. John's College, Cambridge. Subscribers are invited to attend a meeting which will be held at the rooms of the Royal Society, Burlington House, at 4 P.M. on March 25th, in order to decide on the form which the memorial should take.

Dr. Hugh Thursfield has succeeded Sir Dyce Duckworth as hon. consulting physician to the St. John's Foundation School, Leatherhead, for Sons of Poor Clergy.

THE Wellcome Museum of Tropical Medicine and Hygiene at 25-27, Endsleigh-gardens, London, N.W. 1, will be closed from March 1st until further notice, as it is proposed considerably to enlarge the museum.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The Charter Day dinner will be held in the College Hall, St. Stephen's Green, West Dublin, on Saturday, March 1st, at 7.30 P.M., when the principal guest will be H.E. the Governor-General.

THE LATE DR. E. J. DICKINSON.—Elmer John Dickinson, who died at Pietermaritzburg, Natal, on Feb. 4th, aged 37, was born in Canada, graduating M.D. at Winnipeg University in 1916. During the war he served with distinction as a captain in the Canadian Royal Army Medical Corps, gaining the Military Cross and the Croix de Guerre with palms. Although he had been but three years in Natal, his ability and genial personality had enabled him to build up a large practice in Pietermaritzburg.

OXFORD UNIVERSITY PRESS.—To celebrate its moving from Amen Corner into Warwick-square, the Oxford University Press is holding a luncheon on Tuesday, March 4th, at the new building. The Marquess Curzon, Chancellor of Oxford University, will preside, and the Archbishop of Canterbury and Mr. Asquith will propose the toast of the University. In his reply, Lord Curzon will propose the toast of the University of Cambridge, whose Chancellor, Lord Balfour, will reply.

METRIC SYSTEM IN U.S.A.—It is reported that a Metric Standards Bill, providing for gradual adoption in the United States of the metric units of weights and measures in commerce, has been brought before the House of Representatives and the Senate. According to the provisions of the Bill, the buying and selling of goods, wares, and merchandise will be in terms of the metric units after a period of ten years.

BRITISH SCIENCE GUILD.—A science news service has been inaugurated by the Guild with the object of providing in the lay press a weekly signed article dealing with some subject of special interest and a weekly column of science notes. It will also furnish reports of scientific progress. Scientific workers prepared to act as correspondents for the laboratories in which they are working are requested to communicate with Mr. Gordon D. Knox, 2, Guilford-street, London, W.C. 1.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The Royal Northern Hospital has arranged, in conjunction with the Central London Ophthalmic Hospital, the North-Eastern Fever Hospital, and the Royal Chest Hospital, to give a two weeks' intensive course, including all the general and special departments of medicine and surgery, from March 3rd to March 15th. Two afternoon sessions will be at the Central London Ophthalmic Hospital, one at the Royal Chest Hospital, and one morning session at the North-Eastern Fever Hospital. Apart from these demonstrations at other hospitals all the work will be undertaken by the members of the staff at the Royal Northern Hospital, and will include demonstrations of clinical methods and cases, lecture-demonstrations, and work in the wards and out-patient department from 10.30 to 5.30 each day. A special course in gynæcology will take place at the Chelsea Hospital for Women from March 3rd to March 28th. Clinical demonstrations and lectures will be given in the wards and out-patient department to be followed by lectures or operations in the theatre. Dr. Porter Phillips and Dr. Thomas Beaton will give a series of lecture-demonstrations in psychological medicine at Bethlem Royal Hospital from March 8th to April 5th. The demonstrations will be given on Thursdays and Saturdays at 11 A.M., and will deal with diagnosis and symptomatology of mental diseases, the psycho-neuroses, and the medico-legal aspects of insanity. Also a series of six lecture-demonstrations dealing with recent advances in medical electrical treatment will be given by Dr. C. B. Heald at the Royal Free Hospital on Wednesdays at 5.30 P.M. from March 5th to April 9th. A course on diseases of children has been arranged by the Royal Waterloo Hospital for Children and Women from March 17th to April 5th. The course will include lecture-demonstrations, ward work, out-patient cliniques each day from 2 o'clock onwards. Copies of the syllabus, with full particulars of the above courses and the fees payable for each course can be obtained on application to the secretary to the Fellowship of Medicine, at 1, Wimpole-street, London, W.

EDINBURGH: ROYAL MEDICAL SOCIETY.—The annual dinner of this Society was held on Feb. 21st in the Hall of the Royal College of Surgeons, Edinburgh. About 130 members were present and the guests included Prof. Gulland, Prof. Harold Stiles, Sir Robert Philip, Mr. J. Condie Sandeman, K.C. (Dean of the Faculty of Advocates), Sir Leslie Mackenzie, Prof. W. P. Patterson, D.D., Sir Byron Bramwell, and Sir J. Balfour Paul. Sir George Newman, as the guest of the evening, spoke of the future of medicine and its ever-extending rôle in the development of civilisation. He paid a generous tribute to the notable part played by the medical schools of Edinburgh, forming a great and imperial university, in furthering the art and science of medicine. Sir Harold Stiles, in replying to the toast of the Edinburgh Medical School, expressed the hope that more money would be available for preventive work along which lines the future of medicine must lie.

THE LATE DR. J. W. MULLEN.—The death of John William Mullen, L.R.C.S. & P. Irel., took place on Feb. 17th, at Ladywell Sanatorium, Pendleton, in his sixty-seventh year. A native of Dublin, Dr. Mullen was educated at Bective College, after obtaining his medical qualifications at the Royal Colleges of Surgeons and Physicians of Ireland. He went to Manchester, and at the age of 24 was appointed to the Wilton Fever Hospital, Salford, which was then of small dimensions. There he remained until the erection about 20 years ago of the Ladywell Sanatorium, an institution to which he devoted all his energies. Dr. Mullen held the position of medical superintendent of the Salford Corporation Hospitals for 43 years, and under his guidance and unselfish devotion to the Ladywell Sanatorium it became a model of its kind. Dr. Mullen is survived by a widow and daughter.

SUSSEX MATERNITY AND WOMEN'S HOSPITAL.—In future the Brighton and Hove Hospital for Women will be known by this name. The change of title was unanimously agreed upon at the annual meeting of the governors on Feb. 13th, when it was explained that the alteration was desirable owing to the confusion existing between the hospital and the institution in the town known as the New Women's Hospital. Owing to recent legislation the hospital had had to take in a large number of cases for the local authorities of a class which they did not previously deal with, and this had been one of the factors which had actuated the governors to take larger premises last year. The scheme for fitting up vacant rooms as wards for private patients paying full fees had been proceeded with, and the accommodation in this respect was nine beds, a private labour ward, a bathroom, and an office. Practitioners sending patients into these wards may attend them there should they so desire. Dr. R. D. Smedley, medical officer of health for West Sussex, in a short address on maternity work, warmly acknowledged the coöperation and the facilities for treatment granted by the hospital so readily eight years ago to the West Sussex County Council upon the inauguration of its maternity and child welfare work. With the increased accommodation the in-patients during 1923 numbered 614, as compared with 387 in 1922. Of these 234 were midwifery cases undertaken for the local authorities. The work on the district had been less by some 200 cases, which the governors attributed to the fall in the birth-rate. Out-patients increased from 648 to 676. Lady Burrell was elected President in succession to Lady Leconfield.

Appointments.

HUNT, E. R., M.D., B.C. Cantab., M.R.C.P. Lond., has been appointed Honorary Consulting Physician to the Haywards Heath Hospital.

JENNINGS, H. C., M.B., B.S., D.P.H., Temporary Medical Officer of Health to the Holland County Council.

Certifying Surgeons under the Factory and Workshop Acts: BUCHANAN, R. F. C. H., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg. (Coniston); LINDSAY, A., M.B., Ch.B. Glasg. (Nantgaredig); HENDERSON, J. M., M.B., Ch.B. Edin. (Greenlaw).

Vacancies.

For further information refer to the advertisement columns.

Bath Ear, Nose and Throat Hospital, Marlborough Buildings.—Hon. Pathologist.

Birmingham, Highbury, Uffculme and Sorrento Hospitals.—Med. Supt. £800.

Bradford Children's Hospital.—H.S. £125.

rdiff, King Edward VII Welsh National.—Asst. R.M.O.'s. £375 and £250 respectively.
ntral London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.
aring Cross Hospital, W.C.—Asst. Obstet. P.
ncaster Royal Infirmary.—Sen. H.S. £200.
eter, Royal Devon and Exeter Hospital.—H.P. £150.
derated Malay States, Central Mental Hospital.—Asst. Med. Supt. £616.

est London Hospital, Hammersmith-road, W.—One H.P. and Two H.S.'s. Each £100.

Births, Marriages, and Deaths.

BIRTHS.

IGGER.—On Feb. 24th, at Brackenhurst, Walton-on-Thames, the wife of W. G. Bigger, M.B., B.Ch., of a son.
RAIMBRIDGE.—On Feb. 10th, at Wigmore-street, W., the wife of Dr. C. V. Braimbridge, Kenya Medical Service, of a son.
ARLISLE.—On Feb. 17th, at "Ardlair," Heswall, Cheshire, the wife of H. G. Carlisle, M.D., of a daughter.
RAMER.—On Feb. 14th, at The Pryors, Hampstead, the wife of Dr. William Cramer, of a son.
OWLER.—On Feb. 22nd, at Pinewood, Wokingham, Berks, the wife of William C. Fowler, M.D., B.S. Lond., of a son.
REENWOOD.—On Feb. 23rd, 1924, at 55, Crouch Hall-road, Crouch End, N. 8, the wife of A. Atkins Greenwood, M.B., B.S., M.R.C.S., L.R.C.P., of a daughter.
EBERT.—On Feb. 24th, at Wigmore-street, the wife of G. T. Hebert, M.D., of a daughter.

MARRIAGES.

OBB—WALLACE.—On Feb. 21st, in London, Captain Campbell Robb, R.A.M.C. (retired), to Marjorie Macneil Wallace, elder daughter of the late Alexander Scott, M.D., of Glasgow.

DEATHS.

STIN.—On Feb. 19th, at Gwylfa, Maerdy, Corwen, suddenly, Wilson Astin, M.B., C.M., aged 60 years.
ATE.—On Feb. 20th, of pneumonia, at Millbank Hospital, Colonel A. L. F. Bate, C.M.G., A.M.S.
OND.—On Feb. 20th, at Torquay, of pneumonia, William Arthur Bond, M.D., F.R.C.P. (late M.O.H., Holborn), aged 67 years.
ANSDOWN.—On Feb. 17th, at Oakfield-road, Clifton, Bristol, Robert Guthrie Poole Lansdown, M.D., B.S., M.R.C.S., L.R.C.P., aged 60 years.
ACNAIR.—On Feb. 16th, in a nursing home, London, Alfred Duncan Macnair, M.D. Glasg., The Grange Drive, Winchmore Hill, N.
OSS.—On Feb. 19th, at Porchester-road, Bournemouth, Daniel McClure Ross, M.D., F.R.C.S., in his 75th year.
PURGIN.—On Feb. 15th, at Dallington, Northampton, Herbert Branwhite Spurgin, M.R.C.S. Eng., L.S.A. Lond., aged 81 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

SOCIETIES.

THE ROYAL SOCIETY.

THURSDAY, March 6th, at 4.30 P.M.—*Papers to be read:* E. D. Adrian, F.R.S. and Sybil Cooper: The Electric Response in Reflex Contractions of Spinal and Decerebrate Preparations. A. Fleming: A Comparison of the Activities of Antiseptics on Bacteria and on Leucocytes. (Communicated by Sir Almroth Wright, F.R.S.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, March 3rd.

TROPICAL DISEASES AND PARASITOLOGY: at 8.30 P.M.
Paper:
Lieut.-Colonel R. McCarrison, I.M.S. (Pasteur Institute of Southern India): Rice in Relation to Beri-beri in India.
N.B.—Members of the Sections of Medicine, Pathology, and Therapeutics and Pharmacology are specially invited to attend this meeting.

Tuesday, March 4th.

ORTHOPÆDICS: at 5.30 P.M. (Cases at 5 P.M.)
Cases:
Mr. Laming Evans: Cases of Congenital Hemiplegia in Similar Twins.
Mr. Bernard Roth: (1) Bony Ankylosis of Elbow, (2) Fractured Clavicle treated by Sayre's Method with Resulting Paresis.
Mr. S. L. Higgs: Specimen of Congenital Absence of Sacrum.
Cases will also be shown by Mr. McCrae Aitken, Mr. R. C. Elmslie, and Mr. Gordon Pugh.

PATHOLOGY: at 8.30 P.M. At the Lister Institute, Chelsea-gardens, S.W.
Communications:
Dr. S. P. Bedson and Dr. M. E. Johnston: Further Observations on the Genesis of Platelets.
Mr. H. Schütze: Results of treating Tuberculous Guinea-pigs with Diaplyte Vaccine.
Dr. J. A. Arkwright and Mr. A. N. Goyle: The Relation of "Rough" and "Smooth" Variants to the "O" and "H" Forms of Weil and Felix.
Mr. M. L. Cowan: Experimental Production of Immunity to Streptococci in Rabbits.
Dr. E. E. Atkin: A Comparison of Meningococcal and Gonococcal Colonies on a Special Medium.

Wednesday, March 5th.

MEDICINE, SURGERY, THERAPEUTICS AND PHARMACOLOGY: at 5.30 P.M. (to be adjourned to 8.30 P.M. if necessary).
Joint Discussion on
The Treatment of Severe Gastric and Duodenal Hæmorrhage, Mr. Cyril A. R. Nitch (President of the Section of Surgery) in the chair.
Speakers:
Surgical: Mr. H. J. Paterson (opener), Mr. A. H. Burgess, Mr. R. P. Rowlands, Mr. G. Gordon-Taylor.
Medical: Sir William Willcox, Dr. A. Hurst, Dr. Izod Bennett.
Therapeutical: Dr. P. Hamill.

Thursday, March 6th.

BALNEOLOGY AND CLIMATOLOGY: at 5.30 P.M.
Paper:
Dr. J. Burt: On the Causes of Brachialgia.

STUDY OF DISEASE IN CHILDREN, NEUROLOGY, OBSTETRICS AND GYNÆCOLOGY, ORTHOPÆDICS: at 8 P.M.
Joint Discussion on
Birth Injuries, with Special Reference to Intracranial Injuries with Hæmorrhage, and to Nerve Injuries.
Opener: Mr. Eardley Holland (Obstetrics and Gynæcology).
Other Speakers: Dr. Collier (Neurology), Mr. Fairbank (Orthopædics), Dr. Cameron (Study of Disease in Children).

Friday, March 7th.

LARYNGOLOGY: at 5 P.M. (Cases at 4 P.M.)
Discussion on
Suppurative Diseases of the Frontal, Ethmoidal, and Sphenoidal Sinuses.
Illustrative cases will be shown.
The following have promised to take part in the Discussion: Mr. Herbert Tilley, Sir StClair Thomson, Sir William Milligan, Mr. E. Watson-Williams, Mr. Logan Turner, Dr. P. Watson-Williams, Dr. W. T. Gardiner.

ANÆSTHETICS: at 8.30 P.M.
Paper:
Prof. Storm van Leeuwen (Professor of Pharmacology, University of Leyden): The Anæsthetic Properties of the Purest Ether: Ether of Crystallisation.
N.B.—Members of the Section of Therapeutics and Pharmacology are specially invited to attend this Meeting.

Saturday, March 8th.

OTOLOGY: at 10 A.M. (Cases at 9.15 A.M.)
Cases and Specimens:
Mr. Richard Lake: (1) Case of Vertigo, probably Central in Origin; (2) (with Dr. E. A. Peters) a Thick Flap for the Partial Lining and Diminution of Too Large

Mastoid Cavities; (3) Forceps for Use in Tonsillar Dissection.
Dr. Collier (introduced by Mr. Richard Lake): (1) Abscess of Lateral Sinus; (2) Cerebral Abscess.
Cases will also be shown by Sir James Dundas-Grant, Dr. Dan McKenzie, Mr. T. B. Jobson, and others.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
WEDNESDAY, March 5th.—9 P.M., Dr. R. A. Young: The Treatment of Pulmonary Tuberculosis. (Second Lettsomian Lecture.)

HUNTERIAN SOCIETY.
MONDAY, March 3rd.—9 P.M. (at The London Mansion House). Sir Sydney Russell-Wells: Changing Standpoints in Cardiac Medicine. (Hunterian Oration.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, March 3rd, to Saturday, March 8th.—BETHLEM ROYAL HOSPITAL. Course in Psychological Medicine: Sat., 11 A.M., Dr. Porter Phillips: Diagnosis and Symptomatology of Mental Diseases.—CHELSEA HOSPITAL FOR WOMEN. Daily: Operations, &c. Mon., 2 P.M., Mr. Giles: Tues., 5 P.M., Mr. Bonney: Mechanism of Genital Displacement; Wed., 2 P.M., Mr. Galletly: Case-taking. Demonstration in Wards: 4 P.M., Mr. Ellison: Pelvic Pain; Thurs., 2 P.M., Mr. Giles: Obstetrics and Gynæcology in Relation to the State; Fri., 2 P.M., Mr. Banister: Disorders of Micturition.—ROYAL FREE HOSPITAL. Wed., 5.30 P.M., Dr. Heald: The Diathermy Current—Its Uses and Applications.—ROYAL NORTHERN HOSPITAL, in conjunction with the CENTRAL LONDON OPHTHALMIC HOSPITAL, NORTH-EASTERN FEVER HOSPITAL, and ROYAL CHEST HOSPITAL. Special Intensive Course (first week), as per Syllabus.
Further particulars can be obtained from the office at 1, Wimpole-street, W. 1.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, March 3rd.—10 A.M., Surgical Registrar: Surgical Pathology. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Simson: Diseases of Women.
TUESDAY.—12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards. 2.30 P.M., Dr. Pritchard: Medical Wards.
WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
FRIDAY.—10.30 A.M., Dr. Pritchard: Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Banks-Davis: Diseases of Throat, Nose and Ear.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital).
(At 4.30 P.M.)
(Open to Members of the College only.)
MONDAY, March 3rd.—Mr. Aubrey Goodwin: Retroversion.
TUESDAY.—Mr. C. H. Hayton: Septic Sinus Thrombosis of Otitic Origin.
THURSDAY.—Mr. J. Bright Banister: Prolapse.
FRIDAY.—Dr. L. R. Yealland: Clinical Demonstration of Cases.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
TUESDAY, March 4th.—5 P.M., Dr. Whitfield: Lichen Planus.
THURSDAY.—5 P.M., Dr Fox (Chesterfield Lecture): Cutaneous Syphilis.

ST. THOMAS'S HOSPITAL, Albert Embankment, S.W.
(In the Governors' Hall.)
THURSDAY, March 6th.—5 P.M., Dr. J. A. Murray: Cancer. (Third Lecture.)

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.
THURSDAY, March 6th.—4 P.M., Dr. A. M. H. Gray: Ringworm.

CANCER HOSPITAL, Kensington, S.W.
WEDNESDAY, March 5th.—4.30 P.M., Dr. Stanley Wyard: Cancer of the Stomach.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
THURSDAY, March 6th.—5 P.M., Mr. W. Gilliatt: Eclampsia and its Treatment.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, W.
TUESDAY, March 4th.—5.15 P.M., Mr. Joseph Barcroft, F.R.S.: The Respiratory Pigments in Animal Life and Their Significance. (Lecture IV.)
FRIDAY.—9 P.M., Dr. Walter Rosenhain, F.R.S.: The Inner Structure of Alloys.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, March 5th.—4 P.M., Dr. B. T. J. Glover: Difficulties in the Campaign against Tuberculosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.
POST-GRADUATE COURSE: FEBRUARY–MARCH, 1924.
CLINICAL LECTURES AND DEMONSTRATIONS.
MONDAY, March 3rd.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Clinical Types of Paraplegia: Dr. Aldren Turner.
TUESDAY, March 4th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Subacute Combined Degeneration: Dr. Adie.
THURSDAY, March 6th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Electrical Reaction of Muscles: Dr. Bailey.
FRIDAY, March 7th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Neurosyphilis: Dr. James Collier.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.
MONDAY, March 3rd.—12 noon, Subacute Combined Degeneration and Other Forms of Combined Sclerosis: Dr. J. G. Greenfield.
The fee for the Course, including Pathology, is £5 5s. For those who hold Perpetual Tickets the fee is £3 3s.

COURSE OF LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.
WEDNESDAY, March 5th.—12 noon, Afferent Systems to Thalamus and Cortex.
THURSDAY, March 6th.—12 noon, Cerebral Cortex: Function; Projection Systems: Dr. Kinnier Wilson.
The fee for this Course will be £2 2s.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE NEUROLOGY OF THE EYES.
WEDNESDAY, March 5th.—3.30 P.M., Ocular Palsies and Disturbances of Ocular Movement: Mr. Leslie Paton.
The fee for this Course alone is £5 5s. If taken in conjunction with the general Post-Graduate Course the fee is £3 3s. All applications should be sent to the Secretary, Medical School.
Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.
Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.
J. G. GREENFIELD, Dean of Medical School.

VICTORIA UNIVERSITY OF MANCHESTER MEDICAL SCHOOL.
THURSDAY, March 6th.—5.30 P.M., Prof. Fawcett: The Development, Normal and Abnormal, of the Bones around the Mouth.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
TUESDAY, March 4th.—4.15 P.M., Dr. W. E. Fothergill: Puerperal Pelvic Infection.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE (at Whitworth-street West Branch).
FRIDAY, March 7th.—4.30 P.M., Dr. J. W. Bride: Hæmorrhage in Association with Pregnancy, Labour, and the Puerperium.

ANCOATS HOSPITAL LECTURES.
THURSDAY, March 6th.—4.30 P.M., Dr. Norman Kletz: Rheumatoid Arthritis and Allied Conditions.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)
MONDAY, March 3rd.—(At the Children's Hospital.) Mr. McMurray: Congenital Deformities.
TUESDAY.—(At the Southern Hospital.) Dr. J. H. Mather: X Rays in the Diagnosis of Phthisis.
WEDNESDAY.—(At the Northern Hospital) Dr. Cunningham: Acidosis.
THURSDAY.—(At the Stanley Hospital.) Mr. F. Strong-Heaney: Infections of the Bladder and Kidneys.
FRIDAY.—(At the Royal Infirmary.) Dr. Wallace Jones: Some Points in the Prognosis and Treatment of Kidney Disease.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES. (At 3.30 P.M.)
TUESDAY, March 4th.—(At the Royal Infirmary.) Mr. Finch: Diagnosis and Treatment of Injury to the Semilunar Cartilages.
FRIDAY.—(At the Royal Hospital.) Prof. Hall: The Clinical Significance of Headache.

DECREASE OF DRUNKENNESS IN RUGBY.—At the annual licensing sessions held recently in Rugby Dr. Clement Dukes, the chairman, commented on the encouraging decrease in arrests for drunkenness in the town for the past decade. The improvement had been steady and remarkable; in 1911, the figures showed a rate of 37 per 10,000 of the population, while in 1921 the proportion had sunk to 4·60 per 10,000. Viewing these facts in their widest interpretation, Dr. Dukes said it was evident that we, as a nation, are sobering ourselves, and have learnt the sensible course of taking a glass too little instead of a glass too much. Prohibition, he continued, was no remedy for drunkenness, State control might, as he had shown, do a great deal, but the highest and best remedy was self-control.

Notes, Comments, and Abstracts.

THE ADMINISTRATION OF BENEFITS UNDER THE NATIONAL HEALTH INSURANCE SYSTEM OF ENGLAND.[1]

BY H. S. BEADLES, M.R.C.S. ENG.,
CHAIRMAN OF THE WEST HAM INSURANCE COMMITTEE; SECRETARY OF THE WEST HAM LOCAL MEDICAL AND PANEL COMMITTEES.

THE primary and most excellent postulate of the National Insurance Act of 1911—the enjoyment of nine pennyworth of benefits for the contribution of 4*d.* per week—has not been realised. Indeed, such realisation was doomed at the birth of the scheme through the dissection of the limbs from the trunk by the instrument creating it. The scheme purports to be national; but there are few, if any, approved societies which represent all classes and types of the insured community. The authors of the Act of 1911, in choosing the friendly and industrial societies as the media for carrying out the administration of cash benefits, ignored the diversity of causes from which the existence of such societies had sprung. Those existing in 1911 owed their origin to a variety of motives. Some were the result of the unity of persons of particular schools of thought, particular trades or callings, of peculiar health standards, and otherwise. Even members of those which purport to embrace individuals irrespective of class or creed must, in their societies' development, become reduced to a common level of health standard differing from that of other societies. Yet all societies are credited with income upon the assumption of a general national average risk, notwithstanding that a preponderance of healthy lives has become grouped together in some societies while a preponderance of unhealthy lives exists in others.

Different Benefits in Different Societies.

Differentiation in the benefits accruing to the insured persons thus becomes inevitable. The member of one society finds himself entitled to extra sick pay, extra disablement benefit, higher maternity benefit, dental treatment, and what not. His brother, having joined a society of less healthy people, finds himself entitled to the minimum benefits under the original Act, to maintain which he is called upon to pay higher contributions under a penalty for non-compliance, of having the required amount deducted a number of times over from any of the said minimum cash benefits to which he may, at some future date, become a claimant.

Examine the provisions for the extra benefits and the penalties for deficiencies to which reference is made, and see how these things have actually worked out on first valuation. Section 37 of the National Insurance Act of 1911 confers powers upon societies showing surpluses on valuation to submit for the approval of the Minister of Health schemes for the distribution of such surpluses by way of conferring upon their members any one or more of the additional benefits set out in Part III. of the Fourth Schedule to the Act. These are: Medical treatment of dependents, dental treatment, increased sick pay or disablement pay, or the payment of such benefits in certain contingencies, increased maternity benefit, convalescent homes, pensions and superannuation allowances, payments to persons in want or distress, &c. It will be seen that these benefits might well be classified as either "benefits in cash" or "benefits in kind." With regard to the deficiencies provisions, Section 38 of the National Insurance Act, 1911, requires societies with expenditures in excess of incomes disclosed by valuation to submit schemes to the Minister of Health for making good the losses, either by compulsory levy or increase of the weekly rate of contribution, by reduction of sick pay, for either the whole, or part, of any period during which such benefit is payable, by otherwise altering the conditions attaching to the payment of cash benefits, or by any other method approved by the Minister.

Valuation Results.

In the Ministry of Health's 1919–20 annual report on national health insurance, particulars are given of the issue to approved societies in England of their valuation reports, and of the initial work in connexion with the adoption of schemes of additional benefits. It appears that the schemes of additional benefits adopted in England do not cover about 1,000,000 insured persons of England. Moreover, the Minister of Health points out in his report that with lapse in membership, and the influx of new members, there is a constant tendency to reduction in the number of members who are entitled to additional benefits during the currency of a scheme.

The degree of confusion into which the so-called national health insurance has sunk will be readily appreciated upon realisation of the extraordinary number of departures from the original benefits offered by the Act of 1911, and the consequent variations in the types of benefits enjoyed by one insured person, compared with another, as disclosed by the official statements of additional benefits. This is the result of the first valuation. If the system is allowed to continue, subsequent valuations can only result in intensification of the confusion.

Can one conceive a more illogical and pernicious system than this? One million persons have been compelled to join groups of their fellows in order to endeavour to insure themselves against contingencies. Having done so, they find themselves made parties to the gamble—"premiums based upon general average risks of the insured community; opposed to contingencies only covered to the limited extent allowed by the average health experiences within the confines of the societies in which they find themselves."

It means, in effect, that if they are members of societies having unhealthy membership, some of their fourpences per week are providing ninepences and more for the members of the societies having healthy membership. In addition, they may be called upon to contribute some additional pennies or so per week in order to become entitled to even the minimum benefits contemplated by the Act.

The extraordinary thing about the situation of these unfortunate victims of the system is that, should they desire and take steps to put themselves on a par with their more fortunate brothers by transferring their membership of society, they find themselves "up against" most formidable forces of obstruction; and even should they by chance overcome these, they only enter new societies upon the condition that they do not participate in any extra benefits that may be enjoyed by the members of longer standing.

Administration of Additional Benefits Unsatisfactory.

The administration of extra benefits, more particularly of those in kind, such as dental and the so-called optical treatment, and nursing benefit, is unsatisfactory. Notwithstanding the provisions of Section 14 (1) of the original Act that additional benefits in the nature of medical benefits should be administered territorially, the approved societies, with utter disregard to the convenience and best interests of their members, laid claim to, and secured, the right to manage dental, optical, and nursing schemes. A completely new business organisation was set up under some such title as "Beneficent Society" purporting to conduct negotiations on terms with representative organisations of opticians and dentists, and otherwise to act on behalf of societies including these services in their schemes. Scales of charges have been prepared and issued to all the societies interested throughout the country. So far as my district is concerned, there appears to have been little, if any, effort made to acquaint the insured persons generally of their rights in relation to either dental or optical treatment or nursing. In cases where the insured person has, by rumour or hearsay, become aware of the means whereby he can obtain these benefits, and has applied for one or other of them with some means of success, his hopes have subsequently been shattered by the unwillingness of his society to pay the whole cost of his requirements as estimated by the dentist or optician, as the case may be. The optical treatment previously mentioned has proved in actual practice to have resolved itself into the supply of glasses by opticians and not to treatment by ophthalmic surgeons. The dangers of this practice cannot be exaggerated, and it is certainly not giving to insured persons treatment equivalent to that available to the ordinary uninsured individual.

There are signs that advantage is being taken of the opportunities afforded by this system of administration to create incentives whereby business is caused to flow to certain establishments to the exclusion of others.

I do not here propose to go very deeply into the subject of deposit contributors. Suffice it to say that the disabilities suffered by the members of a weak society are intensified in the case of these contributors, and under no stretch of imagination can it be said that the contributions extracted from them represent insurance premiums. The better definition might well be the compulsory temporary segregation of wages and trade funds for no good purpose, and without interest-earning power. Yet this class is bound to exist under the approved society system of administration. If a deposit contributor suffers from an unhealthy record, approved societies do not want him, and will not have him. If he enjoys a healthy record, he probably remains a deposit contributor because he wants nothing to do with approved societies.

Section 63.

No Act of Parliament of modern times has conferred a greater power of improving the health conditions of the community at large than that given to approved societies under Section 63 of the National Health Insurance Act, 1911.

[1] An abstract of papers which appeared in the National Insurance Gazette of Dec. 15th and 22nd, 1923.

relating to excessive sickness caused by inadequate public health precautions, insufficient or insanitary housing, &c. Yet in actual practice the approved societies, through the very nature of their constitution and wide membership, are rendered incapable of performing the necessary inquiries, and undertaking successfully the required steps to secure observance of the Public Health or Housing of the Working Classes Laws. Much less can a society consisting of members employed in abnormally unhealthy trades address itself to the problem.

The distribution of cash benefits should be closely linked with the task of restoring the sick to good health, the provision of preventive treatment, and the maintenance of the good health of the community. Every certificate issued by the insurance practitioner represents a cheque drawn upon the insurance bank and the public purse. Approved societies are certainly not the instruments through which such link can be satisfactorily established and maintained.

THE QUEEN'S DOLL'S HOUSE.

To the Editor of THE LANCET.

SIR,—One always hesitates to criticise a chef-d'œuvre, but a work which aims at being an exposition of the perfect house of to-day should be, like Cæsar's wife, above suspicion. The penalty of being an expert is to have to find fault where one would wish to concur, and in regard to one aspect of the domestic hygiene of the Queen's Doll's House the sanitary expert finds himself in this dilemma.

No plan of the Doll's House has been published, but from the illustrations of the actual rooms it can be perceived that the relation of certain apartments could not but seriously qualify the sanitary certificate of an independent professional adviser. That the arrangement in question is expressly against the by-laws has, of course, no force in this instance of a royal palace, and for the expert the question is governed solely by the laws of sanitary science. In modern house-planning de luxe, especially in continental practice, it is becoming very common to discount some of the fundamental principles of sound sanitation, but the fact remains that what may be immediate advantages are only secured at the risk of ultimate danger to health.

It will be seen that the criticism of this letter is actually directed against a modern tendency to relax the vigilance inspired by the work of sanitary pioneers. But the great historical significance of the wonderful achievement of the Queen's Doll's House is, I trust, sufficient justification for my calling in question this one intimate detail of it.

I am, Sir, yours faithfully,

London, Feb. 23rd, 1924. SANITARY EXPERT.

COMPARATIVE MORTALITY IN THE METROPOLITAN BOROUGHS.

IN reply to a question addressed to him in the House of Commons a few days ago the Minister of Health gave comparative figures of mortality in the several Metropolitan boroughs as shown below:—

"ACOUSTIQUE" ELECTRICAL AIDS FOR THE DEAF.

THE Acoustique Company, of 95, Wigmore-street, London, W., have submitted to us a selection from their newest styles of apparatus. They state that they have introduced a new type of transmitter which is now to be employed in all their instruments; it is very light and flat, so that a single transmitter can be worn quite conveniently under the lapel of the coat. The more powerful instruments have three or four transmitters and, in some models, these can be placed in a box for use as a table-instrument or taken out and worn on the person. In one ingenious model the microphones are accessible, so that a broken carbon can be removed and replaced; this should be a great convenience to those living in distant countries, and one may hope that this improvement will eventually be possible on all the apparatus. The table instruments are particularly small, light and powerful, and are fitted with a resistance to moderate the strength of current. In all the tone is round and pleasing, and there is a remarkable absence of "buzz" or extraneous sound; this can be still further eliminated by the use of the "non-head attachment," which consists of an indiarubber tube to be screwed into the receiver and attached to a nipple to fit into the meatus, and which has now been improved by the addition of a hook-shaped metal tube to fit comfortably over the pinna. The prices range from 3½ to 25 guineas.

BLOOD-SUPPLY OF THE BRAIN IN THE OX.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to an article by Dr. Leonard Hill in your issue of Dec. 22nd, 1923, on the Humanity of Methods of Slaughter. I quite agree with the conclusions to which he comes and the suitability of the method of slaughter which he supports, but I disagree with one of his statements of fact. In the section referring to throat-cutting he states that it must be borne in mind that the vertebral arteries do not also supply the brain of cattle, but end in the muscles of the head. This is not so. The vertebral arteries certainly supply the brain of the ox. I have recently dissected these arteries and find that the description and figure in Sisson's "Anatomy of the Domestic Animals" are correct. This book states that a continuation of the vertebral artery passes forwards to the floor of the cranium and concurs with the condyloid and branches of the internal maxillary artery in the formation of a large rete mirabile. The latter takes the place of the internal carotids. It is thus clear that the arteries under discussion carry blood to the brain in the ox as in the horse. But I should expect that the cutting of the two common carotids would bring about such an immediate fall of blood pressure in the common brachio-cephalic trunk that the amount of blood passing to the brain by the vertebrals would be negligible. This is proved by the manometer experiment upon the calf. I am, Sir, yours faithfully,

BERNARD GORTON.

Royal Veterinary College, Camden Town,

An Address
ON
DISEASE OF THE STOMACH AND ITS SURGICAL TREATMENT.

Delivered at the Surgical Section of the Royal Academy of Medicine in Ireland, on Feb. 29th, 1924,

BY JAMES SHERREN, C.B.E., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL, ETC.

I HAVE purposely left the title of my address vague, s I wish to touch upon several topics and draw ttention to unsolved points in connexion with disease f the stomach.

The surgery of chronic ulcer of the stomach—I nclude in this term what is embryologically stomach, he duodenum to the entrance of the common bile-uct—is in a transitional state, and we have to resort ill to operative measures, which are either mutilating, hysiologically unsound, or both. It must remain n this condition until we have obtained exact know-dge of the cause of the disease; we can then treat ie patient before these procedures become necessary. Ve must, I think, look on it somewhat as a reproach, iat lesions, which should be capable of curative eatment by simple means, are allowed to progress ntil direct interference with the stomach is required restore the patient to health. I do not consider ie results of the operations we are carrying out nsatisfactory; far from it, they are excellent, in me cases little short of miraculous. In chronic lcer, they far exceed those obtained by any form of iedical treatment, whether looked upon from the oint of view of cure or of the risk attaching thereto.

PREVENTABLE ABDOMINAL EMERGENCIES.

As long ago as 1911,[1] in a paper dealing with the revention of abdominal emergencies, I expressed the pinion that perforation of a gastric or duodenal ulcer curs in patients in whom, "in the majority of cases, mptoms have existed for weeks, months, or years, hich should have led to the recognition of organic sease and surgical treatment before urgency arose." went on as follows: "It has fallen to my lot several mes to operate on cases of duodenal and gastric ulcer hich had perforated while they were having ambu-tory medical treatment for dyspepsia variously amed." My experience since has abundantly con-med this; and further, I have had to operate on veral patients whose chronic ulcers had perforated, caused hæmorrhage while they were undergoing a urse of medical treatment in bed.

The preventable nature of many of these emer-ncies is corroborated by the London Hospital gures. Thus, among 218 cases of perforated iodenal ulcer treated at the London Hospital, in x only was there no previous history of indigestion. milar figures were obtained in 248 cases of perforated stric ulcer. In hæmorrhage due to a chronic ulcer e same applies. As the majority of these patients d had more than one course of medical treatment, veral had been having intermittent treatment for years and one for 32, we are perfectly justified in nsidering them as failures of that treatment, and, surgery was unable to be employed successfully in ese emergencies, the mortality is medical rather an surgical. This is a view I have frequently pressed, and is one which has also been ably put rward by Sir Berkeley Moynihan,[2] and recently has oked medical criticism; it is undoubtedly correct at the mortality of the medical treatment of chronic cers is vastly greater than the surgical.

DEFINITION AND STATISTICS OF CURE.

I work in the belief that surgery provides in the ajority of cases a cure, and I am now using this term the sense in which it is understood by the laity—that is, a permanent abolition of symptoms. Those of us who have been operating upon large numbers of patients with these diseases have traced their after-history from year to year, and are able to speak authoritatively in the matter. In my Hunterian lecture[3] in 1920, I gave my reasons for considering those patients as cured who had gone two years without any symptoms whatever. I wish to emphasise this. None of those who came within that category and were then quite well have had further trouble. Three men, however, among those "not well" developed secondary ulcer, one a true jejunal, and two gastro-jejunal ulcers due to unabsorbable sutures, one after a chronic gastric, and one after a chronic duodenal ulcer. Patients who go for two years without symptoms never develop them later. I have found that in the rare cases of severe symptoms, six, eight, or more years after operation, the first two years were never uneventful.

I want briefly to supplement the records in that lecture, thus bringing the results up to date (to Jan. 1, 1924). In what follows I am using the term chronic ulcer to mean an ulcer that can be seen, felt, and demonstrated to others, or, as Moynihan has put it, "a visible and palpable lesion." To that date I had treated by operation 768 cases of chronic duodenal ulcer, with 15 deaths, including those operated on for hæmorrhage, 78 in number, among whom there were six deaths. I have been able to trace 500 who were operated on before January, 1922; 463 are, and have remained perfectly well. In this series, of 152 additional cases, two developed secondary ulcers, one described in that lecture and one I shall mention later. The cases of chronic gastric ulcer, operated upon to Jan. 1st, 1924, number 600 with 28 deaths. These figures include all treated except for acute perforation. I have similarly traced 403 cases, operated on before January, 1922; 311 were and had remained perfectly well; among the additional cases, one developed an anastomotic ulcer and was operated on by another surgeon, and eleven had minor complaints, but they were small. I should like to confirm what I have previously stated with regard to partial gastrectomy.[4] Its results are remarkable. I have been carrying it out regularly for certain cases of chronic gastric ulcer, and enlarging its indications for over eleven years. I have never known secondary ulceration to follow, and its after-history seems to be singularly uneventful.

Among 903 cases of chronic gastric and duodenal ulcer traced for over two years, 774 have remained absolutely well, 29 have developed secondary ulceration. In three of these the second operation was not done by myself. The letters from patients are overwhelming in their gratitude; I will quote one case as an example. In November, 1913, I operated upon a woman of 30, with a 14 years' history of attacks of epigastric pain with occasional vomiting, and one severe bout of hæmatemesis. I found an hour-glass stomach due to recurrent ulceration on the lesser curvature, with much scarring, and did a posterior gastro-jejunostomy to its cardiac side, at the same time removing her appendix. Her husband wrote on Jan. 25th, 1924, saying "whereas before the operation food of any kind resulted in absolute torture for her, she is now able to enjoy good meals and not fear after-effects." It has been my experience that, as with this patient, the remote results continue as satisfactory as the immediate.

PATHOLOGICAL PROOF OF HEALING.

But we have not only the clinical proof, the cure as understood by the laity, we have the pathological, the healing of the ulcer being demonstrated at post-mortem, long periods after the operation, or at second operations undertaken for other conditions. I have always maintained that chronic ulcers of the duodenum, unless adherent to and eroding the pancreas, heal as the result of gastro-jejunostomy, as do free ulcers on the lesser curvature of the stomach when the

[1] Clinical Journal, Sept. 6th, 1911.

[3] THE LANCET, 1920, i., 691.
[4] Hunterian Lecture, loc. cit.

anastomosis is done to their cardiac side. I have had the opportunity of examining, up to 12 years after operation, 31 cases of chronic duodenal ulcer, and 25 of chronic gastric. The ulcer had healed in all. I have never seen an ulcer unhealed at a remote period subsequent to gastro-jejunostomy, if that procedure was indicated and was carried out on correct lines.

CAUSES OF OCCASIONAL FAILURE TO CURE.

In spite of this, however, we very occasionally fail to "cure" the patient. The failures may be mechanical or ulcerative, both now exceedingly rare. The mechanical, revealing itself by bilious vomiting, is associated with imperfect technique, and failures from this cause become fewer and fewer with experience, but perhaps may be unavoidable on occasions for anatomical reasons, if gastro-jejunostomy is performed. I refer particularly to patients with a short or fat transverse meso-colon, or an ulcer high on the lesser curvature or posterior surface. These cases exercise one's ingenuity, and in them I endeavour to avoid gastro-jejunostomy.

Until we are accurately acquainted with the cause of gastric and duodenal ulcer, secondary ulceration will occasionally occur, although our treatment has brought about the healing of the original lesion. It seems to me hopeful that a further study of the conditions under which secondary ulcer arises may throw light on the ætiology of the primary one. I am firmly convinced that infection is the cause of gastric and duodenal ulcers. The infection may reach the stomach by the blood-stream from the mouth or abdomen or, in the latter case, the lymphatics, as suggested by Braithwaite,[5] in his work on the lymphatic flow from the ileocæcal angle. The association of acute ulcers of the stomach with abdominal infections, particularly from the appendix, is well known and demonstrated post mortem.

ACUTE ULCERS OF THE STOMACH.

Acute ulcers of the stomach are much more common than it is now fashionable to think. I believe the older physicians were right in considering the pain, vomiting, and hæmatemesis of young women due to acute gastric ulceration. These symptoms are not, of course, confined to any age or sex, but are typically met with in women between 20 and 30.

It is true that these ulcers are small, but what is the limit of the size of an ulcer? We should look on these lesions as definitely ulcers, but we must not let this conception of the condition make us advise gastric operations for their cure; we should treat their cause. We know that they usually heal readily and often relapse. They cannot be seen on external examination of the stomach, often not when the mucous membrane is directly inspected during life, and after death may only be discovered with the greatest difficulty, but in all cases of hæmatemesis in patients with this type of symptoms that have died after operation, I have been able to find acute ulcers. During the early years of gastric surgery it was customary to operate immediately on cases of profuse hæmatemesis; it is from experience gained during this period that I make the statement.

I have operated on 63 patients for hæmatemesis of this nature, not due to chronic gastric or duodenal ulcer and presumably due to acute ulceration. Three of the early cases died; in all the stomach itself had been explored at the operation and nothing found, and in all acute ulcers were demonstrated post mortem. These cases in their previous history resembled those who recovered, in whom I was unable to demonstrate an acute ulcer.

Unfortunately, diagnosis is only made possible by hæmorrhage, or very rarely by perforation, so that only in these cases is treatment at present possible. It should be on surgical lines—rest to the diseased part and removal of infection. This would, I am sure, save many from the development of chronic ulcer and the later onset of carcinoma. That acute ulcer is often followed by the chronic variety and the latter by carcinoma is undoubted. The larger my experience of gastric surgery, the more strongly do I hold the view that carcinoma is a frequent complication of chronic ulcer, which should be ever present in our mind when advising and undertaking treatment. Hardly a week passes in which I do not operate on some patient, with a history extending over many years so definite that gastric ulcer could be diagnosed—only to find carcinoma too late for removal. While revising this address I have explored a man with a history of attacks of pain after food extending over many years and diagnosed ten years previously as ulcer, who for the past nine months had had no remission, it proved to be advanced carcinoma; the day previous to this a patient who is the most recent illustration of the connexion, acute ulcer, chronic ulcer, carcinoma.

A woman of 59 came under my care with the following history: At the age of 35 she had an acute painless hæmatemesis of a severe nature. She then had occasional attacks of "indigestion" to which she paid little attention until four years previously, when she began to get definite attacks of pain after food lasting two to three weeks, with intervals of three or four months of perfect health. For three months before I saw her she had had pain every day with occasional vomiting. At operation, on Feb. 12th, I found inoperable carcinoma of the body of the stomach.

The cases of presumably acute ulcers with hæmatemesis should be given morphia and as much water by the mouth as the patient wishes. Such treatment as an ice-bag to the epigastrium, withholding of all fluid by the mouth, is illogical. Patients suffering from the results of hæmorrhage should be kept warm; ice applied to the epigastrium would have the opposite effect, and although it might constrict the superficial vessels it certainly would not have this effect on those of the stomach, rather the reverse. Sucking ice is similarly unwise. There is no reason whatever to withhold water, it can do no harm. Operation should *never* be carried out in these acute cases with hæmatemesis. The acute ulcer cannot be dealt with directly; gastro-jejunostomy cannot check the bleeding and adds enormously to the mortality, which is low. When the bleeding has ceased, every effort must be made to arrive at a diagnosis of the cause; splenic conditions, carcinoma of the stomach, cirrhosis of liver being borne in mind, as they may each cause hæmorrhage without any prodromal symptoms. If acute ulcer is the diagnosis, careful search should be made for septic foci, in the mouth, naso-pharynx, ears, and such dealt with. If no external exciting cause is discovered, the question of abdominal exploration should be considered, and I am of the opinion it is the safest procedure. In any case, if relapse occurs it should not be delayed longer than to give the patient time to recover sufficiently from the effect of the bleeding. Dealing with infection in the abdomen may prevent the formation of other acute ulcers and their development into a chronic condition. I am firmly convinced that this treatment prevents the occurrence of further acute ulcers.

Among these 63 cases explored are 29 in which definite disease of the appendix was present, in 27 no further hæmorrhage took place. In two it recurred within a year, and it is a striking fact that in both these patients the disease in the appendix was only discovered on microscopic examination, to the naked eye it was normal. All these were over three years ago, 13 of them over five. The following is a recent and most striking instance in a boy of 12 who was not restored to health without surgical intervention.

He was admitted to the wards of the medical unit, under the care of the director, Dr. Charles Miller, in January, 1921. He had had a profuse hæmatemesis, with a relapse in three days and a further hæmorrhage the day after his admission. He remained in hospital for three months and then went to a convalescent home for five weeks. He was readmitted in September after a further hæmatemesis, which recurred after he had been in hospital four days. There was no evidence of any external infection; at no time had he had pain or indigestion. As his condition remained unsatisfactory and he was not recovering, I was asked to see him, and on

[5] Brit. Jour. Surg., July, 1923, p. 7.

an. 10th, 1922, I operated; the stomach and duodenum, ver and spleen, were normal. The gall-bladder appeared ormal. I explored it internally, took a specimen of bile. nd removed the appendix, which was thickened and ontained fluid. Films of this showed pus and many acteria. Cultures from gall-bladder were sterile. He is ow in perfect health and started work last August.

The infection may be in the gall-bladder and reated equally successfully. I have previously published [6] examples of acute ulcer, with hæmorrhage and erforation, associated with infection of the gall-ladder, the patients being free from gastric symptoms ow eight and 12 years ago. Previously to January, 922, I had removed the gall-bladder in 11 patients ith hæmatemesis. Since that date I have operated n four and in all cultures of the bile grew colon acilli. In none has there been any recurrence of astric symptoms.

In a large number of cases of chronic gastric ulcer n women we find a definite history of attacks of ainless hæmatemesis and of vague discomfort after od, caused, I believe, by the acute ulcer before the nset of the typical chronic ulcer symptoms. I am f the opinion that treating the acute ulceration when e can diagnose it, in the way I have suggested, will revent the development of chronic ulcer. Not only re the cases I have quoted clinical evidence of my elief, but I have been able to keep some patients nder special observation. I am surgeon to the ursing staff and am thus fortunate, in that I am able o follow up the cases. I have operated upon three urses who had had attacks of hæmatemesis such as attribute to acute ulceration. As there was no xternal cause of infection I explored and removed the ppendix, which was the only obviously diseased rgan. All three have remained well and at work or eight, nine, and ten years. We are not, however, lways successful; we may fail to discover the cause, r be too late in its removal, so that the ulcer may ecur or become chronic. The cause of chronicity we now, from Bolton's experimental work, to be excess f acid and delay in emptying the stomach. Clinical onfirmation of this is obtained from the healing of ronic ulcers after gastro-jejunostomy, when acidity lowered and gastric stasis abolished.

RECURRENT ACUTE ULCER.

There is a variety of ulcer little recognised, met with ost often in women, particularly those with gastric tosis, and frequently associated with repeated ttacks of hæmatemesis; it is the recurrent or relaps-ng acute ulcer, with definite healing taking place etween the attacks. The scarring which results ay produce an hour-glass stomach and in about per cent. of the cases at the time of operation for is condition the ulcer has healed. If not producing eformity the scars are easily overlooked and only evealed on careful search and are usually found close the lesser curvature on the posterior surface of the omach. Unless producing deformity, treatment ould be directed towards other abdominal organs, otably the appendix and gall-bladder, to deal with e causative infection. These ulcers relapse, even hen soundly healed. The following is a good xample: In November, 1913, I operated upon a oman, aged 30, who gave a 14 years' history of eriods of pain after food, with three attacks of ematemesis. I found an hour-glass stomach with a rait which would only admit my index finger. xploration of the stomach revealed no recent ulcera-on, there was much visceroptosis, and I decided would be worth while doing a gastro-gastrostomy; vo and a half years later I had to do a partial strectomy on account of recurrence of symptoms. he specimen showed the anastomosis perfect, with ecent acute ulceration in a scarred area on the posterior rface of the stomach. This patient has remained rfectly well.

What is the relationship that exists between the cute ulcer, the relapsing, and the solitary chronic round ulcer, the last variety so much more common in men, the well-known penetrating type which when situated on the posterior surface of the stomach involves the pancreas? These latter ulcers rarely cause an hour-glass stomach; when one is found in association it is usually due to the scar tissue formed by the healing of relapsing ulcers. I believe that the difference is to be found in the much greater acidity of the gastric contents in men than in women. In women the lower gastric acidity allows healing of the ulcer, the contraction of the scar tissue so produced accounts for the hour-glass stomach. This will explain why this relapsing type is so much more common in women and why hour-glass stomach is so rarely met with in men. I believe that in the true chronic ulcer healing does not take place between the attacks. As evidence of this we have acute perforation, by no means uncommon, or hæmorrhage, when the patient is apparently well. Spread in this variety results in perforation into the free peritoneal cavity, or erosion of the pancreas or liver and occasional hæmorrhage. It is this ulcer which is the precursor of malignant disease. The scars that are frequently found in the post-mortem room are not the scars of this type which destroy all the coats, but those of relapsing or acute ulcers.

I am convinced that they all own one cause and that it is possible, as I mentioned before, to arrest the disease before it reaches a chronic stage when nothing but a direct operation on the stomach is of avail. The following case seems to me to illustrate the development of a chronic ulcer from an acute. I believe that if abdominal exploration had been carried out earlier, as in the case I have quoted, it would have been possible to have prevented this.

In December, 1923, I operated on a girl of 24 with the following history: At the age of 17 she was treated in hospital for an attack of painless hæmatemesis. She had a further attack in 1920 when she was again treated in hospital. In November, 1922, she was once more admitted as she had begun to experience pain after food; her test-meal was then normal. After medical treatment she remained well for a year when she again had symptoms and was again an in-patient. On this occasion her test-meal was free HCl 0·26, total acidity 78, a very marked increase. After admission she had a copious hæmorrhage, vomiting blood on five occasions. At operation I found a chronic ulcer on the anterior surface of the first part of the duodenum which I destroyed by cautery and performed a posterior gastro-jejunostomy. I then looked for evidence of infection; the gall-bladder appeared normal on external and internal examination, but the appendix was fibrotic in its terminal half and the pathological report was chronic appendicitis. She left hospital for convalescent home 14 days later with a test-meal finding of free HCl 0·0 and total acidity 23.

This case seems to illustrate the transformation of an acute into a chronic ulcer with rise in gastric acidity, in spite of medical treatment under the best possible conditions.

It has fallen to my lot on several occasions to have to explore on the diagnosis of ulcer and find none, only to have to re-operate a few years later and discover a large ulcer. The following is an example:—

In October, 1915, I saw a woman of 31 with a history of attacks of pain of three to four weeks' duration with free intervals of about a month, which had extended over three years. Test-meal normal, free HCl 0·09, total acidity 49; barium meal negative. I explored and found a suspicious scarred area on the lesser curvature, but no definite evidence of ulceration. I therefore opened the stomach widely on its anterior surface and searched with a head light and speculum. I could discover no ulcer. I removed her appendix which was bound down at its base and contained a soft concretion; my note says, "but was otherwise normal." Microscopical report—"slight submucous fibrosis and muscular hypertrophy of tip of appendix." She remained well for a year, and her symptoms recurred and for the eight months before she again came to see me she had had pain and vomiting. Her test-meal showed increase (free HCl 0·12, total acidity 60) and the barium meal a penetrating ulcer. Two years after the first operation I did a partial gastrectomy for an ulcer on the lesser curvature and posterior surface which was eroding the pancreas posteriorly for an area of 1 by ¾ inch. On examining the part removed I found a linear scar where I had opened the stomach, far removed from the ulcer. She has remained quite well.

[6] Lectures on Stomach and Duodenum, 1921, p. 12.

This case is an example showing that the relapsing type of ulcer may become the chronic.

I have also had to operate on several patients who had been explored by others for hæmatemesis and after a lapse of years found a definite chronic gastric ulcer. Similarly, I know of two patients of my own whom I explored for ulcer on account of hæmorrhage and in whom, similarly, a chronic ulcer was found by other surgeons.

HOUR-GLASS STOMACH.

To pass now to a further consideration of a subject I have already mentioned, hour-glass stomach. It is astonishing that carcinoma so rarely supervenes on this condition. Thus, among 119 cases of hour-glass stomach operated upon up to Jan. 1st, 1924, there were only four cases of carcinoma, all women. In three of these the history pointed to it having followed on chronic ulcer. One case is unique in my experience; there were two chronic ulcers, one on the lesser curvature about an inch from the pylorus producing a large pyloric pouch and obviously malignant, and one high up on the lesser curvature with a small cardiac pouch. I successfully carried out partial gastrectomy. The report on the specimen by Dr. H. M. Turnbull showed that carcinomatous change had started in a simple ulcer and that the other ulcer was wholly innocent. In none of the 83 cases in which partial gastrectomy was carried out for hour-glass stomach due to what was diagnosed as simple ulcer was carcinoma discovered on microscopical examination. The great rarity of hour-glass stomach in men is striking. I have already mentioned what I considered the explanation of the frequency of this condition in women. Among the 114 cases of hour-glass stomach due to ulcer, only 12 were men, a very marked difference to the usual incidence. Thus, of 600 cases of chronic gastric ulcer operated on to Jan. 1st, 1924, 372 were men.

There is another point in connexion with hour-glass stomach in women: chronic duodenal ulceration is not infrequently found associated with it. The combination of the two is relatively no more often met with in women than in men, when looked at from the gastric ulcer standpoint; thus in 55 of my gastric ulcer cases duodenal ulceration was also present—30 men and 25 women. But we must remember that chronic duodenal ulcer itself is infinitely more common in men; thus of the 768 cases of chronic duodenal ulcer, 130 only were women, and it is striking that in the 25 of these in which gastric ulcer was present, an hour-glass stomach had been produced. In none among the 30 men was this complication found. I am under the impression that, as with acute appendicitis, ulcer is becoming a more common disease in women. Thus, in my first 100 cases operated on for chronic duodenal ulcer there were 16 women, in my last there were 27. A similar change is noted in chronic gastric ulcer. In my first 100 cases, 67 were men, in my last 100 only 59. It is difficult not to associate this with a similar striking change in the sex incidence in acute appendicitis. Thus, in the year 1922, 625 cases of acute appendicitis were operated on at the London Hospital, 278 were females (44·5 per cent.). In 1907, 311 cases were operated on; 109 (35 per cent.) only were female. I have taken only the acute cases, as in these there can be no dispute as to the diagnosis. Rendle Short,[7] in his paper on the causation of appendicitis, has also noted this. He wrote: "There used to be a marked disparity between the sexes, males being more liable. Many early figures gave the proportion as 3 males to 1 female. Of late years the difference has been less marked. In 1918, 1298 males died of the disease in England and Wales, and 1118 females."

It is not, I think, generally recognised that gastric and duodenal ulcer is often familial, and, although it is not using the term strictly correctly, hereditary. I have no doubt upon the subject, but Bolton[8] says there is no satisfactory evidence, although he quotes Dreschfeld[9] on the subject, who regarded the evidence as conclusive. I have many times operated on individuals of the same family, on several occasions after fatal disaster had happened to another member, from perforation, and have more often obtained a definite history of operations for the same condition in others. I think it unlikely that it has to do with the stomach itself, as in one member of the family the ulcer may be gastric, in another duodenal. I think the reason must be sought in the exciting cause. I have recognised for many years that disease of the appendix tends to run in families, father or mother, and then the children. I have operated on parents and children for acute appendicitis, not in an epidemic form but with the lapse of years. I have always looked upon this as being the result of some inherited anatomical peculiarity of the appendix tending to inefficient drainage, hence increasing the liability to infection. There can be now, at any rate among surgeons, no hesitation in accepting infection from the appendix as a cause of gastric and duodenal ulceration, and it appears to me that we have here the probable cause of the prevalence of ulcers in members of the same family. I have recently had a son sent to me, to be operated on for chronic ulcer at the age of 24, by his mother, upon whom I carried out partial gastrectomy for carcinoma 13 years previously, after she had had symptoms pointing to chronic gastric ulcer for 27 years, and many cases in which parents I had successfully operated on sent their children to undergo the same treatment. I have also had several cases in brothers and sisters; one that created a deep impression on me was an instance in which I did a partial gastrectomy for hour-glass stomach in one sister, the other was brought to me and at operation I found carcinoma had developed. The elder sister I operated upon in November, 1919. She was 38 years of age and gave a 21 years' history of attacks of pain after food. I found an hour-glass stomach due to an ulcer on the lesser curvature, extending to the posterior surface and eroding the pancreas, with much scarring on the anterior surface, with a large pyloric pouch from stenosis caused by a chronic duodenal ulcer. I did a partial gastrectomy and she has been in perfect health since. She sent her sister to me last March. She was 31 years of age with a ten years' history of attacks of pain after food which for the previous six months had continued without remission. I found inoperable carcinoma of the stomach. It is interesting to compare the two end-results and to speculate on the reason for their difference: the gastric ulcer in the one case leading to an hour-glass stomach, in the other carcinoma. Were we able to solve this problem we should be very near victory over malignant disease.

SECONDARY ULCERATION.

Unfortunately, we have sometimes the opportunity of tracing the development of a chronic ulcer in the secondary lesion that may arise after gastro-jejunostomy. We know that at the time the anastomosis is made there is no ulceration in the jejunum. We also know from the classical animal experiments of Bolton that in order to produce gastric ulceration there must be damage to the mucous membrane and a certain degree of free acid in the gastric contents, and that the healing of these may be delayed and the lesion become chronic in the presence of an excess of free HCl. The damage to the mucous membrane of the jejunum may be brought about by infection that we failed to treat at the original operation. Another form of damage is the use of unabsorbable suture and bruising by clamps. But I do not believe that any of these, except the use of unabsorbable sutures, is sufficient in itself. If the operation permanently abolishes free HCl in the gastric juice, chronic ulceration does not occur. I drew attention to this in my Hunterian[10] lecture and, for reasons there given,

[7] Brit. Jour. of Surg., October, 1920, p. 174.
[8] Ulcer of Stomach, p. 15.
[9] Allbutt: 1910, vol. iii., p. 449.
[10] THE LANCET, 1920, i., 691.

onsider it an important cause. I think there is no oubt that a large opening removed from the pylorus roduces the greatest lowering of gastric acidity, and nterference with the pylorus by exclusion, or the resence of adhesions, is an important factor in eeping up the post-operative acidity. I am a whole-earted believer in the "physiological," or, as I prefer o call it, the chemical action of gastro-jejunostomy, s opposed to the purely mechanical. In a discussion t the Harveian Society,[11] I pointed out that if the ost-operative test-meal showed little or no reduction f acidity, although the stomach may be emptying apidly through the new opening, the patient may have urther digestive trouble. It is a subject at which I m still working but I can give a few results. First, will relate a case.

In March, 1920, I operated on a male patient aged 52. found a large ulcer of the first part of the duodenum with perforation at its centre closed by the gall-bladder which as definitely thickened. I separated these adhesions and losed the perforation. His condition would not allow any rther treatment. His pre-operative test-meal was free ICl 0·18, total acidity 75, his post-operative, free HCl 0·17, nd total acidity 63. At the present time, in a case of this ature, I should as soon as possible deal with the affected all-bladder and remove the appendix. He remained well for wo months only and then began to get the pain typical of jejunal ulcer; to the left of the umbilicus late after food, aking at 2 or 3 A.M., and relieved by food. I had him under bservation in September of the same year when his test-eal was free HCl 0·19, total acidity 79, and the barium eal report suggested ulcer at the stoma. I kept him in ed on alkalies, atropine, and diet, and at the end of three eeks he considered himself quite well and there was a slight owering of gastric acidity. Three months later the same ymptoms recurred and his test-meal was free HCl 0·18, otal acidity 70. I therefore re-operated on June 21st, 1921. found the duodenal ulcer healed and a chronic ulcer on the nterior surface of the jejunum. I did a partial gastrectomy; e had an uninterrupted recovery and his test-meal three eeks later showed free HCl 0 and total acidity 10. In his particular case the pylorus was interfered with in suturing he perforation and there was a definite focus of infection.

That increased gastric acidity is a most important actor in the development of secondary ulcers is ertain. I will briefly give you the reasons for coming o this conclusion. In the first place there is the great arity, as I have previously pointed out, of jejunal or astro-jejunal ulcer in women; it has only arisen in hree of my cases, in two it was directly due to a silk uture, in the third catgut only had been used, and the econd operation was carried out by another surgeon. ts very great rarity after operations for gastric ulcer n both sexes is also well known; I have only seen ne true jejunal ulcer. It occurred in 1911 in a male atient, aged 29, whose gastric acidity was higher fter operation than before, free HCl 0·11, total cidity 52, to free HCl 0·16 and total acidity 64. The peration had been difficult. I excised a chronic ulcer rom the centre of the lesser curvature and then did gastro-jejunostomy, and I noted that I was not atisfied with the size of the new opening. The ylorus was not excluded nor the appendix removed. hree months after the original operation I excised jejunal ulcer and removed his appendix, but his cidity remained high, free HCl 0·13 and total acidity 0, and I heard in 1920 that he had had a recurrence. he rarity of any variety of secondary lesion after peration for chronic gastric ulcer is, I think, explained y the lower acidity met with in this condition and to he fact that the post-operative acidity is very markedly educed in a large percentage of cases. Thus, in 123 ost-operative test-meals, after simple gastro-ejunostomy for a chronic gastric ulcer, in 99 there vas an absence of free HCl and a low total acidity, n 15 it was much diminished, in eight reduced to ormal, in only one not reduced—the case I have uoted.

To turn now to chronic duodenal ulcer. To the end f the year 1922 I have notes of pre- and post-perative test-meals on 285 cases of chronic duodenal lcer; 37 of these showed little or no reduction in gastric acidity, and in all of these except 11 I had made a special note of some abnormality, the most common being adhesion to the gall-bladder or liver (17 cases), opening nearer pylorus than usual (3), smaller than usual (2), ante-colic operation (1), bruising around anastomosis (clamp) (3). Seventeen have had further symptoms—five jejunal ulcers. In 131 cases free HCl was absent and the total acidity low; not one of these has had any return of symptoms. There are 65 cases in which there was very great reduction, but not to the abolition of free HCl; these are all perfectly satisfactory. Fifty-two in which it was reduced to normal; while most of these remain quite well, symptoms were present in five but none developed a jejunal ulcer. We have here, I am sure, material bearing very directly indeed on the production of ulcers, and it shows beyond a doubt how bound up it is with the question of gastric acidity. That there is some specific cause acting in the formation of jejunal ulcers is obvious from the fact of their frequent recurrence if they are simply excised, just as we know the frequency with which a chronic gastric or duodenal ulcer, which has perforated, will give rise to further symptoms, sometimes even to a second perforation with fatal results, unless curative measures are adopted. To prevent the occurrence of secondary ulceration all infective foci should be dealt with, no unabsorbable material or jejunal clamp used, and a large anastomosis made removed from the pylorus—in this way I have been able to reduce the incidence of this complication to the very small figure of 2 in 276 consecutive cases of gastro-jejunostomy for chronic ulcer, operated on more than two years ago.

I have tried to emphasise the importance of recognising and thoroughly treating acute ulcers, so that the onset of the chronic type may be prevented, and to point out that although by surgery chronic gastric and duodenal ulcer can be treated with little risk and a high percentage of cure our aim should be to prevent their occurrence.

Lettsomian Lectures

ON THE

TREATMENT OF

PULMONARY TUBERCULOSIS.

Delivered before the Medical Society of London

BY R. A. YOUNG, C.B.E., M.D., B.Sc.,
F.R.C.P. LOND.,
PHYSICIAN TO THE MIDDLESEX AND BROMPTON HOSPITALS.

LECTURE II.

(*Delivered on March 5th.*)

DIFFICULTIES in diagnosis are not the only problems which confront us in the management of a case of pulmonary tuberculosis. To determine the value of any method of treatment is a matter of singular difficulty. This is intelligible when we consider the long course of many cases, showing periods of activity and relative quiescence. The tendency to spontaneous arrest also complicates the decision as to the efficacy of a given mode of treatment. Moreover, M. L. Renon writes of "a normal coefficient of improvement" for any remedy, due largely to the psychic effect upon the patient. A most striking illustration of this is afforded by the observation of Mathieu and Dobrovici in 1906. They prepared certain patients for what they described as a valuable new remedy for the disease, and after careful records and the usual preparation accorded to patients undergoing a new treatment on its trial they gave daily injections of 1 c.cm. of normal saline, to which they gave the high sounding name of "anti-phymose." The results were strikingly similar to those we are accustomed to see recorded in the earlier

days of any new treatment. There was a marked amelioration of symptoms, fever abated and even an actual gain of weight occurred. Even in animals it would seem that it is easy to assume too hastily that a treatment is beneficial. Dr. E. H. Kettle, in a recent paper,[1] has urged that the criteria of cure in experimental animals like the guinea-pig, require more rigid analysis than they sometimes receive.

In view of these significant observations, which should be known and recognised as widely as possible, it is important for us all to adopt a critical attitude of mind in regard to any treatment and to moderate our enthusiasm until it can be demonstrated that it gives results superior to the "normal coefficient of improvement." We must avoid the attitude of the old lady who said, "It must be good, my dear, the advertisements speak so well of it" and adopt the Hunterian maxim, "Prove all things, hold fast that which is good." Judged by this standard many forms of treatment which have had more than an ephemeral vogue should be discarded. At the same time it is wrong to adopt the attitude that every treatment, other than that of the therapeutic triad, air, food, and rest is useless. Bearing in mind these considerations we may now briefly consider various forms of treatment which have been recommended.

SPECIFIC FORMS OF TREATMENT.

(*a*) *Tuberculin.*

Probably no remedy in the whole realm of therapeutics has been so widely debated as this. Since its introduction by Koch in 1891, it has been the subject of waves of enthusiasm and of depreciation. It has probably suffered more from the intemperate zeal of some of its advocates than from the criticism of impartial workers. That it has failed to realise the hope that it would be a specific cure for the disease there can be few to deny. On the other hand, that it can be a useful agent in treatment is well established. It is significant that it is in the localised or surgical forms of tuberculosis that it seems to have given the best results, while in the pulmonary forms of the disease it has proved most disappointing. Numerous attempts to modify it have been made and the list of products derived from the bacillus and from its culture media, which have been employed, is a very long one. Without any attempt to be exhaustive I have obtained a list of over 80 of these products. It is worthy of notice that in the treatment of the surgical forms the varieties of tuberculin used are few and are chiefly the early products of Koch—namely, old tuberculin, T.R., and B.E.—either of human or bovine origin. In pulmonary cases it has been found that a high degree of tolerance to tuberculin may be induced by administration of this substance to patients without cure of the disease; indeed, this tolerance may coexist with progressive activity of the pulmonary lesions. The reasons for these discrepancies are still obscure, but it is tempting to try to explain them in terms of the views on the pathology of the disease to which I referred in my first lecture. The surgical form corresponds to the secondary stage, when the immunity responses may be incomplete and tuberculin may be helpful, whereas in the pulmonary forms, as shown by Sir Almroth Wright, the hæmobactericidal power may be high, but the local condition may be active, and it may be, as he suggests, that the more fruitful line of attack may prove to be by increasing leucocytic activities.

Practically all tuberculins fall into three groups: (1) The soluble products of the growth of the tubercle bacillus, in various media, the exotoxins, of which the type is Koch's original old tuberculin (T.); (2) the insoluble residues of the bacterial bodies after extraction, of which the type is T.R.; (3) mixtures of both of these, such as B.E. More recently Much and Deycke have fractioned the bacillus in different ways and obtained different substances, which are called partial antigens or partigens. In treatment either the bovine or human forms of tuberculin may be used, and some authorities start with bovine and go on afterwards to human. Friedmann prepared a vaccine from bacilli from the turtle, which has been tried extensively in Germany and America. There seems little doubt that it has no advantages over other forms; indeed, Fishberg classes its results as entirely analogous to those of antipnymose, and therefore simply due to the psychic effect of a special treatment.

Effects of Tuberculin.—Tuberculin when injected into a person who has never had tuberculosis or been exposed to infection is a non-toxic substance. When given to those who have been infected or are allergic a tuberculin reaction occurs. This consists of three distinct effects: (*a*) A *local* reaction at the site of inoculation, which varies from transient redness and swelling to extensive infiltration of the subcutaneous tissue followed by softening. (*b*) A *focal* reaction at the site of the lesion, demonstrated by reactive changes, such as pain, hæmoptysis, increased sputum, and even by demonstrable alteration of physical signs. (*c*) A *general* or systemic reaction evidenced by fever, malaise, headache, and other indications of intoxication.

There are two chief methods of employing tuberculin for therapeutic purposes. In one of these it is given in increasing doses at intervals of from three to ten days. In this method reactions are expected, but they are kept within moderate degrees and are used to determine the amount and the spacing of successive doses. The object is to achieve a high degree of tuberculin tolerance. This is probably the more effective method in localised or surgical tuberculosis, but it is not devoid of danger in pulmonary cases. The other method is to start with very small doses and not to increase the dose till the patient is immune to that last given. In this method reactions are avoided as far as possible, and tuberculin sensitiveness is retained. This, in my opinion, is the only safe method in pulmonary cases. The doses are usually measured in milligrammes, as described by Koch, or in cubic centimetres of the original fluid supplied by the makers. Riviere and Morland suggest the use of the cubic millimetre as the measure of dosage, a method which has definite advantages. The preparation of dilutions is easily effected by means of a series of sterile amber-coloured glass bottles. Into each of these 9 c.cm. of a 0·8 sterile solution of sodium chloride in water containing 0·5 per cent. of phenol is placed. To the first of these 1 c.cm. of the original tuberculin solution is added. After thorough admixture 1 c.cm. of the resulting 1 in 10 dilution is put into the second giving a 1 in 100 dilution and so on. The sixth bottle will contain a dilution of 1 in a million and 1 c.cm. of this fluid would be equal to 0·001 c.mm. of the original fluid. Since the various tuberculins as supplied differ in strength this dose would be equivalent to 1/1000 mg. in the case of T., B.F., or A.F. 1/100,000 mg. of T.R. and 1/500,000 mg. of B.E. In the case of the second method of using tuberculin, these are suitable doses to commence with. Those who use the first method often commence with much larger doses, even as large as 0·5–1·0 c.mm. of the original fluid.

Tuberculin has been given by the mouth, by the rectum, by nasal insufflation, and by percutaneous inunction. The only reliable method is by hypodermic injection under ordinary aseptic precautions, although in gland cases good results are on record from inunction.

Partial Antigens and Defatted Vaccines.—The observations of Deycke and Much are of great interest and deserve more attention than they have received in this country. In the first instance by treating the bacilli with lactic acid they obtain two fractions: (1) referred to as M. Tb. L., which is soluble and contains the toxin partigen; (2) referred to as M. Tb. R., which is the residue. This they fraction further into three parts called respectively A., F., and N. A. represents the protein fraction, F. the fatty acid lipoid mixture, and N. the neutral fat, wax, fatty alcohol group.

[1] THE LANCET, 1924, i., 68.

In treatment they use either the mixture M. Tb. R. or the three partigens A., F., and N. either singly or in varying combinations. The method as employed by Much is somewhat complicated.[2] He first determines the patient's sensitiveness to M. Tb. R. and to A., F., and N., by intracutaneous tests. He then gives daily injections of A., F., and N. in the proportions these tests demonstrate to be necessary, increasing the dose gradually. Then after an interval of two or three weeks further tests are carried out and a further course of partigens in appropriate strength and proportions is given. Much claims that by this method the toxic factor M. Tb. L. is removed, whereas it is retained in the ordinary forms of tuberculin. More recently he has suggested that some of the beneficial effects of treatment by bacterial fractions are non-specific. His method has been extensively used in Germany by various observers, notably Klare, Altstaedt, and Ott. The statistics recorded are contradictory, some describing excellent results, others, like Ott, maintaining that the method has no advantages over tuberculin.

A recent modification of tuberculin, the "diaplyte vaccine" of Dreyer[3] has attracted a considerable amount of notice. Tubercle bacilli are treated with hot formalin and extracted with acetone repeatedly until they are non-acid fast or "defatted." They are then dried and ground with sterile salt solution. After dilution the suspension is centrifugalised, the clear fluid is pipetted off, and the amount of defatted bacillary substance in it is determined. From this stock suspension the doses of vaccine are prepared. This substance is still on its trial, and no definite statement can yet be made as to its value. It seems not to cause the local reaction seen with the ordinary forms of tuberculin.

Other forms of defatted tubercle vaccine have been prepared in Germany—e.g., Uhlenhuth used trichlorethylene for this purpose. As at present used tuberculin seems to have only a limited field of action in pulmonary cases. In general I am more convinced of its power for harm in pulmonary cases than of its usefulness, unless it is given cautiously under such conditions as I have just mentioned. In my experience its chief use has been in cases which have proceeded to arrest, but in whom there is still left a small amount of sputum containing tubercle bacilli. Cautious administration of small doses of B.E. or T.R. avoiding general or focal reactions, if possible, seems sometimes to dry up the sputum and to consolidate arrest. Although it has been recommended in febrile cases, its employment here seems to me irrational, if not dangerous. It is obvious that if it is given in doses sufficient to cause a severe focal reaction or a marked general reaction serious harm may ensue.

It is possible that some modification of the partigen treatment may prove of value in prevention and in treatment, but it must be confessed that at present the omens in regard to tuberculin treatment in pulmonary cases are not favourable.

(b) *Serum Treatment.*

Many attempts to afford some degree of passive immunity by serums have been made, but so far the results seem to have been even less encouraging than those of tuberculin. I find no less than 18 different serums mentioned. The earliest of these is that of Maragliano, first used in 1895 but now discarded. Marmorek's serum was introduced in 1903 and was tried in this country for a time. Recently, considerable notice has been given in the lay as well as in the medical press to the treatment proposed by Mr. Spahlinger, of Geneva. Full details of his method have not been published, and certain of the processes used in the preparation of his remedies have hitherto been kept secret. In so far as his treatment has been described by him, it consists of two forms, one of which, the antitoxin, is primarily intended for the acute cases, while the other involves active immunisation and is carried out by bacillary extracts or vaccines prepared by special processes. The "complete serum" is said to be both antitoxic and bacteriolytic, and is made up of several "partial serums" derived from horses treated with various toxins separated from the tubercle bacillus and its products, together with some serums obtained by inoculation of horses with certain secondary organisms. In the vaccine treatment four distinct vaccines are employed, each given in a separate course, the treatment being spread over several months. From various causes there has been great delay in preparing the complete serum, and restrictions and difficulties have been placed in the way of its widespread trial. A certain number of cases have been recorded apparently showing encouraging results, but sufficient data are not yet forthcoming to allow of a critical examination of the value of this treatment.

Quite recently Uhlenhuth has prepared a serum from cattle inoculated with large doses of avirulent tubercle bacilli, and this has been used by Czerny in 20 cases of severe tuberculosis of the lung with good results.

Spengler's I.K. treatment may here be mentioned. It is made from the red blood corpuscles of rabbits immunised with the *Bacillus humano-longus*. They are freed from protein and pigment and used in lactic acid suspension. This treatment now has very few adherents in this country.

Secondary Infections.

The rôle of secondary infections in this disease has been much discussed. It has been supposed that secondary organisms might play an important part in the breaking down of tuberculous lesions and in causing the symptoms associated with them. This is now generally regarded as incorrect, the tubercle bacillus being held responsible for all of the manifestations of the disease. Examination of the sputum of tuberculous patients often shows other organisms besides the tubercle bacillus, notably streptococci, pneumococci, staphylococci, Pfeiffer's bacillus, the *Micrococcus catarrhalis*, *Micrococcus tetragenus*, and Friedländer's bacillus. It is difficult to determine whether these, when present, play any active pathogenic rôle. Autogenous vaccines made from these frequently seem to have little effect. On the other hand, there are cases in which they appear to act almost dramatically. Dr. R. C. Wingfield has published an interesting note on this subject.[4] He points out that there is a type of case in which an autogenous vaccine is well worth trying. The patient generally has chronic disease, frequently rather extensive, and at intervals of a few weeks gets pyrexial attacks lasting four or five days, not apparently due to tuberculous auto-inoculation. Dr. Wingfield has usually found a streptococcus in these cases, and has had good results from vaccine treatment. He also suggests their trial in cases which "hang fire." I can confirm these observations and I also advise the use of vaccines in cases with marked catarrhal or bronchitic signs. The subject has recently been discussed at the French National Congress at Strasbourg[5] and seems worthy of further investigation.

Graduated Exercise and Graduated Labour.

This question may be considered here, since it has been suggested that some of the benefit of this mode of treatment is due to the effect it has upon the immunity processes by producing controlled auto-inoculation. The usual forms of exercise prescribed at sanatoria are walking and certain games. At all of them the walks can be graduated in length and at many of them also in the matter of level. Dr. Paterson's scheme of graduated labour, first introduced at Frimley and still followed there, was a useful advance. It had the great advantages that it employed the arms, gave interest and encouragement to the patients, and in

[2] Tubercle, 1921–2, ii., 25: also Intern. Centralblatt für die gesamte Tub. Forschung, 1920, 14.
[3] British Journal of Experimental Pathology, 1923, iv., 46.
[4] THE LANCET, 1923, i., 66.
[5] Ve Congrès National de la Tuberculose, Strasbourg, June 2nd–6th, 1923.

some cases served to prepare them better for return to work. The grades of labour are started when the patient has been able to walk up to six miles or more a day. The early grades consist of very light work with periods of rest, such as walking uphill, carrying small baskets, digging with a toy spade, and weeding. It is gradually increased to heavy work with a spade or pick. It cannot be too strongly insisted upon that this method of treatment requires most careful daily observation of the patient on the part of the doctor, and the strictest coöperation on the part of the patient. Over-exercise may be as dangerous as over-dosage with tuberculin, and may lead to active spread and prolonged fever. On the other hand, a small auto-inoculation may have beneficial results if it is at once recognised and the patient put to rest. Malaise, headache, pain, and increased cough or expectoration are subjective symptoms which should at once attract attention and suggest over-exercise, and this may be confirmed by rise of temperature, rapid pulse, and even by altered physical signs. Paterson recommends that if the resting temperature rises above 99° F. in men or 99·6° F. in women, they should at once be put to bed, especially if any of the indications just mentioned are also present. In spite of the criticisms recently directed to this method, I am convinced of its great value in suitable cases, if adequate care and judgment are used in its application.

Other Forms of Exercise.—Golf is often prescribed, allowing at first only a limited swing. In my opinion it is wiser not to allow golf until arrest is complete. Croquet and clock golf are permissible. When the disease is quiescent and the patient is able to take long walks, gentle horse-riding may be permissible. Care should be exercised in regard to games, not only because it is difficult to graduate the amount of exercise taken, but also because of the factors of competition and excitement, which are undesirable. In regard to cycling, rowing, and swimming, special caution is necessary and we should be sure that arrest is complete before permitting them.

CHEMOTHERAPY.

Attempts to find drugs which will have an action upon the tubercle bacillus comparable to that of salvarsan on the spirochæte of syphilis have not been successful. This is not surprising when we remember the resistant fatty and waxy envelope of the bacillus and the avascular character of the tubercles. At the same time, it can be proved that some drugs actually reach the bacillus in the lesions and the search for a true specific is still worth pursuing. Specific chemotherapy in the true Ehrlich sense is therefore as yet lacking, and we must content ourselves with examining whether there is any evidence that any of the so-called "false specifics" exert any direct or indirect beneficial effect upon patients suffering with the disease—in other words, drug therapy rather than chemotherapy.

The Antiseptic Group.

Creosote and Its Derivatives.—Creosote was first suggested in this disease by Reichenbach as long ago as 1830. The experimental evidence of its value is not very convincing. It has only a weak action in inhibiting the growth of the tubercle bacillus, and it has no specific action on this organism, nor does it seem to exert any beneficial influence upon guinea-pigs infected with tubercle. The chief evidence of its usefulness is clinical, and it is significant that whereas it was formerly employed almost as a routine treatment, its use is now more restricted. It seems to be of value in cases of chronic fibroid disease with copious expectoration, in patients with a secondary infection or with chronic bronchitis, and in some early cases with dyspepsia and intestinal fermentation. When given in too large doses, or for too long a period, it may disturb digestion, causing pain, discomfort, and eructations, and it may produce hæmoptysis. According to Dr. Fishberg, it may lead to symptoms comparable to a tuberculin reaction from its effect upon the focal lesions during excretion by the bronchi. It is important that a pure beechwood creosote should be employed. It is best given in capsules or perles, starting with 2 minims after food three times a day, increasing gradually up to 6 minims. It is sometimes given with syrup or balsams, but its hot unpleasant taste renders it disagreeable to most patients. It should not be persisted in if it causes any discomfort or any unpleasant symptoms. The numerous derivatives and compounds of creosote, such as guaiacol (1–3 minims), guaiacol carbonate (10–30 gr.), creosotal (creosote carbonate) 5–10 minims, guaiacol cinnamate (styracol) 5–15 gr., potassium guaiacol sulphonate (thiocol) 5–15 gr., have the same indications and the same actions as creosote. They differ chiefly from it in cost and in taste.

Ichthyol.—Ichthyol (2–5 minims three times a day before meals in milk or water), and its derivatives ichtboform, ichthyol salicylate, and ichthalbin, has been recommended for the same types of cases as creosote and on similar evidence. It is apparently non-toxic and less irritating than creosote. Other antiseptics which have been suggested are phenol, cyllin, and urotropin. The evidence of their value, except as acting on bacteria in the digestive and urinary tracts, is slender.

Iodine.—Iodine requires more detailed consideration if for no other reason than the fact that it has been used so long empirically as a remedy in this disease. The experimental study of its action lends no support to the view that it exerts any specific effect upon the bacillus. It can be shown to reach the tubercles, and it is said to increase lymphocytosis. It also increases the bronchial secretion, and it may induce changes in tuberculous lesions comparable to those produced by tuberculin. It should, therefore, not be used as a routine, or indiscriminately. I have used it considerably and I think with benefit, chiefly in cases of the chronic fibroid type with associated chronic bronchitis, and in some of more active type with slight persistent fever. It is best given as the weak tincture in milk after meals, beginning with one drop and increasing slowly up to 20 drops or more. It should be stopped if it causes any unpleasant symptoms, either as regards the lungs or the digestive system. Curle's "nascent" or intensive iodine treatment may be tried, but is, I think, more likely to disturb digestion. Thirty grains of potassium iodide are given after breakfast in at least half a pint of water to which some potassium bicarbonate may also be added. Chlorine water flavoured with lemonade is given during the day up to 3 to 5 oz.

Dye-treatments.—Various dyes, including methylene-blue, have been used experimentally in animals, owing to the brilliant results obtained by their use in some parasitic infections. An interesting observation[6] has emerged from this work, since it appears that fat-soluble dyes do not easily penetrate tubercle bacilli, while some water-soluble dyes like methylene-blue do so, and that the bacilli are less susceptible to fat-soluble antiseptics, and more susceptible to water-soluble than bacteria with less fat. There is not at present enough evidence of the value of dye-treatment to suggest its use in man.

Cod-liver Oil and Sodium Morrhuate.—Cod-liver oil has long been credited with a beneficial action in this disease, and large quantities, even up to 4 oz. a day, have been given by some French physicians. In this country smaller quantities are usually employed, and it is often given in emulsion or in association with iron or with hypophosphites. Its effects have been variously attributed to its nutritive value, to its vitamin content, and to a possible specific effect upon the bacillus. Sir Leonard Rogers, stimulated by the effects of chaulmoogra oil and the non-saturated fatty acids obtainable from it in leprosy, prepared from cod-liver oil a substance, sodium morrhuate, for use in the treatment of tuberculous disease. It has been shown that chaulmoogra oil contains chaulmoogric and hypnocarpic acids, which are 100 times more bactericidal for the acid-fast bacilli than phenol. Sodium morrhuate has been employed in the treatment of pulmonary tuberculosis, and good results have been put on record by Muir, Knowles, and Davies. Febrile reactions may occur after its use, and occasionally slight hæmoptysis. It is suggested that the effects are comparable to those of tuberculin, and that the bacilli found in sputum after its use show deficient staining and a granular appearance. It is best given hypodermically in the form of a 3 per cent. watery solution, to which half per cent. carbolic acid is added. Small doses should be given two or three times a week, at first 0·1 c.cm. to 0·5 c.cm., increasing up to 1·5 c.cm., watching carefully for reactions. I have used this substance in a few cases, in some with apparent benefit. Sir Leonard Rogers has himself counselled caution in its use, and further trial of its effects both in animals and in man are necessary before its value can be finally assured.

Gomenol.—Gomenol, a distillate from *Melaleuca viridiflora*, has been used in France. It is given subcutaneously in 10 per cent. solution in oil, gradually increasing from 2 c.cm. up to 10 c.cm., and even 50 c.cm. It is given daily for several doses, then a few days' interval is allowed and a further series is given.

[6] De Witt and Sherman: Journal Infect. Dis., 1914, xv., 245.

Pneumosan.—Pneumosan (amyl-thio-trimethylamine), in doses of 4 to 10 minims intramuscularly, had a vogue for a time, but is now rarely used in this country.

Garlic.—Garlic and allyl compounds were recommended years ago by Dr. Vivian Poore, and have been employed again recently. Their action seems comparable to that of the creosote series, and there is no evidence of any specific action.

Hypophosphites and Glycerophosphates.—These have been recommended as general "tonics" in this disease, and are frequently given in combination with certain metals on the basis of the remineralisation theory to which I shall refer later.

Cinnamates.—Landerer recommended cinnamic acid and its salts in the disease. He claimed that it increased leucocytes. Cinnamate of soda is the form which has been used chiefly. Good results have been recorded by various French and Spanish physicians. It is given subcutaneously in doses up to 10 cg. It is now stated to have a hæmolytic action and therefore not recommended.

Metallic and Mineral Substances.—Arsenic seems to have been used in this disease from Greek and Roman times. There is no evidence of any direct action upon the bacilli or the diseased tissues. Any action it possesses in this disease is probably due to its effects upon metabolism. It should be used with care and not as a routine. It may be given as arsenious acid in pill, sodium arseniate, liquor arsenicalis, arrhenal, or cacodylate of soda. The last named is a convenient form. It is given by hypodermic injection in doses of $\frac{1}{4}$ to $\frac{1}{2}$ gr. daily or every other day for about a fortnight, then an interval is allowed and then other courses are given in succession. Salvarsan has also been given with benefit in cases of syphilitics with pulmonary tuberculosis. It is not devoid of risk in other patients.

Mercury Salts.—Mercury succinimide has been recommended by Barton Wright in doses of 1/5th gr. in 10 minims of water given hypodermically every other day till 30 doses have been given. It is said to be specially useful in syphilitic patients. Recent experimental work in animals by De Witt seems to show that mercury compounds exert a favourable action on the disease, and suggest the need for further work on this subject.

Calcium Salts.—Certain French authorities, notably MM. Ferrier and Robin, have attached great importance to a supposed demineralisation in tuberculosis. Calcium salts have been repeatedly used in the treatment of this disease, partly because of the calcification which occurs as one method of cure, and partly because of the legend that those who work in lime dust do not contract the disease. Robin maintained that tuberculosis was associated with an increase, and an alteration of the respiratory exchanges and a demineralisation of the body. He gave fresh bone powder with carbonate of magnesium and of calcium, together with lactose and fluoride and silicate of calcium. Recent work has not confirmed Robin's views, though calcium, especially in the form of collosol calcium, has been used by Prest and others. Considerable claims have been made by Prest as to its value, but some other observers have not been so fortunate. It has the merit of being harmless, except in very large doses. Recently G. Hartwick-Borrman reports favourably of a trial in 600 cases of a comparatively salt-free diet with a teaspoonful before breakfast of a solution of 30 parts of calcium chloride, 60 parts of potassium acetate in 285 parts of water. It should be given in a glassful of warm water, but should be withheld if renal complications are present.

Silica.—Since silica is found in all tissues and more abundantly in connective tissue, silica preparations have been recommended in the hope that they would induce fibrosis. There seems very little evidence, either experimental or clinical of its value.

Colloidal Metals.—Other metals in colloidal form have been recommended in this disease, notably silver, gold, copper, and brass. Although good results have been recorded from some of them, there is little real evidence of their beneficial action.

Organotherapy.—Various organic extracts have from time to time been suggested, including extracts of lung tissue, lymphatic glands, both tuberculous and normal, spleen, and pituitary. Muscle extract or meat juice has also been employed. The fact that most, if not all, of these have been discarded is the best evidence that they are of no real value.

Treatment by Inhalation and by Intra-tracheal Medication.

Inhalations have been used since very early times. They were recommended for laryngeal cases especially by Dr. Coghill and Dr. Burney Yeo, who introduced convenient forms of oro-nasal respirators for the purpose.

Dr. D. B. Lees recommended more or less continuous inhalations, and claimed to have seen cures by this method. He used phenol 2 parts, creosote 2 parts, spirits of chloroform 2 parts, spirits of ether 1 part, and tincture of iodine 1 part. This sometimes causes irritation of the air passages and even slight hæmoptysis, and I have found the formula in use at the Brompton Hospital preferable—viz., menthol 4 parts, oil of cinnamon 3 parts, oil of lemon 4 parts, creosote 20 parts, oil of pine 10 parts, and spirits of chloroform 10 parts. Five to eight drops of this per hour are put on the sponge of the respirator. Although some patients complain of discomfort and difficulty in breathing from the use of a respirator, I have found that the majority find it helpful in lessening cough and expectoration. It is specially useful in laryngeal cases. Kuhn's mask was introduced in 1906. It was devised to induce passive venous congestion of the lung on Bier's principle. It seems to have followed many other ingenious treatments, based on theoretical considerations, into the limbo of the disused. Intratracheal injections have been employed, that most favoured being a mixture of menthol, olive oil, and guaiacol. It is chiefly of use in cases with bronchiectasis, or with offensive sputum, a strikingly uncommon event in this disease.

PHYSICAL METHODS OF TREATMENT.

Heliotherapy.—The striking success of the sun cure of Rollier in surgical tuberculosis has naturally directed attention to its use in the pulmonary forms of the disease.

Rollier admits that great care is necessary in its application in these, but claims that in suitable cases it can be of great value. He suggests that on the first day the feet only should be exposed for two or three minutes, and that the rest of the body should be gradually acclimatised to the sun's rays before the chest is exposed. He also advises that in hot weather, exposure should be limited to the early morning sun. It is generally allowed that if the skin does not pigment after exposure to the sun's rays, the treatment should be stopped. Although some observers have recorded good results from heliotherapy, especially in children, the majority advise against it. It seems not infrequently to cause a rise of temperature, hæmoptysis, and other manifestations of auto-inoculation. It is possible, as has been suggested, that different types of pulmonary disease react in different ways. No case with fever should be submitted to this form of treatment.

Artificial Sunlight.—Exposure to the rays from the quartz lamp has been tried, but unpleasant effects, like those from sun treatment, seem to occur not infrequently in pulmonary cases. Ultra-violet rays have also been employed on the supposition that the beneficial effects of sunlight are due to them.

X Ray Treatment.—This has been tried more especially in glandular tuberculosis, including disease of the bronchial glands. It is often employed as an addition to other forms of treatment, as e.g., by Much, in association with his partigens.

Bacmeister and Kupferle have claimed that radiotherapy can assist in the cicatrisation of tuberculous lesion without destroying the bacilli. They regard it as useless in acute caseous and rapidly developing lesions. The chest is mapped out into areas and carefully measured doses are given. Most observers agree that the tubercle bacillus is not sensitive to the X rays, and that the effects obtained are due either to the changes induced in the tissues irradiated, or to reactive processes produced in the hæmopoietic organs. The chief exponent of the latter view is Manoukhin.[7] He gives regulated doses of X rays of a definite strength and hardness, filtered through 1 mm. of aluminium and applied to the spleen exclusively from the front and back, not from the side, and in such a way that no rays reach the liver. He believes that the beneficial results are due to the leucocytolysis induced, and maintains that the curve of the specific antibodies follows that of the destruction of the white corpuscles. In the first stage of the disease he gives eight to ten applications, in the second 12 to 15, and in the third stage two series of 12 to 15, with an interval of two or three months between them. Trémolieres and Columbian have recorded good results by a similar process, but in addition they apply the rays to some of the long bones. They explain the action of the rays in a different way to Manoukhin, who criticises their technique and their views. These methods seem at least to be worth a cautious trial.

[7] THE LANCET, 1921, i., 685; and Presse Médicale, July 18th, 1923.

It must be confessed that some, if not all, of the much vaunted remedies I have mentioned make but a sorry display when examined critically and experimentally, while most of them fail us in the cases in which we most need help—namely, in those with active progressive disease with fever not controlled by absolute rest. At the same time, a very little may sometimes turn the scale, and provided we are convinced that a treatment does not entail risks, it may be well to give it a careful trial, if only for the encouragement it affords to the patient and the opportunity it allows to the practitioner of giving regular supervision to the details of the patient's daily routine. There is much to be said for the suggestion of M. L. Renon that we should utilise the "normal coefficient of improvement" by employing in sequence various forms of treatment for short periods.

SYMPTOMATIC AND PALLIATIVE TREATMENTS.

In a disease which may take such a long and varied course and in which such distressing symptoms and complications, often harmful in themselves, are liable to occur, palliative treatment may be of the greatest value. Few cases require more skill and resource in treatment than one of chronic progressive pulmonary tuberculosis. We may now consider the treatment of some of these symptoms and complications.

Cough.—An ineffective cough is unnecessary and harmful, and it should be checked. This can often be done by instructing the patient as to the risks of such a cough, and teaching him to restrain it as insisted on by Dettweiler and others. Where it is due to some source of irritation, such as pharyngitis, granular pharynx, some nasal condition or irritation of the base of the tongue, these should be dealt with by appropriate means. Mandl's iodine-glycerine pigment is useful, or some form of sedative or antiseptic spray or nebula. A laryngeal cough is often troublesome, painful, and associated with copious frothy expectoration. Antiseptic inhalations and rest to the voice often help in this case. Simple demulcent lozenges or domestic remedies may be given, care being taken to avoid anything likely to disturb digestion. The sputum accumulated during the night may be viscid and cause sickness after cough, which is commoner in left-sided cases. A cup of hot milk and water or weak tea often relieves this. If this fails a mixture containing 10 gr. of sodium bicarbonate, 3 gr. of sodium chloride, spirits of chloroform 5 to 10 minims, and water to the ounce often gives relief, especially if given with hot water. For nocturnal cough disturbing the patient's rest, some form of sedative is frequently necessary for a time, and of these heroin 1/24–1/12 gr. in a simple linctus, syrup of codein, or collosol bromoform are the most useful. An effective cough should not otherwise be interfered with. When expectoration is copious creosote or some of its derivatives may sometimes be helpful, especially if there is a factor of chronic bronchitis. If expectoration is offensive, antiseptic inhalations may be ordered and creosote or garlic given internally.

Dyspnœa.—This may be due to the extent of lung involved, to mechanical conditions such as pleural effusion, or in the late stages to cardiac enfeeblement. In chronic fibroid cases dyspnœa is often more marked in cold, wintry weather. Rest is often of great value in such cases. If there is a mechanical cause for the dyspnœa, such as an effusion, rest, and if necessary paracentesis, may give relief. Dyspnœa due to extent of lesion and to heart failure is usually terminal, and can only be palliated by rest, oxygen, and cardiac tonics.

Fever.—The treatment of fever is in the first instance absolute rest, in the hope of limiting and eventually controlling auto-inoculations. Where rest fails it is necessary to consider other measures, such as change of room, living and sleeping in a shelter so as to get more air may be tried. Careful hydrotherapy in the form of sponging or packs may help to relieve the discomforts associated with it, but not to deal with the cause. Similarly antipyretic drugs are purely palliative in their effects, and should be avoided if possible. Those chiefly employed are phenacetin, antipyrin, aspirin, quinine, cryogenin, and maretin. The sweating associated with their action as a rule brings nearly as much discomfort as the actual fever. I very rarely use them. When fever persists in spite of rest it is usually wise to consider whether artificial pneumothorax should be tried.

Night Sweating.—These are much less common since the importance of fresh air and free ventilation have been recognised. Rufenacht Walters says "they are nearly always a sign of hygienic mismanagement." This statement is, perhaps, a little too sweeping. When they occur, careful inquiry should be made as to the ventilation of the bedroom, the character of the mattress, and the amount of bed-clothes. Sometimes it is also helpful to sponge the patient before settling him down for the night with hot or tepid water, to which toilet vinegar has been added, and to have a second suit of night clothes ready warmed to put on after the patient has been dried. Paterson[8] recommends placing a grass mat over the mattress and under the sheet on which the patient lies, or else sleeping on canvas without a mattress in cases where the measures first recommended fail. Various drugs were formerly given to relieve this symptom, notably zinc oxide, belladonna, atropine, strychnine, picrotoxin, and agaricin. They are now rarely used, since in most cases they are unnecessary, and our object is to avoid this symptom, not to mask it.

Hæmoptysis.—If there is only streaking of the sputum no treatment is necessary. It it be small in amount—e.g., 2 or 3 oz., rest, some saline aperient, and a dose of bromide to allay the patient's fears may be all that is necessary. In more severe hæmorrhage the patient should be put to bed, lying on his back or towards the affected side, and if it be very profuse he should lie with the head low so that suffocation may be prevented by allowing the rush of blood to escape. The tendency nowadays is to keep the patient less strictly quiet, owing to the observations of Bang that movement has little to do with hæmoptysis, and morphine is less commonly used as a routine treatment on the ground that it lessens cough and tends to cause the effused blood to remain in the lungs and to spread the disease more widely. In a very nervous patient a small dose of morphine, heroin, or codein may, however, do good by allaying anxiety, lessening restlessness, and thus slowing the heart-beat. Nitrite of amyl, 3–5 minims, as an inhalation is worth a trial. Calcium lactate or calcium chloride, 10 gr. in water by the mouth every two to four hours for four doses and then three times a day for two or three days, seems sometimes to be helpful. Calcium chloride can also be given intravenously in doses of 2 c.cm. of a 15 per cent. solution. It has also been given intramuscularly, but for this purpose it requires greater dilution. Where these measures fail, sterile horse serum, "coagulose," and hæmostatic serum may be tried. In cases where repeated small leaks occur, daily hypodermic injections of emetine hydrochloride, ½ gr., may be used. A dose of 5 to 15 gr. of salt by the mouth is said to increase coagulability. A saline purge, preferably sodium sulphate, should be given unless the bowels are freely open. Turpentine has been recommended, and Dr. Jane Walker advises inhalation of this substance at the commencement of the hæmorrhage. The application of ice to the chest is better avoided and the sucking of ice should be restricted to a small amount. Adrenalin and ergot, formerly used by some physicians, should not be employed. The diet should not be greatly restricted, but the food should be given cool, and no alcohol should be permitted. In cases with prolonged or frequently repeated severe hæmoptysis, artificial pneumothorax must be considered, but it requires great care if it be decided to do it while the hæmorrhage is in progress.

Pain.—Pain in the active stages of the disease is usually due to pleurisy. It should be treated by rest and local application of counter-irritants or anodynes, such as blisters, an iodine paint, wintergreen ointment, or belladonna. Strapping the affected side is sometimes recommended, but may cause dyspnœa. In arresting cases pain is sometimes present without pleural signs, and may be due to contraction of pleural adhesions. It may be treated on similar lines.

Digestive System.—Symptoms due to disturbances of digestion are very common. Anorexia is often troublesome, and requires very careful treatment, such as changes in diet and in routine. Dyspeptic symptoms should be investigated and treated on recognised lines by acids or alkalies, bitters and ferments such as takadiastase, malt extracts, pepsin, or papain. Hypochlorhydria is said to occur, and may be a cause of diarrhœa. Dilute hydrochloric acid may then be given in doses of 10 to 30 minims. Dyspepsia may be due to excess of milk or other fatty foods, or to monotony of diet. Diarrhœa may occur apart from tuberculous enteritis, and should be treated by avoiding foods with coarse residues and by giving bismuth, chalk, opium, tannic acid preparations, and salol or other intestinal antiseptics. Constipation requires treatment, especially during the period of rest in bed. It can usually be controlled by diet and by simple laxatives.

Insomnia may be due to too much sleep in the daytime, which can often be obviated by the patient occupying a different bed or room during the day to that used at night. It may be due to cough, pain, or diarrhœa, which should be treated by the appropriate measures. Hypnotics should only be given if other measures fail.

[8] THE LANCET, 1922, ii., 725.

MANAGEMENT OF ADVANCED CASES.

Advanced cases require special care, and where possible they should be treated in special institutions or in nursing homes. Their management is largely a question of nursing, and the treatment of symptoms and complications. Unfortunately they are the most difficult cases to find accommodation for. They are certainly unsuitable for treatment at home in small homes because it is difficult to secure adequate precautions as to infection and to afford proper nursing, food, and treatment. On the other hand, such patients are often averse to leaving home, even when special accommodation is available for them. The duty of the practitioner in charge of such a case at home is a responsible one, because he should be sure that all precautions are taken, and that young children do not come in any contact with the patient. He must also give advice in regard to the disinfection of the linen and utensils used by the patient.

The complications of this disease are numerous and require special treatment and nursing. Among the more important of these are: Tuberculous laryngitis, enteritis, spontaneous pneumothorax, pleurisy with effusion, empyema, peritonitis, and meningitis.

AFTER-CARE, COLONIES, SETTLEMENTS, AND VOCATIONAL TRAINING.

These are all aspects of the tuberculosis problem which are being dealt with by the Ministry of Health, either directly or by the aid of voluntary and charitable agencies. One of the great difficulties in the management of these cases is to map out the best course for the patient when he leaves the sanatorium, especially when he is not able to remain until arrest is complete and consolidated. To return to work under these circumstances and under the conditions which preceded breakdown is generally to court disaster; often in a very short space of time. On the other hand, it is now recognised that to advise a town worker to seek an outdoor or country occupation is usually impracticable and uneconomic. If possible he should return to his former work under better conditions and with a better knowledge of how to live and work, unless that occupation is obviously unsuitable or dangerous. The difficulty is the period between active treatment and full working capacity; when the patient may be able to do some work and yet not able to earn enough to support himself, let alone his family. It is to deal with this aspect of the problem that after-care committees are being encouraged, and that colonies and settlements are being established. The work of Dr. P. C. Varrier-Jones at Papworth Colony is recognised as a pioneer effort of the utmost importance, and Sir James Kingston Fowler, in his interesting and suggestive little book on the Problems of Tuberculosis, accords him a high meed of praise and admiration. This book also includes a suggested scheme for the further organisation and coördination of institutions from the sanatorium to the settlement. The Ministry of Health are dealing with this question in a sympathetic spirit, but it must not be forgotten that there are great difficulties—financial, administrative, and practical. The training of men to new work, their relation to the labour market and to the trade-unions, and the disposal of the products of their labour are all matters requiring organisation and adjustment.

The general practitioner and the physician are also concerned in this question, since they often have to advise patients for whom no such arrangements are forthcoming. The day is past when we can talk vaguely of farming, forestry, market gardening, and chicken rearing as the occupation for arrested lung patients. We have to advise them how they can best earn enough to support themselves under conditions favourable to the maintenance of their health when arrest has been attained. We may have to inquire closely into the nature and conditions of the occupations of our patients, and to advise after a careful consideration of all the circumstances.

BILHARZIAL PAPILLOMATOSIS OF THE RECTUM.

BY ROBERT V. DOLBEY, M.S. LOND., F.R.C.S. ENG.,
DIRECTOR OF THE SURGICAL UNIT, SURGEON TO THE KASR-EL-AINY HOSPITAL, CAIRO;
AND
IBRAHIM FAHMY, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

THE incidence of bilharziasis, from which disease it is estimated that at least 75 per cent. of the Egyptian population have at one time or another suffered, varies in the different districts of Upper and Lower Egypt. The reason for this is at present obscure; it may be the change from the basin or flood irrigation of Upper Egypt to the perennial irrigation of Lower Egypt, or the nature of the intermediate host of the parasite, that is responsible. The type of bilharzia, with terminal spined ova, affecting the urinary system from Upper Egypt, seems to be associated with a less severe type of disease—disease of the bladder, ureters, and renal pelvis in particular—than in the perennial irrigation areas of Lower Egypt. There are regions in the Delta also where simple affections of the bladder alone are most common, and other regions, again, where disease of the ureters and renal pelvis is the rule.

Various Types of Disease.

The district of the Fayoum, one of the oases of the western Desert, is, however, particularly associated with the development of intestinal bilharziasis (*B. mansoni*—the lateral spined ova). The chief seat of this disease is in the rectum, and it is characterised by the formation of numerous papillomata of sizes varying from an orange to a pea. A typical appearance is shown in the appended figure. The lateral spined ova are found within the papillomata themselves and in the submucous layer of the bowel. Bilharziasis of the colon as a whole exists in four types: (1) a simple congestive thickening of the mucous membrane; (2) congestive thickening with papillomata; (3) tumour masses in and around the colon or small intestine with or without local papillomata, and sometimes associated with deposits studded throughout the peritoneum and mesentery (Madden and Ferguson).[1] Polypi of the cæcum are not uncommonly the cause of chronic intussusception, in which the apex of the invaginating bowel is formed by the polypus itself. Ferguson describes a stricture of the large bowel produced by an adult worm encircling the gut and depositing its eggs around the lumen.

Treatment.

The symptoms of rectal bilharziasis are constant tenesmus, with the passage of blood and mucus, whereby the patients are condemned to a life of utter misery, progressive anæmia, and emaciation. Treatment by tartar emetic is successful in destroying the living ova, but the papillomata and the consequent symptoms continue. Local operative procedure by removal of the isolated papillomata by the knife or diathermy is unsuccessful. The papillomata always recur. Injections of carbolic acid 1–20, or various chemical agents, into the bases of the papillomata are equally unsuccessful. The only complete, thorough and permanent cure is obtained by the excision of the whole tube of mucous membrane of the rectum. This has been performed eight times by us, six times by one of us (I. F.), and twice by the other (R. V. D.). The astonishing ease with which the whole unbroken tube of mucous membrane can be excised is most remarkable. Lengths of 12, 15, and 17 in. have been removed by one of us (I. F.),

[1] Madden, F. C.: Surgery of Egypt.

and lengths of 14½ and 9 in. by the other (R. V. D.). A circular incision is made at the junction of skin and anal mucous membrane. Blunt dissection separates the external sphincter muscle without division of its fibres. Two inches of the tube of anal mucous membrane are then easily withdrawn, and the opening of this tube closed by forceps. The attachment of the levator ani forms the next and only other difficulty. When once this muscle is separated by blunt dissection the mucous tube may be loosened by the gloved finger and withdrawn with the greatest ease until the upper limit of the papillomata has been reached.

This operation was first practised by one of us (I. F.) in 1919 and described in a preliminary note.[2] The operation was conceived as a cure for simple prolapse of the rectum when a more complete examination revealed papillomata in the rectum higher up. The presence of the prolapse facilitated

Congestive thickening of rectum with papillomata.
A = Anal margin.

the dissection of the mucous tube. The succeeding seven cases had no prolapse. Two of the cases operated on by one of us (I. F.) were children of 10 and 12 years; the results were even more satisfactory than in the adults.

In the majority of cases the papillomata are limited to the rectum proper and the sigmoid colon is free. The mucous tube is withdrawn—2 in. or so further than the limit of the papillomata, to ensure that there shall be no tension on the tube—and excised, and the edges are then sutured to the margin of the skin and external sphincter muscle.

Recovery is usually uneventful. There is little tendency to retraction of this tube provided that precautions have been taken to avoid tension. Healing takes place as a rule with only a ring of granulations at the anal margin. Control of the anal outlet by the external sphincter muscle is regained in a week. Healing by first intention should not be expected; and dilatation of the sphincter should be practised early to avoid a stricture.

Anatomical Results.

Pathological examination of the mucous tube removed shows that it is entirely composed of mucous and submucous tissue. The muscular coat of the rectum is not removed by this operation. No opportunities have occurred as yet for examination of such cases by autopsy. An operation, however, upon the cadaver performed by one of our colleagues, Mr. A. W. Mooro, disclosed the fact that the sigmoid-rectal junction is brought down close to the anal orifice. On opening the abdomen the rectum was "concertinaed" but there was no intussusception. The musculo-peritoneal tube was very thin. The mucous tube, 15 in. in this case, had been removed from 9 in. of the rectum; thus 6 in. of the mucous tube had been removed at the expense of the redundant folds of rectal mucous membrane. Subsequent examination of our cases with a sigmoidoscope shows a straight tube of mucous membrane without any folds.

Selection of Cases.

A note of warning in the selection of cases for operation should be sounded. The operation is accompanied by some shock, and sometimes by considerable hæmorrhage during the separation of the levator ani attachments. We provide ourselves with long artery forceps, and never operate upon severely anæmic patients, particularly those with a hæmoglobin index of 45 per cent. or under. In the very anæmic and debilitated we have performed a preliminary blood transfusion to restore the hæmoglobin. The operation in Egypt is best performed under stovaine anæsthesia; but some discomfort is complained of when the root of the sigmoid mesentery is pulled upon during the removal of the last inch or two of the mucous tube.

While seven of these cases have been perfectly successful it must be recorded that, in the first case of this series, there was such tension left upon the mucous tube that the sutures gave way and retraction of the tube took place to the extent of 3 in. An intractable stricture developed which necessitated the weekly use of a dilator. The subsequent state of this patient is, however, infinitely to be preferred to the previous condition of tenesmus and progressive anæmia which had rendered his life an utter misery.

In the cases where the papillomatous condition can be seen by the sigmoidoscope extending up to the descending colon, the removal of the rectal portion of mucous membrane, always the most markedly affected region, is sufficient to relieve the urgent symptoms. Isolated bilharzial polypi of the descending colon, the splenic flexure, and the transverse colon may exist with no symptoms but those of a mild chronic diarrhœa.

A NOTE ON POST-OPERATIVE INSANITY.

BY A. J. COKKINIS, M.B., B.S. LOND., F.R.C.S. ENG.

IN view of the recent discussion at the Royal Society of Medicine on post-operative and puerperal insanity,[1] I feel impelled to make this clinical contribution in the hope of elucidating one or two points in a condition which is obscure and often puzzling. I have a case of post-operative insanity under my care now, and as this contribution is largely based on this case I propose to describe it at length.

The patient is a married woman, aged 60, of good social position and in comfortable circumstances. Prior to the

[1] THE LANCET, Jan. 19th, 1924, p. 129.

operation she had never exhibited the slightest sign of mental instability, but possessed, on the contrary, a particularly steady and reliable intellect. Although she was one of a numerous family, there have been no cases of mental trouble among her relations. She had an abdominal operation ten years ago from which her recovery was uneventful.

Operation.—In October, 1923, her nasal septum was resected under a general anæsthetic. She took the anæsthetic badly, her circulation failed, and at one stage artificial respiration had to be resorted to. She did not recover consciousness for over 24 hours, the immediate post-operative condition being one of profound coma.

Onset of Confusional Insanity.—She then gradually recovered consciousness, but passed on to a condition of acute confusional insanity, without the intervention of a lucid interval. She was noisy, rather violent, did not recognise her husband or her children, had completely lost her memory, and was extremely confused and agitated.

Development of Chronic Dementia.—The acute condition lasted three days and she then passed, by a rather sudden transition, to a state of chronic paranoic dementia, in which she has remained for three months. Her present mental condition can be best described as a complete dissociation of ideas. She has rare intervals of comparative lucidity, during which she seems fairly rational, provided the conversation is kept at a very simple level; at all other times she is totally irrational.

Delusions.—She is full of the most extraordinary delusions, which change and swing about like the pattern of a kaleidoscope. Thus, one moment she attributes her condition to a dog-bite, the next to a cat-bite (!), and the next to worms eating into her wrists. Within two minutes her Christmas dinner passes through the phases of turkey, rabbit, beef, lamb, chicken, ham, and other things. In the same sentence she gives the date of her birth as 1891 and 1999, and she has completely lost the ability to do the simplest arithmetical sums. Her daughter is her sister and her sister is her daughter; she is pregnant at one visit, burying her baby at the next, and so on. Her delusions are seldom systematised, but her entire mental life is strung on delusions, which vary from one minute to the next, and to explain which she invents other and more extravagant delusions. Her sensation and perception are good, but memory she has none. Neurological examination reveals nothing abnormal and her general health is very good.

Quite recently I had the benefit of seeing the patient in consultation with Dr. R. H. Cole. He expressed the opinion that the case was as unique as it was instructive, and that it could not be explained away as an instance of a purely functional psychosis following operation. The clinical picture and the absence of a family or pre-operative personal mental history, coupled with the sudden onset of mental trouble immediately after operation, point to an organic basis for the mental disorder.

The clinical condition strongly suggests a definite interruption of idea-association impulses, such as might take place as a result of minute focal hæmorrhages or thromboses destroying certain association fibres in what are known as the silent areas of the brain. This ætiological hypothesis is strengthened by the possibility of vascular trauma in the cardiac and respiratory trouble experienced during the anæsthesia, and by the prolonged period of coma after the operation.

Such an ætiological hypothesis appears worthy of consideration in certain cases of post-operative or post-traumatic insanity, where gross brain injury and psychical or toxic causes are absent, and where the mental trouble asserts itself immediately after the operation or injury. Should the foci of vascular lesions implicate the comparatively small section of brain matter of neurological importance (motor area, visual centre, &c.) this would be demonstrated by a neurological examination. But in that great field of brain matter known as "association areas" a lesion is incapable of neurological proof, and we are perhaps too prone to make use of purely functional arguments in attempting to explain the ætiology of traumatic or post-operative insanity which is not associated with physical signs of nervous injury.

I am greatly indebted to Dr. Cole for his help in solving the problem presented by this case, and for his kind permission to publish it.

Ilford, Essex.

A SIMPLE METHOD OF PREPARING HANDS AND GLOVES FOR OPERATION.*

BY G. W. THEOBALD, M.B., B.CH. CAMB.,
ASSISTANT MASTER, ROTUNDA HOSPITAL, DUBLIN;

AND

J. W. BIGGER, M.D. DUB., F.R.C.P. IREL.,
LECTURER IN BACTERIOLOGY, TRINITY COLLEGE, DUBLIN.

PART I.—(G. W. T.).

OWING to the very wide variations in the directions given by the different authorities as to how the hands should be prepared for surgical operations an attempt has been made to formulate a safe and simple method. The object of this paper is to contend (1) that rubber gloves may be easily sterilised without resort to heat; (2) that it is illogical and unnecessary to wash socially clean hands before operating; (3) to advocate the doctrine of "abstention."

Gloves are usually sterilised by boiling or the autoclave. The boiling of gloves is quite satisfactory and easily carried out, but it slowly destroys the elasticity of the glove, so that it soon ceases to fit. When a puncture occurs in such a glove a definite hole results, which allows of the escape of fluid. If the gloves have been put on out of antiseptic the fluid which escapes at first will be harmless. But antiseptic in contact with the skin soon gets destroyed, and the puncture permits the escape of an emulsion of bacteria. The second method necessitates the use of an autoclave, and is only available to those on the staff of a hospital. So hard is the steam on the gloves that they perish after being used three or four times. These gloves lose their elasticity after being sterilised once, and an ordinary needle-prick then makes a considerable hole.

As a result of frequent experiment we claim that however a smooth rubber glove be contaminated it can always be made sterile by a simple washing with soap and water, followed by a thorough rinsing in antiseptic. The gloves should always be treated on the hands and fit well. They should be washed for one minute with soap and water, rinsed in water, and then rubbed well together in a 1-1000 solution of biniodide of mercury. If dried blood, vernix caseosa, or similar material is on the gloves they should be scrubbed with an ordinary scrub brush till clean, rinsed, and treated with antiseptic. A glove so treated retains its elasticity for two months or more, so that an ordinary needle puncture is so small that it is only with difficulty that fluid can be squeezed through it. It is perfectly obvious that if it could be guaranteed that the glove would not be punctured it would not matter how dirty the hands underneath were. Unfortunately no such guarantee can be given, and it is therefore necessary to define the minimal safe procedure for preparing the hands.

The only logical reason for scrubbing the hands is based on the assumption that the organisms on the surface of the hand are different from those in the glands and are more dangerous. Clearly they consist of three groups: (1) those from the air, which are assumed to be harmless; (2) those picked up when touching surrounding objects; (3) those from the ducts. It is those in the second group that are potentially dangerous. Undoubtedly unwashed hands are a source of great danger if they are allowed to come into contact with virulent organisms through touching any form of septic material. If, however, one no more dreams of introducing the uncovered hand into any cavity of the body than of introducing fæces into the peritoneal cavity, and if one never does a

* Being an extract from a paper read before the Royal Academy of Medicine in Ireland (Obstetrical Section), to be published in full in the Journal of Obstetrics and Gynæcology of the British Empire.

septic dressing, nor even touches the surrounding area of a wound with ungloved hands, whence are the pathogenic organisms to be gathered? Apart from the fact that quite a considerable number of surgeons operate without gloves, it is almost impossible to trace a single case where an infection of a surgical wound can be traced to the hands of the operator. Colonel S. T. B. Williams (late I.M.S.) allows me to say that he performed major operations for years in India without using rubber gloves. Neither he nor his Indian orderlies washed their hands, but immersed them for one minute in a solution of carbolic (1-20). He never had any reason to consider a change in this method, which was so warmly advocated by Lister.

By experiment we found that the unwashed hand always grew air-borne organisms and the *Staphylococcus albus*. I never succeeded in finding a streptococcus. We also found that washing, however thorough, always increased the number of organisms on the hand. As a result of these experiments it is suggested that the following method of treating the hands, while it may not be the best, is simple, consistently efficient, and does not damage a delicate skin. Unwashed socially clean hands should be rubbed together for one half minute in a 1-1000 solution of biniodide of mercury, and then rubbed together in commercial spirit for one half minute and allowed to dry. A sterile swab may be used to rub the hands with the spirit, and the hands may be dried with a sterile towel if preferred. The routine advocated is as follows.

1. Every student and midwife should be trained to keep the hands socially clean. The only way this can be done is to insist that the habit be formed of cutting or filing the nails down at a definite time on a definite day of the week.

2. Abstention is all-important. Every doctor, student, and midwife should carry a pair of well-fitting unpunctured rubber gloves in a suitable pouch. When required the gloves can be put on, using powder if necessary. The gloves when on should be washed and rubbed together in antiseptic as above described. Any number of cases can be examined or dressed, the same routine being carried out between each case. At the end of the morning the gloves should be washed, treated with antiseptic, dried on an ordinary towel, powdered, and returned to the pouch. The outside of the glove becomes the inside on the next occasion, and is found to be sterile.

3. If there is any possibility of the gloves being punctured during the operation the hands should be treated as above suggested before the gloves are put on. After the hands have been treated, and the gloves have been put on and sterilised, the gown is put on. The gloves are pulled up over the end of the sleeves and re-rinsed in biniodide. Between operations the gown can be changed and the gloves re-sterilised. Punctures with a fine needle do not matter, but if any obvious puncture is made the glove should be changed. Before making vaginal examinations, removing placentæ, &c., it is quite unnecessary to treat socially clean hands before putting on the gloves.

This technique, it is contended, will cut down the expense of gloves to the hospital, will save a lot of trouble to the nursing staff, and inculcate logical ideas in the minds of future practitioners. It will be of still greater importance in the practice of midwifery in private. When one is called to a dirty house to clear out an abortion or to put on the forceps single-handed, it is impossible to carry out the theatre ideas of asepsis. It is often impossible to get frequent changes of water in which to wash. Very often the patient has to be moved in the middle of the operation or the anæsthetic has to be seen to. It is partly because a blind and pathetic faith in the inherent asepsis of a once boiled glove is so strongly entrenched in the mind of the present-day student that the results in midwifery are so lamentable.

The above technique is logically sound, is bacteriologically confirmed, and has been thoroughly tested by me in the obstetrical and gynæcological practice of the Rotunda Hospital. Let us avoid the danger of being lost in admiration of a ritual which appears attractive merely because of its inherent difficulties.

Part II.—(J. W. B.).

The technique used for the bacteriological control of the various methods of hand preparation was to wash with 10 c.cm. of sterile saline, using a sterile swab with which the hand was well scrubbed; 1 c.cm. of this saline was added to a tube of melted agar at 48° C. and a plate poured. After 48 hours' incubation the number of colonies was counted. The method of sterilising the glove on the hand was tested, firstly, on an ordinary non-sterile glove; secondly, on a glove contaminated with pus and fæces; and, thirdly, on a glove on which a culture of *B. coli* had dried. In all cases the glove was sterile when examined after treatment on the hand. Since the method was obviously efficient for the sterilisation of the exterior of the glove it remained to examine the condition of the hand within the glove, an important matter owing to the possibility of bacteria escaping from the hand through a puncture in the glove.

First, a number of socially clean hands were tested and from them bacteria varying from 80 to 6320 were removed by the washing process. Then similar hands, which had been enclosed in sterile gloves for periods of from one to two hours, were examined and the bacteria were found to number from 1380 to 25,000. As regards the preparation of the hands, it was found that thorough washing, as practised in operating theatres, increased the bacteria easily removable, in one case from 1300 to 35,000 and in another from 5080 to 18,400. Subsequent treatment with 1 : 1000 biniodide eliminated the majority of these. The commonly used method of inserting the washed hand into a glove containing 1 : 1000 biniodide was found to give very varying results, from 0 to 14,700 bacteria having been found on hands so treated. The substitution of sterile water for biniodide was even less successful, and "wet" methods were decided to be unreliable from the bacteriological point of view, in addition to being injurious to the skin. It was found that spirit alone, without previous washing, the hand being allowed to dry before a sterile glove was put on, gave very good results. In one case a hand so treated after two hours only yielded 20 bacteria, while the other hand, entirely untreated, gave 3310.

Dr. Theobald's technique was tested 19 times, the gloves remaining on the hands from one and a half to five hours. On three occasions the hands were sterile. Twelve times the bacteria were 100 or less. Only in two tests did they exceed 350. A really bad result was only obtained once, 3220 bacteria, and here it is believed that some gross error had been made either in the technique or in the testing. In the case of a dry hand very few bacteria could escape through a small puncture in the glove, and if infected material is avoided by the bare hand the chance of these being pathogenic is remote. The bacteriological tests have supported Dr. Theobald's contention that his method is a safe one for surgical and obstetrical practice.

Brighton, Hove, and Preston Dispensary.—The financial position of the institution had for years been causing considerable anxiety to the governors, and the year 1922 closed with a serious deficiency; great efforts were made and the year 1923 closed with a balance in hand of £62. At the annual meeting of the governors on Feb. 12th Alderman and Mrs. W. Jago were appointed life-governors in recognition of their valuable services in raising money for the institution. The governors accepted with regret the resignation of Colonel C. Somers Clarke, for many years hon. secretary. The annual report showed that 3879 out-patients were treated—820 at the parent establishment, 838 at the northern branch, and 2221 at the western branch—while the total number of patients visited at their homes was 1403, the number of visits paid being 9929.

BED-ISOLATION,

WITH SPECIAL REFERENCE TO MEASLES AND CHICKEN-POX.

BY E. H. R. HARRIES, M.D. LOND., D.P.H.,
MEDICAL SUPERINTENDENT, BIRMINGHAM CITY HOSPITAL, LITTLE BROMWICH; CLINICAL TEACHER OF INFECTIOUS DISEASES, UNIVERSITY OF BIRMINGHAM.

RECENT reports of the experiences of different observers [1 2 3] who have instituted the system of barrier-nursing, known as "bed-isolation," have rendered any fresh description upon my part of the technique of the method unnecessary. I have myself given brief accounts elsewhere [4 5] of the working and results of the system at Little Bromwich Hospital. In this paper I propose to give some instances of success and failure in the bed-isolation of cases of measles and chicken-pox.

The technique of bed-isolation, which I personally learned from Dr. C. Rundle, of Fazakerley, some 12 or 13 years ago, has—probably with some modification—been carried out by various workers. It is possible, of course, absolutely to standardise technique, but it is obviously not possible to standardise the all-important human element which necessarily has to carry out the technique laid down. Nevertheless, it may be assumed—and this is certainly true of my own hospital—that at every institution at which the method has been given a trial the best available nursing staff, under a good surgically trained sister, has been employed to work the ward. It goes without saying that if we have in bed-isolation a method which can entirely replace not only the orthodox isolation block of small separate wards but the cubicle block for all the purposes to which such blocks are put in infectious diseases hospitals, then we possess a method which, particularly in these days of high building costs, is one of enormous utility and economy.

The value of bed-isolation in every-day fever hospital practice must, I submit, be judged rather by its failures—where failures have occurred—than by any aggregate of successes. It is easily possible, as a glance at my registers would show, to state with perfect truth that a large number of cases had been nursed in bed-isolation without any instance of cross-infection having occurred. This may convey very little. It is well known to all of us that certain of the acute infective diseases may be perfectly safely nursed in the same ward as patients suffering from other infections, or from no infection at all, provided the principles of barrier-nursing are carried out. But there are other of the acute infections about which we are not so sure.

Measles and Chicken-pox as Tests.

Dr. Frederic Thomson considers that measles and particularly chicken-pox constitute a fair if critical test of the system. I agree with him, if only for the reason that, in this country at any rate, these are the two diseases which so frequently give rise to administrative difficulties not only in fever hospitals but in hospitals for sick children and other children's institutions. If these two diseases are admitted to be fair criteria, then the questions to be decided are the following:—

1. Can bed-isolation completely replace for the segregation of measles and chicken-pox, admitted in any stage and in any number, the ordinary isolation block of small separate wards or the cubicle block?
2. If it cannot wholly replace these other systems in the case of these two diseases, to what extent, if any, can it replace them?
3. If it cannot replace them wholly or in part, what are the probable reasons for failure?

The System in Being at Little Bromwich Hospital.

The bed-isolation system at Little Bromwich Hospital has now been working for three and a half years. During this time in round numbers 1200 cases have been admitted to the wards in which the system is employed. The first 800 cases or so were nursed in a ward in which a wall space of only 9 ft. per bed was allotted; for the succeeding 400 a better ward has been in use in which a wall space of 12 ft. per bed is allowed.

The original ward contained in each division—the divisions being separated by a central kitchen and lobby—eight beds and eight cots—i.e., a total of 32. The present ward contains six beds and six cots in each division, and also possesses two side-wards opening off each of the main divisions. (These side-wards usually receive members of the nursing staff who may be suffering from diphtheria or scarlet fever.) In the original and in the present ward one, and sometimes two, iron cradles have been frequently employed in addition, for the reception of infants up to a year old. These cradles, when in use, are invariably placed in the middle line of the ward, near the central fires, and never along the walls.

In both the wards employed beds have always occupied one side of each division and cots the other. This is a factor of some practical importance in estimating results, since it is obvious that the test of the system must be more severe in the case of the very young susceptible children occupying the cots than in the case of the older children and adults occupying the beds. This arrangement, although not necessarily eliminating the human immune barrier, certainly alters the probable distribution of these barriers in the ward.

Before proceeding to an examination of results it is, I think, necessary to state the reason for introducing "bed-isolation" at Little Bromwich Hospital, since the reason for the introduction of the system may have a very important bearing upon the extent and variety of the infective material admitted to the ward.

Incidence of Cross-infection.

The original ward at Little Bromwich arose not out of any desire to test the limits of the system, but out of the sheer necessity for providing at a time of epidemic diphtheria, scarlet fever, and measles additional accommodation for cases which for one reason or another it was impossible or undesirable to admit either to the ordinary scarlet fever or diphtheria wards or to the orthodox isolation blocks, which were full. Hence, every case admitted to the ward was accompanied by the pious hope that no cross-infection would occur.

In the course of nursing 1200 cases cross-infection has been initiated by measles on three occasions, by chicken-pox on three occasions, and by scarlet fever twice. Six of these eight breakdowns—viz., measles twice, chicken-pox three times, and scarlet fever once, occurred in the original ward (with a wall space of 9 ft. per bed). When measles "crossed" on two of the three occasions the child in the adjoining cot only was infected (once with a wall space of 9 ft. and once with 12 ft.); on the third occasion three children on the opposite side of the ward were infected. (This outbreak will be discussed later.) In the case of chicken-pox on two of the three occasions of breakdown an extensive ward infection followed; on the third occasion the child in the next cot only was infected.

The bald statement given above possesses little scientific value. In order that some opinion may be formed, it is necessary to know not only how many times measles, chicken-pox, and scarlet fever have been introduced into the ward, but in what stages they were introduced, and also to have an idea of the number of other patients "at risk" on specific occasions. With regard to scarlet fever, beyond stating that this disease has in various stages and with various accompanying conditions been nursed in bed-isolation on hundreds of occasions, and that in both instances cross-infection was due to proved personal contact (in breach of rules) of a child in an infective

condition with another, I do not propose further to consider that disease in this paper. It is well recognised that the infectivity of scarlet fever is low and that it can be barrier-nursed with very slight risk of spread.

Measles.

I have analysed the first thousand cases admitted to the ward and I find that in that total were comprised 63 cases of measles. It is generally agreed that the infectivity of measles has become very considerably lessened by the time that the exanthem is fully out; hence, it is important further to classify these 63 cases according to the state of disease on admission. The admissions were distributed as follows:—

1. Pre-exanthem stage—i.e., either incubating or Koplik's spots only present on admission	23
2. Exanthem appearing or fully out on admission ..	30
3. Exanthem faded on admission	10

Thus, of the 63 admissions about a third inhabited the ward during their most infective phase. In each of the three instances of cross-infection by measles the originating case belonged to the first or pre-exanthem group.

Chicken-pox.

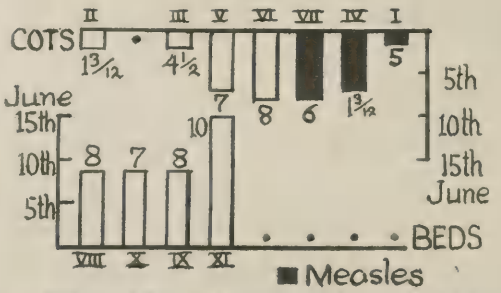
A similar analysis of the first thousand cases dealt with under conditions of bed-isolation shows that chicken-pox was admitted on 24 occasions. These 24 cases may be divided as follows:—

1. Incubating	4
2. Early eruption	10
3. Scabbing	10

The three breakdowns after the introduction of chicken-pox were each attributable to cases admitted during the incubation period.

I must confess, having regard to the failure of so experienced a physician as Dr. Foord Caiger always to prevent the spread of chicken-pox in glass cubicles,[6] that I introduced chicken-pox into my bed-isolation ward with great trepidation. After a few successes with cases introduced in the later stages of the eruption I ventured on a case in the incubation stage and failed. As I have already mentioned, three out of four cases introduced at a similar stage

FIG. 1.



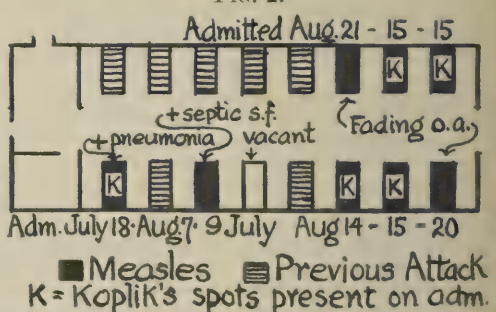
Measles: Order and date of admission and ages of first population of west division of ward. I., early measles; IV., measles with broncho-pneumonia; VII., early measles. No history of previous measles in other patients.

have led to subsequent cases. Whatever the cause—air-borne or human-borne infection—our experiences with early chicken-pox have been so unfortunate that I would not knowingly admit a case of this disease, at any rate in the incubation stage, to the bed-isolation ward, and I prefer not to admit it at any stage. Hence, the small total of admissions of this disease.

I must here refer to certain reconstructions of actual bed-isolation ward populations with particular reference to measles. All the diagrams which I have made are constructed from material furnished by the original ward—the wall space per bed being, as I have stated, 9 ft. From the point of view of air-borne infection this lessened wall space involves a more severe trial of the system than where a greater wall space obtains; and further, under these conditions the strain upon the nursing staff is greater, owing to the larger number of patients to be bed-isolated. Hence the first 800 cases dealt with at Little Bromwich constituted a rigorous test of the possibilities of aerial spread from bed to bed and of the quality of the nursing. In fact, these two conditions—limitation of wall space and strain on the nursing staff—may be considered as having borne too hardly upon the system. Are there any factors other than space and technique which may operate in favour of safe bed-isolation?

I have already indicated that in my opinion it is important to stress the stage of the disease under discussion at the time of its admission to the ward. Our failures with measles and chicken-pox occurred in connexion with cases admitted in the earliest stages. Again, I have myself stated that "as many as three cases of measles in the early pre-eruptive (Koplik's spots) stage have been safely treated at one time in a single division of the ward."[7] This is

FIG. 2.



Measles: Ward containing eight cases in various stages. Every other inhabitant of the ward had a previous history of measles. If the histories were correct there was no likelihood of cross-infection; in any case none occurred either in this (west) or in the east division of the ward.

perfectly true, but such a statement may not under all conditions have an equal epidemiological value.

For example, I have reconstructed (Fig. 1) the first population of the original ward which was opened on June 1st, 1920. On that day the first case—one of measles in the early stage (Koplik's spots present—rash just appearing) was admitted to Cot 16. The second case (Cot 9) came in the following day, and so on. The order and day of arrival of each case are indicated upon the diagram—the latter (day of arrival) by the length of the column. Only the cases admitted up to June 15th are shown. By that date Cot 10, and Beds 1, 2, 3, and 4 had not been filled and were not occupied until several days later.

From the point of view of risk of infection from measles, therefore, it will be seen that of the small community of 12 persons admitted in a period of 15 days, three came in with measles (two in the early exanthem stage) and one with exanthem fully developed. According to the histories obtained, none of the remaining nine patients had had measles. Histories of previous attacks of measles are, of course, not very reliable—the chances are that some of these nine patients had had measles. But even supposing they had not, what were the real risks of infection, air-borne or human borne? It will be seen by a study of the diagram that the greatest source of infection was probably introduced into Cot 14 on June 8th (early measles); risk of infection from Cot 15 (late measles) was negligible. No. 16—the first case admitted—would, in its phase of maximum infectivity, only be capable of infecting the inhabitants of Cots 11 and 9, who were admitted to the far end of the same side of the ward on the following day. Risk commenced at Cot 14. No. 5 arrived on the fifteenth day when all danger had passed. So that the risk of spread was really confined to seven inhabitants. No cross-infection occurred. Thus, although it is true to say that three cases of measles

[6] Reports M.A.B., 1907, 1908, quoted by Chapin, Sources and Modes of Infection, 1910.

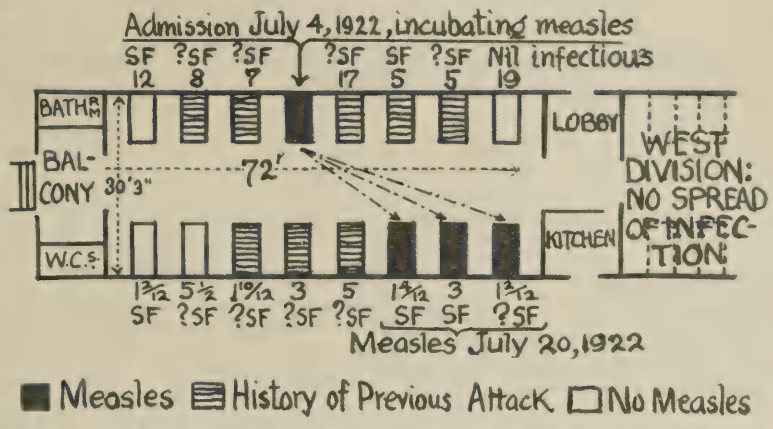
[7] THE LANCET, loc. cit.

two of them early) were nursed at one time in the ard, yet the real risk of spread at any one time is ery much smaller than this bare statement would eem to imply.

Fig. 2 shows what protection against measles crossing" may be afforded by reason of previous ttack. In this particular ward population there are ight cases of measles, five of them ıtroduced in the stage of Koplik's pots. The cases were admitted in he ordinary routine work of the ard—i.e., the remaining population as in no way selected or arranged. here is one vacant cot. Every one f the remaining seven patients ad a history of previous measles. herefore, if this history was correct, here was no likelihood of cross-ıfection. In any case none ccurred either in this (west) or the ast division of the ward. Protec-on as a result of previous attack ıay therefore be a powerful ally ı bed-isolation work.

Fig. 3 is a reconstruction of a ard population amongst which ɔread of measles occurred following ıe introduction of a case in the age of incubation. Three young ıildren on the opposite side of the ard developed measles on the same ate. Was infection air-borne or uman-borne?

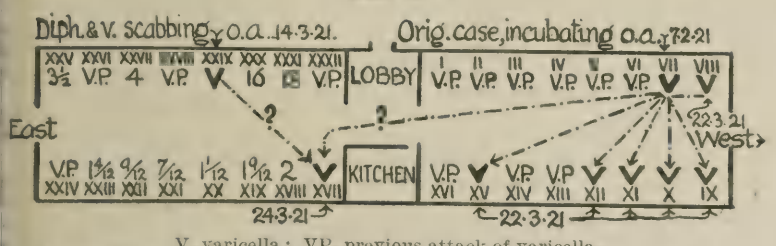
FIG. 3.



Measles: Diagram showing cross-infection originated by a case admitted incubating measles. Fifty per cent. of ward population protected by previous attack.

It will be noted that the line of spread was entirely ı one direction—that is, obliquely across the ward—nd that as much as 50 per cent. of the ward popula-on at the moment were protected by previous ttack. In favour of the air-borne theory it is of ıterest to note that at the east end of the ward is door opening on to a balcony and that this door ɔ that time of the year (July) would be almost ɔnstantly open; that the east end of the ward is ɛposed to what is practically open country, and that ı many occasions a breeze would be blowing through ıe ward from east to west. It is perhaps of some gnificance that the three cases infected were to the est of the infecting case. Is it not, however, much ore likely that these three children were infected

FIG. 4.



V, varicella; VP, previous attack of varicella.

Chicken-pox: Diagram showing distribution of cross-infection following a concealed case admitted in incubation period (see text). Every patient in the same division unprotected by a previous attack developed chicken-pox, except a three weeks old baby in a cradle. How was No. XVII. in the east division infected? By aerial spread, by a nurse, or from No. XXIX.—a very late case?

showed scars of chicken-pox. The tenth—a boy admitted with scarlet fever and lesions of scabies which had become impetiginous—was found on careful search to present three or four quite recent and typical scars of chicken-pox on the chest amongst his healing impetiginous lesions. I have no doubt that this boy, admitted in what must have been the commencement of his incubation period, was the source of infection for the others. Note that a three weeks old baby in a cradle escaped. Two days later a case of severe diphtheria with cardiac trouble in the opposite division of the ward developed chicken-pox. How was she infected? On examination of the other patients in this division it was found that No. 29 had been admitted with diphtheria and a few chicken-pox *scabs* ten days before No. 17 developed chicken-pox, No. 29 having herself developed chicken-pox some six weeks before admission to the ward. She was therefore a possible but unlikely source of infection.

The other possibilities are two—either that there was an air-borne infection from the far corner of one division of the ward through the lobby and round the corner to Cot 17 in the opposite division of the ward, or that infection was conveyed by a nurse from the infecting case not only to the six susceptible children in the west division of the ward—who simultaneously developed varicella—but to the very ill child needing constant attention in the corner of the east division. When I say that a night nurse on duty at relevant dates was found to have had an unreported bandaged finger impossible of proper sterilisation, I think there are some grounds for accepting the view that the diphtheria child in the other division at any rate was the victim of human-borne infection. The escape of the three weeks old baby is interesting from the point of view of immunity, since this child would need frequent attention, and was also—if the air-borne view be preferred—in the direct line of spread from one ward to the other.

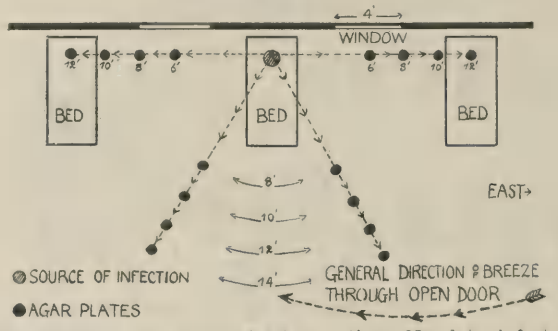
The other extensive outbreak of varicella originated with a child admitted as a "contact" and who duly

nultaneously as the result of a breach of technique ı the part of doctor or nurse examining or attending e introduced case and then proceeding without ficient sterilisation of hands to attend to these three ung children? My own belief is, that this is an stance of human-borne infection. It is understood, course, that the incubating child did not leave its d and stroll across to its neighbours.

Turning now to chicken-pox, I have reconstructed ıe of the three failures which is of some interest. g. 4 illustrates an outbreak following the admission what I have called a "concealed" case of chicken-ɔx and incidentally emphasises the ease with which icken-pox may be missed, and the difficulty of

developed the disease. The child in the next bed developed chicken-pox 17 days later. Eighteen days later a child in the opposite division of the ward developed chicken-pox, and from this case arose four further cases in the same division after 15, 16, 16, and 19 days respectively. In this instance it is impossible to exclude the possibility of air-borne infection in the first "cross"—i.e., to the child in the next cot, but it is also impossible, I submit, to exclude the view that infection was human-borne from the one division of the ward to the other. Air-borne infection may have accounted for the four cases of the third generation which arose in this division, the spread being in the direction of the breeze through the open door and to both cot and bed sides. In any case, the experience was sufficiently unfortunate, and resulted in the ward being put out of action for a considerable period.

FIG. 5.



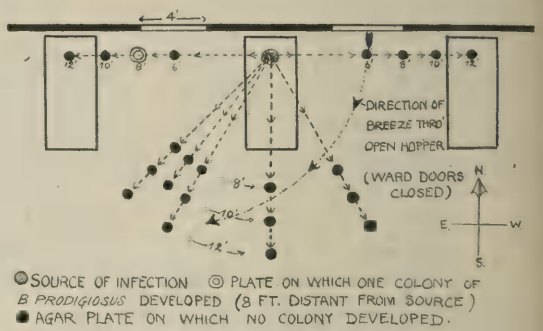
Experiment 1.—Result completely negative. No plates infected with *B. prodigiosus*.

Experiments with B. prodigiosus.

In conjunction with my colleague, Dr. Hubert Henry, City Bacteriologist for Birmingham, an endeavour was made to ascertain how far an organism could be projected by coughing. Advantage was taken of the fact of the old bed-isolation ward being empty after cleaning and a section of the east division was arranged as regards spacing of beds exactly as when the ward was in use for bed-isolation. The organism proposed to be employed was that well-tried favourite of similar experiments—*B. prodigiosus*.

On the day preceding the first experiment a number of agar plates were exposed in various parts of the floor of the ward and left for 25–30 minutes. These on incubation showed no evidence of the presence of *B. prodigiosus* in the ward. Accordingly, on the following day a series of plates was arranged as in Fig. 5. I then heavily infected my own throat with a broth culture of *B. prodigiosus* and arranged myself on the central one of the three beds exactly in the position of a patient. Dr. Henry then uncovered the plates, and I coughed vigorously and repeatedly—partially raising myself on the bed to do so—first to right and left of the bed and then obliquely forward over the bed to right and left in the line of the plates. The plates were left undisturbed for 25 minutes and were then covered and collected by Dr. Henry, who, after incubating them in his laboratory, reported that not a single colony of *B. prodigiosus* had developed on any of the plates. It will be noted in the diagram that a breeze (it was a July day) was blowing through the open door. The general direction of this breeze is denoted by the arrow. On the whole it tended to blow *against* the direction of my coughs.

FIG. 6.



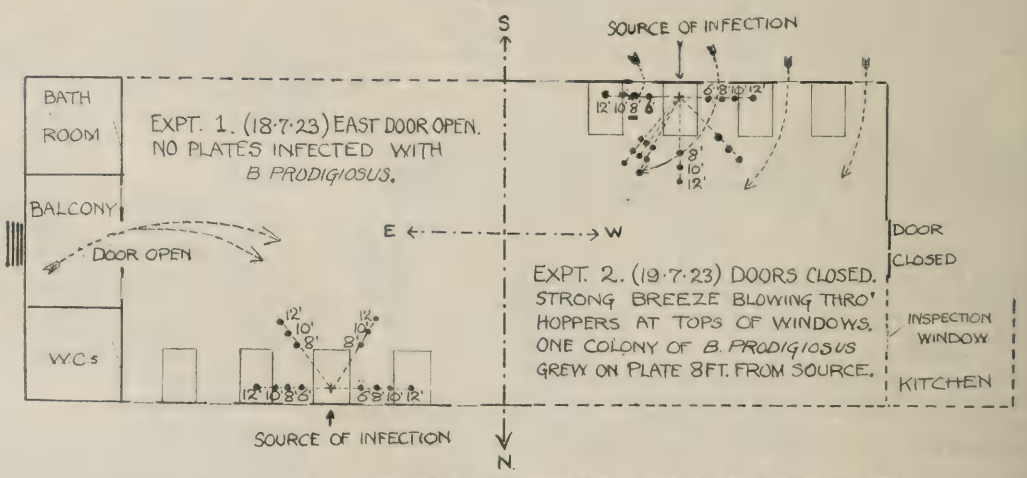
Experiment 2.—With *B. prodigiosus*.

On the following day the opposite side of the same division of the ward was used, three different beds being set up. In this experiment the ward doors were closed, but a breeze was blowing through open hopper windows behind and above the beds. The general direction of the breeze is again shown by an arrow. An additional number of plates was employed in this experiment (as shown in the diagram). I again infected my throat and again endeavoured to cough vigorously in the lines of the plates. The plates were again allowed to remain 25 minutes, and then dealt with by Dr. Henry as before. Dr. Henry reported that a single colony of *B. prodigiosus* had developed on the plate which had been placed 8 feet due east of my head. It will be noted that the direction of the breeze in this instance was towards the east end of the ward.

(Fig. 7 is a combination of Figs. 5 and 6 in order better to show the relative positions in the ward at which the experiments were made.)

These two experiments, of course, are no more than suggestive, and I do not for a moment attempt to draw any deduction from them. All they do show is that an adult artificially infected with a known organism

FIG. 7.



Combined diagram of experiments on successive days in empty east division of ward.

nd simulating the act of coughing in certain directions vas—with a breeze assisting to an unknown extent—ble to infect an agar plate 8 feet away—and no urther—in a direct line with his head. Many more xperiments under more varied conditions are desirble. It does not follow that because *B. prodigiosus* ould only be propelled 8 feet that the virus of measles r of varicella cannot be spread further by a patient ctually suffering from one disease or the other.

In this connexion attention may be drawn to a very aluable contribution by Wynter Blyth to the Section f Public Health at the British Medical Association nnual Meeting, 1923.[8] This author criticises much f the experimental work which has been done in onnexion with the bacteriology of sewer air and mphasises the conditions which obtain where rganisms are carried in bubbles. He says:

> The thinnest bubble . . . could carry an organism with diameter some 17,000 times greater than the thickness of he film. When a bubble breaks there is no 'explosion' ut the film, as it were, 'flaps back' at the rate of 72 miles n hour, and it is this force which ejects the comparatively normous organism. Absorption of liquid by the organism s one of the factors in determining its convection by light urrents of air, and such absorption is minimised if the rganism has been in contact with grease. It was found by xperiments with *B. prodigiosus* that the maximum time aken to fall through 100 cm. when discharged from a ubble of soap was one minute, and when discharged from bubble of gelatin 45 seconds.
>
> ". . . The volume of the globule of water and organisms to hat of the naked organism is . . . about 1000 to 1. Neverheless, these particles are small enough to be carried conderable distances by low velocity currents of air as much s 6 feet in a draught of only 30 feet per minute."

The possibility of bubble infection under conditions f bed isolation deserves further investigation. With egard to the extreme infectivity of chicken-pox at its arliest stages, the work of Girard [9] on complement leviation in chicken-pox is interesting. Girard found hat the reaction appears in the early days of the lisease—from the first to the sixth; by that time it s only feebly positive. Girard used as an antigen a saline extract of varicella scabs. It does not follow, f course, that the antigen is necessarily the virus.

Summary and Conclusions.

May I now, if only to serve as points for discussion, ummarise the conclusions I have arrived at:—

1. Bed-isolation cannot replace small separate vards for the nursing of measles and chicken-pox n their earliest phases. These diseases in their later nd less infective phases may be safely nursed under onditions of bed-isolation.

2. For short distances it is impossible to exclude the heory of aerial spread—possibly by bubbles in the ase of measles. For distances of many feet human-orne infection is much more probable. Cases of neasles and of chicken-pox in their later phases can e successfully nursed with a wall space of 9 ft. er bed. A wall space of 12 ft. has not entirely revented cross-infection by measles admitted in the arly stage. Nevertheless, a wall space of not less han 12 ft. per bed should be available. This ensures a maller number of patients in the ward, and hence ess probability of the staff becoming overworked and lurring the technique.

3. Protection by previous attack plays a part which lways is important but which varies with different liseases, and with the age distribution of the ward opulation. In the case of measles as much as 50 per cent. of the ward population at any time may e protected by previous attack.

4. In spite of its limitations in the direction of arly measles and chicken-pox, bed isolation is a valuable method for the treatment of conditions of elatively low infectivity and of non-infective conditions in the same ward. It is a method which lepends for its success almost entirely upon the skill nd integrity of the nursing staff.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PATHOLOGY.

A MEETING of this section was held on Feb. 19th, Dr. J. A. MURRAY being in the chair.

"Aleukia."

Dr. S. C. DYKE recorded observations on six cases of this condition, all characterised by a leucopenia of varying degree, with a relative and actual diminution of the polymorphs; in all the platelets were greatly increased in numbers. Clinically all the cases showed a hæmorrhagic tendency, and some had been labelled with the diagnosis of purpura hæmorrhagica. Sections of the spleen and bone marrow were shown from three of the cases; these showed in one instance a streptococcal, in the second a tuberculous infection, and in the last the presence of coliform bacilli. Dr. Dyke discussed the question as to whether the infection was to be regarded as the cause of the anæmia and hæmorrhagic manifestations, or whether the infection had merely gained a foothold as a result of the aplastic state of the hæmatopoietic system. The conclusion was that the myelophthisic state was primary and the infection secondary.

Experimental Biliary Cirrhosis Due to Manganese.

Dr. G. MARSHALL FINDLAY said that although cases of chronic manganese poisoning had been described among industrial workers on the Continent, in America, and also, more recently, in this country, comparatively little was yet known in regard to the pathological changes produced by manganese. This lack of knowledge might be due to the fact that the post-mortem examination of only one case of chronic manganese poisoning in man has so far been recorded (Casamajor, 1916), while attempts to produce manganese poisoning in animals had not been very satisfactory. Experiments were therefore carried out on rabbits, guinea-pigs, and rats. When manganous chloride was injected subcutaneously into rabbits in doses of from 20–80 mg., the animal usually died in from one to two days. Microscopically, there was found very marked fatty degeneration of the liver parenchyma, while in the kidneys there were hæmorrhages into the glomerular capsules and degeneration in the tubular epithelium. When smaller doses of from 3–5 mg. were injected subcutaneously for from six to eight weeks, the rabbits usually showed a decline in body-weight and in some cases a rigidity of the hind limbs and neck. On post-mortem examination there was frequently an icteric tint in the subcutaneous tissues, but no evidence of ascites. The liver was usually enlarged, the surface being either smooth or slightly roughened and the colour yellow or yellowish red. Microscopically in the liver there was found an increase in fibrous tissue accompanied by a small round-cell infiltration and the formation of fresh bile capillaries. These changes were at first restricted to the portal spaces, later they extended round the periphery of the lobules, giving rise to a form of cirrhosis definitely monolobular in type. Subcutaneous injections of manganous chloride in guinea-pigs were followed by results entirely similar to those described in rabbits, the liver showing the various stages of biliary cirrhosis. Rats, when repeatedly injected with manganous chloride, also developed a cirrhotic condition in the liver, accompanied by jaundice but unassociated with ascites. In some cases they exhibited a rigidity of the legs and neck. The fibrosis in the liver was at first confined to the portal spaces and to the periphery of the lobules, but later it extended between the parenchymal cells, dividing them up into little islands. Many of the liver cells were hypertrophic and all showed fatty changes. A number of rats also were fed on manganous chloride which was added to their ordinary diet. In from six to ten weeks they likewise developed

a cirrhosis of the liver associated with jaundice and in some cases with rigidity of the limbs. The microscopical appearances in the liver were similar to those produced by the subcutaneous administration of manganese. It was of some interest to note that many medicinal waters contained small though quite appreciable quantities of manganese salts in solution. The selective action of manganese on the liver would appear to be due to the fact that it was largely excreted from the body by the bile. It was only when large doses were administered parenterally that small amounts might appear in the urine. The similarity of chronic manganese poisoning to the syndrome of progessive hepatico-lenticular degeneration described by Kinnier Wilson (1912) was extremely striking. The nervous lesions occurring in the animals used in these experiments were at present the subject of investigation.

A communication on Growth-promoting Substances and Embryonic and Tumour Extracts, by Mr. A. H. DREW, was also read.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society was held at the rooms of the Medical Society of London on Feb. 29th, Colonel L. W. HARRISON, the President, being in the chair.

A Suggested Investigation.

The PRESIDENT intimated that the Council had given consideration to a statement [1] made at a recent discussion to the effect that the modern intensive treatment of syphilis was responsible for an increase in neuro-recurrences in syphilitics. There were divergent views on the matter, not only here, but on the Continent, and it was very desirable to settle it. Therefore the Council desired that members should investigate the point, each in his own clinic. During the war about 100,000 soldiers had had a necessarily short course of salvarsan and mercury treatment, and as the war started nine years ago, the time was approaching when the aftermath of syphilis of the parenchyma of the central nervous system among those cases could be expected. On the basis of a 4 per cent. incidence of general paralysis of the insane and 2 per cent. of tabes, then some 6000 of those war cases could be expected to present themselves with syphilis of the parenchyma of the central nervous system. He believed there was nothing like that number in the whole country, and in the treatment centres none, or very few, had been seen. He hoped this combined inquiry would settle this important question once and for all.

Dr. F. N. KAY MENZIES supported the President and advocated the issuing of a questionnaire to all in charge of venereal clinics.

Dr. WILFRID FOX said a similar statement was made after each advance in the treatment of syphilis had been introduced. Some thought neuro-recurrence would ensue if anything more than Hutchinson's pills were given.

A discussion was then held on

The Instruction of the Medical Profession and of the Lay Public with Respect to the Facilities Provided for the Diagnosis and Treatment of Venereal Disease.

Dr. MENZIES, in opening, pointed out that by Article IV. of the Public Health V.D. Regulations, 1916, county councils and county borough councils must arrange lectures and addresses of an instructional character, as well as for the publication of any information which was likely to be of value, either to the medical profession or to the lay public with regard to venereal diseases. Those in the London County Council took the view that it was best that some things should be done by the public authority itself, while others could well be delegated to voluntary bodies, which should be paid for the duties they carried out in furtherance of the scheme. The whole profession in London was circularised, giving particulars of the schemes for treatment and the facilities which had been set up, where material could be reliably examined, and a report furnished; also how the members of the profession could be merged into and be helpful to the whole crusade. Certified practising midwives were also supplied with the necessary information on the subject; these could be very useful in bringing cases suffering from syphilis to the clinics. Other circulars were sent to maternity and child welfare centres, Poor-law authorities, and prison authorities, the last-named because of the number of prisoners who might still be in an infective condition when their sentences had expired. Magistrates, police, and bodies of social workers were also circularised. Next, a scheme was started for informing the public where treatment could be obtained, and Dr. Menzies showed specimens of posters which had been exhibited in public lavatories and other suitable places. He described the evolution which the Council passed through due to changing views as to what were the most efficacious means of reaching the public. In 1919 special series of addresses to employees of controlled firms were organised, and film representations setting out the dangers of the disease were frequently shown. Special committees were also started in the various metropolitan boroughs to assist the propaganda work. The L.C.C. had now dropped the press portion of the campaign. In London the pathological examinations made for practitioners in connexion with the disease numbered 3000 in 1917; in 1923 it had risen to 24,000. The teaching facilities to the profession had given, so far, a rather disappointing result. The all-day clinic had been found to be of enormous advantage. Four hundred London practitioners had now taken up the offer of salvarsan and substitute drugs free of charge, having produced the necessary certificate of competence to use them. Hints as to better or more likely lines of attack had been invited, but to this the critics had made a very poor response.

Mr. FRANK KIDD agreed that the propaganda which had been carried out by the L.C.C. was admirable, but as there had been some very unwise propaganda indulged in, he wished to utter a warning. It was, he thought, a mistake to use fear of disease as a weapon for inducing people to come for treatment, though probably it had been a factor in getting the V.D. clinics started, and without the clinics it would not have been possible to train doctors to use the new means of treatment. In the long run schemes of propaganda based upon fear were bound to fail; and a new malady seemed now to have arisen, which he might call propaganda disease. There were now an increasing number of patients with syphilophobia and gonorrhœophobia, who consulted the doctor with a fixed terror of venereal disease. They believed they would never be cured, that they would not be able to marry, and would die insane. They had read a number of alarmist statements in the papers, and believed them to be true. At a venereal section, of 630 attendances, 34 were women who applied because they suspected their husbands after reading propaganda advertisements, but none of the husbands were found to be diseased. Three others who were free of disease came because what they had read in their Sunday paper made them uneasy. Many—mostly men—applied for expert examination before marrying. In many with diseased minds on the subject it was found to be difficult, if not impossible, to cure them. Some of the patients had been in the hands of unwise and inefficiently trained men, and in them there was no evidence that there had been disease for a long time. Mr. Kidd quoted a number of cases illustrating these points. He urged that in this campaign an appeal should be made to the highest instincts, the building up of character and of good clean social habits. He would rather see 10 per cent. of the population suffering from venereal disease than 50 per cent. suffering from, weighed down by, the fear of it, and he held a similar view on the subject of the cancer campaign.

[1] See THE LANCET, Jan. 19th, 1924, p. 131.

Mr. E. B. TURNER dealt with the question from the standpoint of the general practitioner. He said he agreed largely with what Mr. Kidd said concerning propaganda on the wrong lines, but, as one who was responsible for a great deal of propaganda on this subject, he was convinced that propaganda on right lines did an enormous amount of good. There might be cases of syphilophobia, but the campaign had brought to many the realisation that they had the disease and how important it was that they should be promptly treated for it. The free clinic was a wonderful way of treating the disease and diminishing its incidence. But it became a different matter in rural and other sparsely populated districts. There clinics were few and far between, and the servant or farm-hand could not get leave from work to attend a distant clinic. When clinics were set up in the suburbs of large towns patients preferred to go into the town because they felt more secure from suspicion among their fellows. The only remedy seemed to be the education in these matters of the medical profession as a whole, and it was this need which made him urge a general recognition of the subject by the General Medical Council in the medical student's curriculum. Even though some medical men preferred not to treat venereal disease every practitioner should be able to take a smear and make a diagnosis and, if positive, direct the patient to the place where he could be efficiently treated. The aim should be to get cases at the beginning, and to that end the whole profession should be organised.

Prof. WINIFRED CULLIS said that, as a physiologist, she had always sought to emphasise the supreme importance of maintaining a high standard of health. She agreed with Mr. Kidd in deprecating the use of fear as a motive. Remedial measures were good, but how much better to be able to abolish the need for those measures. Unless the general populace could be educated as to the need to go to the clinics, the latter would do no good. With regard to syphilophobia, a certain proportion of people suffered from mental instability, but that was not a good reason for abolishing propaganda, which admittedly brought many people to the treatment centres. If physiology were more generally taught she thought there would be a much more sane and helpful attitude in regard to sex matters; there was still appalling prejudice on the subject, even among those who considered themselves educated, including the clergy. Help was required for the necessary teaching among the younger people. Positive knowledge was one of the best preventives.

Mrs. NEVILLE ROLFE, representing the National Council for Combating Venereal Diseases, said this body wished to push this campaign further than the public purse would support at present. During the last two years the National Council had been able to carry through a large amount of propaganda work against these diseases. She did not think the success of the campaign should be judged by its effect upon people who were abnormal, though she agreed with Mr. Kidd and others that the ground-work of the efforts should not be the instilling of the fear of the consequences of disease. Knowledge of the consequences, however, should not be withheld, nor should the bad results of neglecting to continue treatment. After a propaganda film was shown in a district the immediate attendances at the local clinic were often doubled. The Council had first to bring venereal disease up to the level of other public health subjects in the national consciousness, and she believed the right line now was to take all health subjects together and no longer concentrate on these particular diseases. Efforts should be made to reduce the agencies which promoted promiscuity. In four years the various notices had resulted in 87,600 letters being addressed to the National Council, a large number of the writers of which believed themselves to be infected and asked where they could obtain treatment. Mrs. Rolfe proceeded to speak in detail of the activities of the Council and the steps taken in the interests of men in the Mercantile Marine.

Colonel E. T. BURKE thought that such cases as Mr. Kidd spoke of were exceptional. Certainly the teaching of the general practitioner in these matters was essential, and it should be made a compulsory subject in the medical student's curriculum. Students should be required to have three or six months in the work of a V.D. clinic, so that a regiment of men would be built up who would be familiar with the matter on entering general practice. Colonel Burke spoke of the harmful effect of the statement of some doctors to their patients that three or four injections of "606" would put them right.

The PRESIDENT said he was sure Mr. Kidd would agree that propaganda was good so long as it was wise. He had long felt that all that was required was a plain statement of the case, without exaggeration, with emphasis on the value of thorough treatment, and its effect in preventing horrible late sequelæ. He thought the posters in the public lavatories were in the wrong place. In 1919 an offer was made by the Insurance Committee of London to give post-graduate instruction at Rochester Row, and in two years 400 practitioners attended that course. At St. Thomas's Hospital it was made compulsory for all dressers to attend the instruction on venereal disease in the centre. If that were followed at all hospitals it would do much to anticipate the benefit which would later accrue from the steps taken by the General Medical Council.

Dr. MENZIES briefly replied.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A MEETING of the Fever Hospitals Medical Service Group of this Society was held on Feb. 22nd, Dr. E. W. GOODALL, the President, being in the chair.

Dr. E. H. R. HARRIES opened a discussion on

Bed-Isolation, with Special Reference to Measles and Chicken-pox.

His paper appears in the original columns of the present issue of THE LANCET.

The PRESIDENT congratulated Dr. Harries on his observations, but thought that little, if any, knowledge on the subject had been added to what was brought forward at the discussion held at a meeting of the Group in May last. In addition to the factors mentioned as being favourable to the spread of infection, such as the period of the disease, he would add the period of the epidemic. There was some evidence to show that certain diseases were more infectious during the waxing than during the waning of an epidemic. From his experience at the Eastern and North-Western Hospitals he had come to the conclusion that neither measles nor chicken-pox in the acute stage could be nursed, with safety to other patients, in a "bed-isolation" ward. In his experience cross-infection was more frequent in such a ward than in a ward or block consisting of completely separate rooms or chambers. That went to show that the conveyance of infection by air could not be ruled out. "Bed-isolation" wards should not contain more than 16 patients at the outside. The smaller the number of beds the better the result. It was desirable to provide the nursing staff employed in the ward with a written set of rules, but those rules should be simple and comprehensive. Local sanitary authorities must not be led into thinking that all kinds of acute infectious diseases could be treated together in the same ward under "bed-isolation" regulations, because even if it were found that the infection was never air-borne, it was quite certain that to prevent it being carried by any member of the staff that staff must be highly trained in these methods, and it was unlikely that the staff employed in small isolation hospitals would possess the requisite experience and technical knowledge. He thought it would be very difficult to defend an action-at-law brought in the case of a patient who had contracted a serious disease, such as measles, from another such case intentionally admitted into a "bed-isolation" ward.

Dr. FREDERIC THOMSON was glad that Dr. Harries assumed that at hospitals where "bed isolation" had been carried out the best available staff were employed for the work; evidence from the various hospitals concerned did not suggest much difference in efficiency of the staff, and any such implication would be invidious. Taking into consideration the size of these hospitals the choice of nurse must be ample, and it was more than probable that the nursing had been very good indeed. On the other hand, he could quite conceive that the requisite class of nurse might not be available in many small hospitals. He thought few could deny a measure of success to bed isolation as a mode of obviating the spread of infection by contact. Given a reliable staff, it was safe to treat mild or severe scarlet fever under such conditions, or, indeed, any disease of low infectivity, but accidents would happen just as in other methods of isolation. Of the few instances of the transmission of scarlet-fever infection, nearly all had been traced to some fault in the technique, such as the unobserved injured finger of a nurse, but the same danger would apply equally to blocks composed of single rooms. Much the same success had been obtained with diseases of higher infecting power in patients admitted at later and less infectious stages of the disease; but those who had admitted these diseases at the earliest stage had not been successful in avoiding the conveyance of infection to others; indeed, in chicken-pox admitted before the outcrop of the eruption the failure had been pronounced. It was interesting to discuss why failure arose in some diseases and not in others, but the broad fact remained that there had been failure under the best conditions of general management. As Dr. Harries had pointed out, it was easy enough to say with truth that one had treated a large number of infectious and other diseases in such a ward without cross infection, but in 1914 he had felt almost certain he could safely treat the diseases ordinarily sent into a "bed-isolation" ward were he to choose the day of the disease on which to send them there. Undoubtedly misconception had arisen because we did not fully realise that some diseases were much more infectious in certain phases; of this fact no better illustration could be given than Dr. C. Rundle's statement in 1912 that he had treated 41 cases of chicken-pox in his "bed-isolation" ward without cross infection, whereas the disease had been introduced accidentally into ordinary wards on 21 occasions, with cross infection in all but one instance. The explanation was now obvious, but was not realised by anyone then. He very much doubted if the cubicle block was any better than the "bed-isolation" ward, but the ordinary isolation block with single-bedded rooms, the doors of which opened on to the outer air and had no internal means of communication, was in his experience much more successful in the isolation of early measles and chicken-pox, mishaps being so rare as to point to some carelessness on the part of an attendant. On the other hand, those who had introduced measles and chicken-pox in the pre-eruptive stage to a "bed-isolation" ward had all failed, particularly badly with chicken-pox, since in the latter disease cross infection had arisen nearly every time. Of the seven exposures of chicken-pox at this stage in his ward, five were productive of the disease in others, and the two which failed to infect only endangered children who had already been exposed to a similar risk about a fortnight before. The experience of Dr. Goodall and Dr. Harries with chicken-pox at this stage appeared to have been similar to his, and as far as he was aware there were no other published experiences on this point. He thought there was little doubt that "bed isolation" could to some extent replace the single-bedded room, given suitable nurses. With regard to the reasons for failure of "bed isolation" wholly to replace the single-roomed block, he thought that in the earliest stages of certain infectious diseases infection could be conveyed through the air indoors by droplets, or some such means, for distances of 14 feet at least. It might be argued that attendants were less likely to be careless if working in a block of single-bedded rooms, because of the impression conveyed to their minds by the need for this complete isolation; or that in "bed isolation" the supervision of the ward was easier. In either case the supervision at night would not be complete and if the staff were good he did not think these arguments materially affected the case. He was not prepared to agree with Dr. Harries concerning the likelihood of infection of measles being human-borne rather than air-borne; and he did not think it would do to seek refuge in the reflection that it may be more difficult to wash from the hands certain infections, for if that was so the result in his single-roomed block could hardly have been so much better than in the "bed-isolation" ward.

Dr. D. MACINTYRE stated that, except in the case of chicken-pox, his experience of bed isolation was very similar to that of Dr. Harries. There appeared to be general agreement among those who had used the method that, excepting early measles and chicken-pox, most of the common infectious diseases could be safely nursed in a bed-isolation ward. This, he thought, marked a definite advance in our knowledge of the control of infection. With regard to chicken-pox, he had so far had no cross infection from this disease in the bed-isolation ward at Plaistow Hospital. Forty-two cases of chicken-pox had been safely treated in the ward during the past four and a half years. Some of these had been admitted in the first and second day of the eruption, but none had been in the ward during the incubation period. With measles his results had been different; cross infection had occurred during an epidemic in the spring of 1922, and again quite recently. Both failures had occurred when an epidemic had been at its height in the district and when the number of cases admitted to the ward had rapidly increased. During such epidemic periods patients admitted as scarlet fever and diphtheria were frequently found to be either suffering from or incubating measles, and it was often a difficult problem to isolate all these cases. He had made free use of the bed-isolation ward for this purpose, and his experience had led him to the conclusion that while measles in the eruptive stage could be controlled the number of such cases in the ward at the same time must be limited to one or two. The experiments carried out by Dr. Harries were very interesting, and he thought valuable knowledge might be gained by work along such lines. He entirely agreed with Dr. Harries regarding the value of a bed-isolation ward, especially in hospitals where small separate ward accommodation was limited.

Dr. HARRIES, replying, emphasised the importance of the time factor in connexion with the two experiments with *B. prodigiosus* detailed, and drew attention to the conception of "Velocity of Infection" due to Surgeon-Commander S. F. Dudley (Reports to Medical Research Council, No. 75). He believed that Dudley's theory applied to problems of bed isolation would prove of great value, and instanced his own experiences when acting as receiving officer at the base isolation hospital in Mesopotamia during the war. The method of collecting the infectious sick was for a launch twice a day to call at those depôts on the Tigris flying the yellow flag, and to collect in the same launch cases of most varied types of acute infections. The patients were placed on stretchers, and covered with blankets, and arranged on the floor of the launch. On arrival at Quarantine Island, the stretchers were removed from the launch, carried to the receiving room of the hospital, and again laid side by side on the floor. He had noted as many as ten different acute infections brought in at one and the same time: some water-borne, e.g., cholera and typhoid; others insect-borne, e.g., plague and relapsing fever; others, again, being such infections as small-pox, chicken-pox, and measles. In spite of the proximity of these patients in launch and receiving-room, he could recall no instance of cross infection over a period of many months. He ascribed this freedom of cross infection as in part due to (1) the types of disease, (2) the age-distribution of the patients dealt with, (3) protection by reason of previous attack, (4) the brief period during which proximity obtained, and (5) to the fact that the sick

Asiatic almost invariably covers his head with a blanket or garment. He agreed with the President that it was desirable to make the regulations for the working of bed-isolation wards as simple and concise as possible.

PARTICK AND DISTRICT MEDICAL SOCIETY, GLASGOW.

A MEETING of this Society was held on Feb. 21st, Dr. JOHN GRACIE being in the chair.

Dr. J. FERGUSON SMITH read a communication on

Furunculosis.

He said that his remarks were to be limited to the consideration of the state of having boils, as opposed to the treatment of the individual boil. There were two main factors in the production of a boil. One was the presence of pyococci, and the other was the presence of patulous hair follicles or ducts of glands by means of which the pyococci were enabled to reach the corium. Recent work had thrown doubt on the theory that the infecting organisms were those strains commonly found in the skin, and that these, by reason of some exaltation in their virulence, or depression of the resisting power of the host, became pathogenic. Recent work suggested that boils were produced by infection from a previous sufferer, and were due to pyococci quite distinct from those normally found in the skin. Later boils were thus lineal descendants of the primary boil or other septic lesion.

In the treatment of the condition the first essential was to remove any obvious predisposing causes such as scabies, pediculosis, and the friction of soiled clothing. The next was local antisepsis; a wet dressing should never be applied to any septic condition of the skin without the application of a strong antiseptic to the parts each time the dressing was changed. For this purpose Dr. Smith used perchloride of mercury, 1 in 1000 to 1 in 5000, depending upon the amount of inflammation and the texture of the skin; or acriflavine, 1 in 4000 in normal saline. Carbolic was irritating and relatively feeble. As the hands of the doctor and the patient carried the pyococci, attention should be paid to these. If these simple precautions were observed it was rarely necessary to have recourse to vaccines, the success of which was problematical. A vaccine should be autogenous, and given at four- to five-day intervals; an initial dose of 200 million should be gradually increased to one of 2000 million. Dr. Smith had had no good results from colloidal manganese; stannoxyl, he thought, had occasionally a good effect. He had not found that his patients were noticeably "run down" as a class, and while he treated the general health he did not think that such treatment helped greatly in the prevention of the furunculosis, except in cases of such gross disorder as diabetes. In conclusion, he mentioned what he considered to be the sheet-anchor of treatment—the use of X rays. These acted by producing a temporary partial atrophy of the skin glands and follicles, and thus deprived the cocci of their favourite nidus. The method was particularly applicable to localised furunculosis, as on the back of the neck and in the axilla.

SUSSEX THROAT AND EAR HOSPITAL.—The forty-fifth annual meeting of this hospital at Brighton was held on Feb. 6th. It was announced that in March leases of property adjoining the hospital, and belonging to the hospital, terminate, and the necessary legal formalities have been completed for the hospital to take possession. The extension comprises a waiting-hall, two consulting-rooms, a dressing-room, and an isolation ward, and it was announced that the governors had practically the required sum in hand. In-patients during 1923 numbered 663, an increase of 91 over the previous year, and out-patients had fallen from 1320 to 1002, due to the fact that on three occasions during the 12 months the hospital was closed to out-patients owing to infectious diseases.

Reviews and Notices of Books.

ORGANIC ARSENICAL COMPOUNDS.

By GEORGE W. RAIZISS, Ph.D., Professor of Chemotherapy, Graduate School of Medicine, University of Pennsylvania; and JOSEPH L. GAVRON, B.S., Associate in Research Chemistry, Dermatological Research Laboratories, Philadelphia. New York: The Chemical Catalog Company, Inc. 1923. Pp. 570. 35*s*.

THIS book of 570 pages is in the nature of a dictionary, with 1594 numbered references to a bibliography at the end of the volume. The "dictionary," in the present instance, discusses in more or less detail the single subject of organic arsenic. While there are to be found hundreds of original contributions to the chemistry and pharmacology of these bodies, distributed in dozens of scientific journals, the actual books dealing with the matter can be numbered on the fingers—this is certainly true so far as books printed in English are concerned. For this reason the authors deserve thanks for their painstaking effort in bringing the information together in up-to-date fashion. The book is issued under the auspices of the American Chemical Society "by arrangement with the Interallied Conference of Pure and Applied Chemistry, which met in London and Brussels in July, 1919," and thence the launching of this, and numerous scientific and technical monographs, passed by a sifting process to the hands of the Chemical Catalog Co. of New York City.

In the general introduction reference is made to Beilstein, Richter, and Ostwald specifically and the English and French dictionaries (non-specified) as available for study, but we should have liked to see an earlier acknowledgment to "Organic Compounds of Arsenic and Antimony," by Prof. G. T. Morgan, D.Sc., F.R.S. (Longmans, 1918)—the last mentioned is, of course, the English classic on this branch of chemistry—instead of occasional acknowledgment among the 1594 references at the end of the book. We view this failure to refer to an English chemist's classical treatise as unlucky, without any suggestion that it was intentional; but the omission should be rectified in any future editions.

The authors have aimed at including practically every organic arsenical compound reported in the literature up to date, they have consulted almost all the original articles and patents published in the English, German, French, and Russian languages, and there appears at the end of the volume a chapter on chemotherapy comprising 20 pages. The arrangement of the subject-matter in the body of the work is on correct lines, such as a chemist would expect. First there is a historical sketch of 17 pages; the trivalent aliphatic bodies with a little over 30 pages; then the pentavalent with a further 30, and then follow, systematically, unsaturated aliphatic arsenicals, and from page 103 onwards trivalent and pentavalent aromatic compounds, heterocyclic, miscellaneous compounds, and so on to the end.

In the historical sketch it is stated that the first recorded observations of the production of an organic arsenical compound, "Cadet's fuming arsenical liquid," were made in 1760 by L. C. Cadet de Gassicourt, a French military pharmacist working on an arsenical cobalt compound, with a view to making the best sympathetic ink. The events of 1914 and succeeding years make us wonder whether each of the participating nations proposes to keep its pet invisible ink a secret—we have seen nothing printed since the war on the matter. The American historical sketch proceeds almost exactly on the lines of Prof. Morgan's—excepting, of course, that the Englishman stopped in 1918, and, incidentally, has neatly arranged references at the bottom of each page. The subsequent work of Prof. Raiziss himself, Jacobs and Heidelberger, Fargher and Pyman, King, Wieland and Rheinheimer, and others are included in the American work.

Much of the work is of great value, and the result of learning, diligence, and research, but need we have had all that is given us? Let us take a critical example. It is known that manufacturers during the last few years found considerable difficulty in producing a body corresponding with the original neo-salvarsan, when proceeding according to the specifications in the German patent methods. On turning to page 195, we find an entire page devoted to seven different methods, or modifications of a parent method, by which to make novarsenobenzol. These are translations from Deutsche Reichspatente, Nos. 245756, 260235, 263460, 264014, and 271893. Knowing what a German specification has been in the past, and reading what the Medical Research Council recently had to say on the matter, the question was put specifically before a British firm with experience in the difficulty as to whether the methods given in this book would work. They replied (Feb. 11th, 1924): "... Though the directions could not be called purposely misleading, our works opinion is that not one of the directions, if followed closely, would give the desired product. One must regard these patent specifications as academic rather than practical, and as we have found it, the actual process of manufacture varies from every one of the patent specifications, and can only be arrived at by experiment and experience." Prof. Raiziss has himself worked on the compound, and has demonstrated the commercial drug to be a "non-uniform mixture of the mono- and di-N-methylenesulfinic acid derivatives of arsphenamin together with uncombined sodium formaldehydesulfoxylate, sodium sulfate and chloride." The page of erroneous patent specification directions might, therefore, have been omitted. We have counted the references to the D.R.P.'s on one page (p. 529) of the 15 pages devoted to the 1594 references. There are 22, in addition to three American and a few French and English. But a young and enthusiastic bench-worker who may think to hit on something novel may be disappointed, for search will probably show that all the *Ausgangsprodukte* are covered and hedged in by a network of patents, the mastery of which alone will cause him to wish he had the brain of a Bradshaw rather than of a Ramsay. There is, however, an advantage in having all these patent specifications collated in book form; they spur on the practical worker to find out how a compound is really made, and conversely how it cannot be made. Those who take out patents not seldom keep a "modicum" up their sleeves.

We congratulate Prof. Raiziss and his associate on their work in the chemotherapy chapter—and indeed on the entire book; but they do not countenance the most modern view of all, in criticism of Ehrlich's chemotherapy—viz., that a compound like salvarsan owes its activity to its organotropic rather than to its parasitotropic power.

MAN'S MENTAL EVOLUTION, PAST AND FUTURE.

By HARRY CAMPBELL, M.D., F.R.C.P. Lond. London: Baillière, Tindall and Cox. 1923. Pp. 74 + v. 3*s.* 6*d.*

THIS little book gives a survey of the mental progress of man from before the ape-stage to his present state as a social animal. Dr. Campbell follows MacDougall in regarding man's behaviour as essentially instinctive, and accepts Trotter's conception of the herd instinct; but he stresses the influence of intelligence, and decides that the more intelligent the person the more likely is his conception of right or wrong to conform to a code having for its standard the interest of others. This marks the distinction between Dr. Campbell and those who seek the explanation of certain a-social conduct in the influence of unconscious motives—a distinction of practical importance. He rejects the belief in any *élan vital* or "spiritual influx" by which the human race tends to advance intellectually or morally. Survival value is the thing that matters, and selection is still operative in man's moral evolution, so that he is probably becoming better adapted to the restrictions imposed by communal life. Dr. Campbell's thesis is clear and self-contained, but it may be doubted whether his premiss of individual moral evolution would be generally accepted. Morals are a matter of geography, goes the old saying; they are certainly a matter of history, and in overlooking social as opposed to individual evolution the author makes his task more easy but his results less convincing. The book would have been called "materialistic" a generation ago. It reminds us that there are established scientific theories with which modern psychology must be brought into accord.

EARLY TUBERCULOSIS IN ADULTS.

Die Klinik der Beginnenden Tuberkulose Erwachsener. By Dr. WILHELM NEUMANN, Privat Dozent at the University of Vienna. Vienna: Rikola Verlag. 1923. Pp. 158.

IN this monograph the author recounts the signs and symptoms of early tuberculosis in adults, and the means whereby early tuberculous changes can be detected. The subject is one with which every writer on tuberculosis attempts to grapple, and it is usually dealt with on conventional lines, inspection, percussion, auscultation, and the like, being described seriatim in a faithful and plodding manner. The author has, to a certain extent, digressed from this path; when he is conventional, he is helpful to the medical student and general practitioner, and when he is unconventional he has much to say that his fellow specialists will be interested in, and with some of which certain of them will disagree.

It is, perhaps, inevitable that the tuberculosis specialist should come to see signs of tuberculosis in almost every departure from the normal, just as alienists smell insanity in every eccentric trick and habit. Erythrism, or redness of the hair, is a case in point. The author distinguishes four different types of erythrism, and for almost every type the prognosis for tuberculosis is different. The red-blonde, whose hair is everywhere red, may suffer from latent or abortive tuberculosis, but never from phthisis running a malignant course. But such malignant phthisis is very common in the subjects of partial erythrism—i.e., persons with red hair on the pubes and face and in the axillæ, but not on the head. There are two varieties of this partial erythrism, according to the author, and the fourth main type is described by him as "hair disharmony," the possessor of, or sufferer from, which has a fuchsia-red moustache, but normal-coloured hair on his chin and pubes. This type is said to be prone to tuberculous peritonitis. Digressions on observations such as these stimulate research, but it is doubtful if many of them will stand the test of statistical investigations. The author deals almost as thoroughly with other parts of the body as with the hair. Differences in the colour of the iris on the two sides are referred to as degenerative stigmata which may or may not favour tuberculosis. The suggestion that there is more pigment in the iris on the side most affected by tuberculosis is well worth checking by the statistical method, and the value of this book would have been considerably enhanced if the author's correlations of various signs with tuberculosis had been supported by systematic comparative investigations.

BERGEY'S MANUAL OF DETERMINATIVE BACTERIOLOGY.

A Key for the Identification of Organisms of the Class *Schizomycetes*. Arranged by a Committee of the Society of American Bacteriologists: DAVID M. BERGEY (Chairman), FRANCIS C. HARRISON, ROBERT S. BREED, BERNARD W. HAMMER, FRANK M. HUNTOON. Baltimore: Williams and Wilkins Company. 1923. Pp. 442.

THIS is a work which cannot be adequately reviewed after mere perusal. It should be handled daily, in association with active work, before a weighed judgment as to its accuracy and usefulness can be arrived at. The prodigious and amazing energy, the breadth

of reading, and the tireless revision, which must have gone to its compilation, demand admiration for their mass alone. Everyone will admit that bacterial nomenclature is extremely unsatisfactory, and that in labelling such diverse forms as the organisms of the colon group, the spore-forming anaerobes, and the tuberculosis organism by the common name of bacillus we are reaching back to the very early and primitive days of the science. He who ventures to break fresh ground and propound an acceptable nomenclature is, however, venturing into a quaking bog. To the conservative British bacteriologist the book is at once a revelation and cause for distress. Gone are the time-honoured names and the traces of time-hallowed investigators which have always clung about them. *B. typhosus* (Eberth) finds no place in the index and has suffered transmogrification into *Eberthella typhi* (Eberth-Gaffky), Castellani and Chalmers. That reform and progress are both necessary and inevitable is a platitude, but we are not convinced that it is along the rigid lines laid down by our American colleagues that the most fruitful changes are to be made. In the end we shall probably be inconsistent, and whilst clinging to our old friends, such as the gonococcus, the tubercle bacillus, and *B. coli* (Escherichia coli), in other groups such as the spirochætes, we may adopt new suggestions.

It would greatly aid reference in this work if page-headings gave information as to the material dealt with instead of monotonously repeating the title of the book. An enormous number of species is included, some 850 odd being described, and we are dubious as to the advisability of lending countenance to the perpetuation, with specific rank, of saprophytic forms which have no commercial, pathological, or biological importance. Those who in the past have catalogued endless intestinal or other organisms upon such slender bases as sugar reactions, which probably are almost infinite in their possible combinations, have rendered an ill-service to bacteriology, and the the perpetuation of this kind of folly is quite undesirable. A short note upon the existence of such forms without detailed description would save much space for more important micro-organisms. The book contains no list of synonyms; no doubt these are intentionally excluded to enforce adherence to the nomenclature put forward. A valuable contribution to its subject, this work will doubtless find its way into all bacteriological laboratories; but it seems to prove the impossibility of its mission—the application of a binomial to the adequate designation of every known organism. Is the attempt worth it? We think not. Words are not so precious that so vast an amount of labour should be expended in bolstering up this botanical fetish.

PHARMACEUTICAL AND FOOD ANALYSIS.

A Manual of Standard Methods for the Analysis of Oils, Fats, and Waxes, and Substances in which they Exist; together with Allied Products. By AZOR THURSTON. London: Chapman and Hall, Ltd. 1923. Pp. 416. 21*s*.

THE title of this work is misleading, as it deals in general with the analyses of oils, fats, and waxes, as set out in the subtitle. Until the preface is read, there is no indication that the subtitle constitutes Part I., Part II., dealing with the analysis of the more common drugs and foods, being now in preparation. In future editions we would suggest that the division into Parts I. and II. should be made clearer or that other appropriate and distinctive subtitles be adopted. The first four chapters are concerned with polariscopes, refractometers, and the determination of specific gravity by various means, and general methods of analysis. Subsequent chapters are devoted to the commonly occurring oils, fats, and waxes, dairy products, flesh foods, eggs and egg substitutes, and the volatile oils. At the end of each section a bibliography up to date (1922) is attached, comprising the prominent American and English journals, all original articles appearing in these journals being included regardless of their importance. The absence of a name index is to be regretted.

Apart from these criticisms, the book is undoubtedly good, and it is a useful contribution to this important branch of chemistry. Indeed, this is to be expected from Mr. Thurston's long official association with American Food and Agricultural Departments. Not the least valuable portion is the list of adulterants based on the Federal notices of judgments, so far as these have a bearing on the subjects dealt with in this volume. It is obviously important that the analyst should know what adulterants are being used.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

X.—OBLIGATIONS TO HIS PATIENT.

BY JAMES NEAL, M.R.C.S. ENG.,
GENERAL SECRETARY OF THE MEDICAL DEFENCE UNION.

Aegroti salus suprema lex.

IT is the duty of a medical practitioner to place the interests of his patient above all other considerations, and to do his utmost to promote his patient's welfare. The British Medical Association has expressed the opinion "that a medical practitioner should not under any circumstances disclose voluntarily, without his patient's consent, information which he has obtained from that patient in the exercise of his professional duties." It may be said that this opinion is universally accepted.

Implied Warranty and Contract.

The fact that a medical practitioner is registered is an implied and public warranty on his part that he possesses the requisite ability and skill, and in every case that he attends he is legally bound to employ a reasonable amount of knowledge, skill, and care. In the absence of a definite arrangement that he shall not be paid, a medical practitioner is entitled (unless restrained by such a by-law as that of the Royal College of Physicians) to be reasonably remunerated for any professional services he may render. There is, however, nothing to prevent a medical man from attending a patient on the understanding that his services shall be gratuitous. It is commonly understood that a medical practitioner is at the beck and call of anyone who chooses to send for him. This is not the case. There is no law to compel a medical man to attend a patient, apart from any contractual obligation he may have accepted, but if he once undertakes to do so, he must not go back except at his own risk. Even if he is attending a case gratuitously, and wishes to withdraw from it, he should give the patient a reasonable opportunity of obtaining other medical assistance before he ceases attendance.

The relationship between a medical practitioner and his patient is one of contract, though usually the contract is only implied by the rendering of services by the medical practitioner for which he can claim to be reasonably remunerated. It is as well that the scale of such remuneration should be agreed with the patient at the outset, whenever possible, to avoid misunderstandings. It should never be forgotten that a medical practitioner has no right to do anything to a patient without his consent, or, in the case of a child, without the consent of the parents or guardians, save in emergencies when the medical practitioner must exercise his discretion. This applies not only to operations, but to mere examinations or any form of

treatment. When surgical operations are necessary, the ideal thing is to obtain the patient's consent in writing, and as the full extent of the operation frequently cannot be determined beforehand, it is well for the surgeon to get a written authority to exercise his discretion when the exact conditions are ascertained; but in practice this ideal can but seldom be attained. No surgeon can exceed the extent of his authority without some risk of laying himself open to a charge of assault.

Allegations of Negligence.

Everyone engaged in active practice, whether as general practitioner or as consultant, is liable in the ordinary course of his daily work to false charges, sometimes very serious, of professional negligence or incapacity. However well-informed a medical practitioner may be in his professional work, and however careful he may be in his treatment of a patient, he is always at the mercy of any person who may feel aggrieved. All that seems necessary from the patient's point of view as a foundation for an action for negligence or malpraxis is for him to conceive the idea that however serious his disease or injury may have been, he ought to have made a more rapid recovery or obtained a more perfect result. He bolsters up his claim with items for loss of wages, loss of health, nervous shock, expenses for visits to the seaside, massage, and the like, hoping that the practitioner will submit to his demands for compensation rather than face the ordeal of a public trial. No doubt it is a great temptation to settle a claim of this kind by a small monetary payment, and so avoid the publicity necessarily involved in court proceedings, but every case that is fought and won will help to protect other practitioners from having to face similar claims.

The majority of the allegations of negligence are set up as a counter-claim against the payment of professional fees. Fortunately, it is not sufficient for the plaintiff merely to contend that he has received no benefit from the treatment. If a practitioner has exercised due care and ordinary skill, he is entitled to be paid, although his treatment is unsuccessful. The mere employment of a medical practitioner does not imply a contract to perform a cure, but only that the medical practitioner will exercise reasonable care and skill, having regard to his position and standing in the profession.

But a patient is entitled to recover damages in respect of any injury caused through neglect or lack of skill on the part of his medical attendant, and it is a question for the jury in each case to say whether any injury is attributable to the want of a reasonable and proper degree of care and skill in the practitioner's treatment. If the jury finds that there was a lack of care and skill on the part of the medical practitioner, having regard to his status and experience, he will be held liable, but he will not be answerable merely because some other doctor might possibly have shown greater skill and knowledge.

In other words, a medical practitioner is not expected to show the highest possible skill, but he must have that amount of skill which should be possessed by a practitioner in his position. Accordingly, the degree of skill expected from a specialist will not be required from a country practitioner remote from teaching centres.

How to Meet Such Allegations.

A medical practitioner who is so unfortunate as to have his professional work called in question should make no reply to the allegation until he has been properly advised; it is impossible to emphasise too strongly the great protection which a practitioner derives in all such cases from membership of an experienced defence organisation. Too often when such cases come under notice, it is found that the position has been gravely prejudiced by injudicious letters which the practitioner has written without recognising their possible effect, and in too many instances without even keeping a copy. Errors in diagnosis are not necessarily due to negligence, and no guarantee is given or implied that a medical practitioner will diagnose correctly the ailment from which his patient is suffering. Questions of this kind frequently arise in connexion with the notification of infectious diseases, and it is seldom that an adverse verdict has been given.

Special care is necessary in dealing with cases of criminal wounding, as, if the patient should die, the person who caused the wounding may be charged with murder, and may set up the defence that but for negligence and unskilful treatment the original wound would not have been fatal. In all such cases the medical practitioner should be prepared to justify every step which he takes, and in grave cases should consult whenever possible with an experienced colleague. The most careful notes should be made in writing of the patient's condition when first seen, and his progress from day to day, with full particulars of all treatment afforded.

The introduction of X rays as an aid to diagnosis, and as a method of treatment, has given rise to many claims in respect of injuries received as a result of their use. Negligence may be alleged either with regard to the application of X rays, or even in not resorting to them. The desirability of requiring a patient to sign some form of acknowledgment of the risks attaching to the use of X rays, and his willingness to take such risks, has been frequently discussed, but no such acknowledgment would protect a practitioner from an action being brought against him for alleged negligence, and it might even be argued that its possession might have made him less careful than he otherwise would have been.

It must be remembered that a surgeon is held responsible for negligence on the part of those helping him at an operation. At such a time the surgeon is supreme, and assistants and nurses, although employed by a hospital at which the operation is being performed, cease for the time being to be servants of the hospital, and take their orders from the operating surgeon alone. The hospital does not as a rule incur responsibility, provided it has exercised due care in the selection of its medical and nursing staffs.

A Word about Gifts.

Owing to the peculiarly intimate relation of a medical practitioner to his patient, any business transaction between them must be fair and above-board, and it is essential that the patient be fully aware of what he is doing. There must be no possibility of a suspicion of undue influence on the part of the medical practitioner for his own benefit. This necessarily applies to any gifts from a patient to his doctor, and even to wills, whereby the medical attendant will benefit, except that in the latter case undue influence cannot be presumed, but must be proved, in order to invalidate the will. The influence which a medical practitioner necessarily and naturally possesses over his patient would not of itself be a ground for setting a will aside, unless it could be shown that the testator was coerced into doing what he did not really desire to do.

PRESENTATIONS TO MEDICAL MEN.—The retiral from practice of Dr. James Duffus, of Auchenblae, Kincardineshire, is fittingly commemorated in a public testimonial, subscribed by his many friends in the district which he served for 40 years. In addition to his professional duties, which won for him the highest esteem, Dr. Duffus has always taken an active part in the public, social, and recreative life of Kincardineshire.—A public presentation was made recently to Dr. W. C. Rigby of Adlington, Chorley, Lancs, from members of the local branch of the St. John Ambulance Brigade and other residents in recognition of his public services in Adlington and district. For some 28 years Dr. Rigby has been an enthusiastic supporter of the Ambulance Association, to which he devoted much of his leisure as instructor and examiner.

THE LANCET.

LONDON: SATURDAY, MARCH 8, 1924.

HARNETT v. BOND AND ADAM.

A SUMMARY is published in another column of the case in which Mr. W. S. HARNETT obtained heavy damages for detention as a lunatic while he was sane against Dr. C. H. BOND, Commissioner of the Board of Control, and Dr. G. H. ADAM, proprietor of the West Malling Private Mental Hospital. There is no doubt of the importance both to the public and the medical profession of the questions exposed in this case, and those who agree and those who disagree with the verdict alike will feel the need for new legislation which has long been overdue and which has been made the subject of definite ministerial promises. As we are informed that there will be an appeal from the verdict, and also that further legal action may be taken by the plaintiff, most of the particular aspects of the case cannot now be reviewed; but the evidence revealed in an unmistakable manner how serious is the responsibility which is laid upon our profession in regard to the certification of lunatics In a case where a jury has found that a terrible wrong has been suffered and that proportionate penalties (if possible) should be inflicted, it is right to express a double sympathy; and this can be done without prejudice to any subsequent proceedings. The paradoxical sentiment is the result of paradoxical law, which imposes upon medical men the duty of saying yes or no to questions that, in the present state of our knowledge, cannot always be met with such definite replies.

The verdict would clearly be wrong if convincing evidence had been forthcoming that the plaintiff was insane throughout his period of detention, but the jury came to a contrary decision with no difficulty whatever, being satisfied that many of the alleged symptoms of lunacy were capable of other interpretation, presumably whether considered separately or en masse; and therefore a large pecuniary compensation became immediately logical. In fact, no money compensation could meet the case. Accepting the definite finding of the jury that the plaintiff was not of unsound mind on the day when he was sent back into detention, and further, that he was not dangerous to himself or others but was fit to be at large, the question of whether those responsible for his detention believed that he was insane, and took all the necessary steps to ascertain that this belief was duly founded, presents to us two difficulties. The first is how the defendants, specialists though they might be, were to arrive at a definite decision of what makes a man a lunatic—that is a more definite decision than their judgment dictated; and the second is what procedure should they have adopted, other than that which they did as a matter of fact adopt, in answer to their convictions. In the evidence for the plaintiff an acknowledged authority was quoted as stating that there was no one who is absolutely sane, it being all a matter of degree. This is the position which influenced the actions of the defendants, and which makes it amazing and horrifying to medical men that the jury should have found that Dr. BOND was aware of the plaintiff's sanity at the time when he was taking measures to return him to confinement. We cannot follow this decision while it is widely admitted that there is no definite criterion of insanity. We have been unable to ascertain what steps can be taken legally to revoke a leave of absence granted to a certified man. This confession of ignorance of the law need not be concealed, when the learned judge has himself expressed surprise on learning that the certified lunatic is not personally made aware of the grounds of his detention. As this point has been made the subject of considerable comment, it ought to be quite clear that the information would not be withheld from the legal representative of the alleged lunatic, while the reticence as far as the certified person is concerned has its foundation in the hope that recovery may ensue. In such a happy event it might reintroduce into family life exactly the trouble which had been surmounted, if the person restored to his relatives should ascertain through whose instrumentality and on what grounds his segregation had been held medically necessary. A patient's continued detention rests not on the certificate, but on his mental state at a particular time.

Whether the judgment on appeal holds good or not, makes no difference to the fact that the lunacy laws must be amended. Medical men cannot face the risk under which, it seems, they lie at present, and for their protection, as well as for that of the public, the sooner these reforms are instituted the better. And within the medical profession the need for schools of psychiatry will now be recognised more fully. Three years ago, at an important meeting of the Medico-Psychological Association, Dr. BOND outlined the necessity that clinics should be held in mental disease in affiliation with general hospitals. He pointed out the relation which such clinics would occupy with regard to other clinical units, and laid stress upon the advantages to the medical profession of acquiring greater skill in the differential diagnosis of mental disorder. This reform, which has been advocated steadily in these columns, would obviate many of the difficulties with which lunacy certification is surrounded. But far more is required; and we welcome the decision of the Prime Minister that, prima facie, there is a case for full inquiry. This inquiry will probably follow immediately upon the result of any appeal, and, we imagine, will lead to vital alterations in the law.

ON WASHING AND ASEPSIS.

IT is one of the earliest recollections of our boyhood that we regarded washing as an effeminate superstition, and now, after many years, we find our instincts vindicated and our views upheld by no less a person than the Assistant Master of the Rotunda. In the important and suggestive article on surgical asepsis which we print on another page Dr. G. W. THEOBALD and Dr. J. W. BIGGER produce strong evidence that prolonged washing, far from sterilising the hands, serves only to bring up more bacteria to the surface, and if, as is usually the case, the hands be then inserted into wet gloves, an emulsion is formed, swarming with organisms ready to escape at the smallest puncture. They would insert "socially" clean hands into dry unsterilised gloves, which they wash and immerse in an antiseptic solution, and they hold that the result is entirely satisfactory. Now, there can be no doubt of the folly of imagining that the hands can be sterilised by washing, however prolonged, and indeed, unless elaborate precautions are taken the practice may be absolutely dangerous. We have known of more than

one case where a severe dermatitis was produced by scrubbing the hands with an infected nailbrush. The smooth surface of a rubber glove lends itself much more readily to mechanical cleansing, whilst it is not injured by the action of antiseptics which would ruin the skin. For the performance of dressings, or minor surgical procedures, and of those complicated obstetric manœuvres where perfect asepsis is a practical impossibility, there can be no doubt that the method suggested is admirable and far superior in actual results to the more complex methods in general use. Moreover, it is so simple that it can be carried out by individuals and under circumstances where the ordinary routine would certainly fail.

There are, however, certain criticisms which we feel bound to offer to the method proposed, since they seriously affect its value for the work of the general surgeon. It is an essential part of the method that some reliance is placed on antiseptics, and in particular on 1/1000 biniodide of mercury. Now, recent work has shown that, in general, mercurial solutions merely prevent growth and do not destroy bacteria. If the mercury is precipitated by means of hyposulphite of soda the organisms will in many cases be found to grow with undiminished vigour. Observers have seen thin fragments of infected tissue incubated in 1/500 biniodide for three months, and at the end of that period a few grains of hypo produced a rejuvenescence as startling as that attributed to salt taken in the morning tea. But no such precaution appears to have been taken in the tests described, and we must for the present feel a certain hesitation in accepting, sine grano salis, the statement made that gloves infected with virulent pus can be sterilised by mechanical washing and the use of dilute antiseptics. In the doctrine of abstention our authors are on much safer ground, and we should have liked to see them carry it somewhat further. The most perfect practitioner of the art we have ever heard of refused to shake hands except in gloves, or to button his own boots, and he never touched coins with bare hands. Needless to say, he had no sense of humour, but his surgical asepsis was perfect. Without going quite so far it would be well that every student should be taught how much easier it is to avoid infection than to remove it. In the ideal clinic no piece of dressing, clean or infected, should ever be touched by the hands, gloved or ungloved, but only by forceps which have just been boiled. Were such a regime rigidly enforced the transference of organisms from one patient to another would become virtually impossible, and this after all is the practical meaning of surgical asepsis.

It is the prevention of transference, with its inevitable corollary of the development of bacteria of exalted virulence, that is the foundation of modern surgery and obstetrics. In the old days surgeons were not even "socially" clean, and wore, we are told, frock coats stiff with the blood of years of practice. We have long got rid of such gross and open sepsis, but it still behoves us to be on our guard. It would be well if surgeons, dressers, and nurses would bind themselves, under a solemn vow, never to touch a dressing with aught but forceps, never to touch infection with a hand ungloved, and never to put a hand where an instrument would do as well. In many a ward asepsis would be enormously improved if washing between dressings were strictly forbidden. Yet there is moderation in all things, and perhaps the dangers even of washing can be exaggerated. It is only over the doors of the laboratories of a certain branch of science that its more advanced votaries have inscribed the motto, "All soap abandon ye who enter here."

THE INVESTIGATION INTO FOOT-AND-MOUTH DISEASE.

THE loss to the agricultural interests of this country caused by the epizoötic of foot-and-mouth disease, now fortunately abating, may be partly realised from the statement that the estimated gross sum involved in compensation amounts already to over £2,900,000. This, moreover, is no true measure of the disaster from the point of view of the farmer deprived of valuable pedigree or dairy stock, and suffering from interrupted farm and dairy business; nor does it take account of the injury to farm hands who have lost employment or of the inconvenience to the general public. The enormous importance to the country of acquiring control of this disease, and the devastating effect of want of knowledge concerning some of its essential features, have now been widely realised by all classes of the community. The actual presence of the scourge has forced all concerned to recognise the need for a thorough inquiry; while at the same time it has counteracted the timidity which shrank from facing the really small but often greatly exaggerated risks involved in conducting experiments with the virus. The personnel of the committee appointed to conduct an inquiry and to initiate and direct research has been announced (see p. 521), and it is to be hoped that before the country has thoroughly recovered from the epidemic the institution of well-planned research will have been faced and accepted, and its safety recognised. We sincerely trust that this time vows uttered in distress will not be put aside when the period of immediate danger is over. It is indeed remarkable that with so serious a calamity as an extensive epizoötic of foot-and-mouth disease hanging continually over the country so little demand for persistent research should have been made.

There is still great uncertainty about many of the important factors producing both initial outbreaks and subsequent extensions of foot-and-mouth disease. The highest authorities express divergent views on such fundamental matters as the possibility that fodder or litter from abroad, even from South America, could carry the infection to this country. Again, in spite of diligent inquiries and a great desire to learn the truth, we are almost entirely ignorant as to how it happens that outbreaks occur in unexpected places, sometimes 50 or 100 miles from the nearest antecedent infected area. An instance is the recent outbreak in Scotland which, according to Sir STEWART STOCKMAN, is only the second such occurrence north of the Border in the last 22 years. No better explanation is forthcoming than the possible transmission by an untraced human being, by birds, or by vegetables from the continent, the source of infection in any case being purely suppositional. It is not so much the unexpected appearance of cases of disease which causes surprise as the absence of definite knowledge whether it is even possible for any of the suggested means of transference to be effective. One reason for our ignorance as to the means of transmission may be the uncertain infectivity of material from diseased animals. Saliva and the contents of vesicles sometimes contain extremely concentrated virus; in other cases these materials appear to be inert. This variation may be strictly dependent on the stage of the disease, as Vallée has suggested, but in any case no "virus" from affected animals, however probable its activity may appear, can be assumed to be virulent without being tested.

Whilst much of the evidence adduced is necessarily inconclusive and circumstantial, the accounts by veterinarians of epizoötics of foot-and-mouth disease, and the means taken to combat them in different countries, contribute suggestive data for further scientific inquiry. In the current number of the *Veterinary Journal* much information of this kind has been collected, together with a brief survey of the present epizoötic. The method of dealing with outbreaks, and the results obtained in Switzerland, by

Prof. M. L. PANISSET, are of special interest on account of the thoroughness of the regulations and the care with which they appear to have been carried out. A stricken farm was surrounded with barbed wire, all ingress or egress of man or animals was forbidden, and small animals such as fowls, cats, and rabbits were destroyed. Nevertheless, though these efforts had a certain effect early in the epizoötic, we are told the spread of disease was not prevented. If, as the small amount of published experimental work suggests, inanimate objects can only retain the virus in an active state for a very short time, then the possible transmission by actually infected birds, rats, mice, rabbits, cats, and the like, becomes a more important subject for inquiry. Some most interesting experiments bearing on this question were published by Prof. J. M. BEATTIE and Mr. D. PEDEN in THE LANCET of Feb. 2nd. These writers are inclined to believe that they infected rats with foot-and-mouth disease by feeding them on the lymphatic glands of diseased cattle. The rats showed vesicles on the tongue and feet, and other rats were infected from them. The disease produced had a striking resemblance to experimental foot-and-mouth disease in the guinea-pig. Unfortunately they were hampered by want of a further supply of virus, and by lack of opportunity to determine by experiments on cattle or sheep whether the infected rats really suffered from foot-and-mouth disease or not.

No statement has yet been published as to the conditions under which research will be conducted through the newly-appointed committee. On those dealing with so complex a task no unnecessary restriction should be imposed. Fortunately it is possible to infect guinea-pigs and to carry on the disease by passage in these animals alone, but it is necessary at times to confirm the diagnosis of the disease in rodents by testing the virus on susceptible ungulates, and space will be needed for keeping and isolating a number of large animals of the kinds most susceptible to the disease. Researches on birds and small mammals can, no doubt, be carried out without risk in properly equipped laboratories, and it is hoped facilities for obtaining virus for this purpose will be given to responsible pathologists who are well qualified and well situated for the conduct of such intricate work. If an experimental farm were established, virus could be given to recognised pathologists, and material of real importance could be tested on large animals; then work similar to that of BEATTIE and PEDEN would be encouraged and brought to fruition. The accommodation necessary for large farm animals would be considerable, and it would be important to avoid clogging the wheels of research by making demands for unnecessary tests. For the purpose of coördinating the associated activities of pathologists in different places the committee will, no doubt, prove efficient. One of the most important and by no means easy duties of an experimental station is the maintenance of a supply of virus. This must be provided for by passage in animals, and also by preservation of a stock of virus in cold storage. The question of "carriers" amongst recovered animals which harbour and distribute the virus, especially in connexion with deep infections of the hoof, is another point to be investigated.

While the natural means of transmission and the measures available to frustrate them are of great importance, especially in this country, the intimate nature of the virus and its possible cultivation in artificial media must not be neglected. The hope implied in this latter inquiry is that means of producing a more certain and lasting immunity than can be obtained by any known method may be discovered. The whole question of immunisation by serum or blood, and the questions of vaccine and serum therapy, are still far from being satisfactorily settled, and it is possible that the efforts of a committee appointed to investigate this one affliction may result in clearing up fundamental points common to many diseases.

Annotations.

"Ne quid nimis."

THE DANGER OF FROZEN SCHICK SERUM.

WE have received through the Registrar of the General Medical Council a copy of the following despatch from H.M. Consul-General at Boston, U.S.A.:—

SIR,—I am not aware whether the discovery, announced in to-day's local Boston press, that Schick serum becomes poisonous when frozen, is generally known in medical circles at home, or how far the use of this serum for inoculation against certain diseases is practised in the United Kingdom. It therefore appears advisable to report the alleged discovery which is stated to have arisen from the poisoning of 19 students at Concord Academy. Freezing, it is stated, destroys the antitoxin in the serum, and leaves nothing but the poison to be administered. It is expected that the effects of the poisoning will only last about two weeks, the patients being kept in darkened rooms for three weeks as a precaution. It is announced that the entire shipment of the serum used is to be destroyed.

British Consulate General, Boston, Feb. 7th, 1924.

This occurrence received notice in the *Journal* of the American Medical Association for Feb. 16th, when the number of affected institutions was given as two and the number of students affected as 44. At the request of the Massachusetts State Commissioner an investigation was made into the circumstances by Dr. W. T. Harrison, of the U.S. Public Health Service, with the help of Dr. Bela Schick, Dr. W. H. Park, Prof. M. J. Rosenau, Dr. Hans Zinsser, and Dr. E. H. Place. It appeared that certain phials of two lots of diphtheria toxin-antitoxin mixture which had passed all the usual tests were exposed after distribution during the recent extremely cold weather to temperatures of 0° F. or lower. Hundreds of other phials of the same lot numbers, not exposed to low temperatures, were used in other cases and produced no unusual reaction. Laboratory experiment showed that while a short period of freezing did not materially affect the toxin-antitoxin mixture, severe freezing for 18 hours apparently caused the antitoxin to dissociate from its combination with the toxin and to assume a changed physical state. The experts consulted viewed the occurrence in the light of a discovery of which note should be taken, but which should in no wise discourage the use of toxin-antitoxin mixtures for protection against diphtheria. The results of the injection of serum which had been frozen could not have been foreseen and no blame was attached to anyone in connexion therewith. The Massachusetts Commissioner added that his confidence in the value of the serum was in no way altered and that experiences such as this, distressing as they must be, should not cause health officers to abandon the use of a valuable preventive measure. At the time of the report all the patients were recovering.

RADIOTHERAPY FOR SARCOMA.

THE Radium Institute in Paris has issued in *Paris Médical* for Feb. 2nd a report, signed by MM. C. Regaud, J. Roux-Berger, J. Jolly, A. Lacassagne, H. Coutard, O. Monod, and G. Richard, on the treatment of sarcoma with the X rays and radium. The chief lesson of this paper is that the term sarcoma covers a very mixed collection of new growths, whose origin, structure, degree of malignancy, clinical evolution, and response to radiotherapy vary so greatly that the first need is for a more accurate classification of this group of growths. But of its malignancy and refractoriness to treatment in most cases there can be no doubt. Of the 62 patients treated at the Radium Institute in the years 1919, 1920, 1921, only 16 were still alive at the beginning of 1923, and the permanency of the recovery in these 16 cases could certainly not be guaranteed. Of the 25 patients suffering from lymphoid sarcoma, eight were treated with the X rays alone, five with radium alone, and ten with the two

methods combined. There were also two patients who were given combined radiotherapy supplemented by operative interference. Early in 1923 six of the patients in this group were still alive, and of the 19 patients who had died, nine had been rid of their primary lesions, and several had for more than a year enjoyed apparent recovery. Of the remaining ten patients none had achieved local recovery, although some diminution of the primary growth had taken place, and in almost every case there had been appreciable amelioration. It would seem that radium is to be preferred to X ray treatment only in exceptional cases, and that X ray treatment is capable of achieving local recovery in most cases of lymphoma and myeloma. The metastases, which are so very common, presumably start before the successful treatment of the primary lesion is instituted, and this fact is the chief stumbling-block to both radiotherapy and operative treatment. There is another difficulty connected with radiotherapy in sarcoma. Some sarcomas are much more radio-sensitive than others, and were it possible without injury to the patient to make an exploratory excision and identify the histological characteristics of the new growth, radiotherapy could be reserved exclusively for cases which were radio-sensitive. In the absence of a preliminary microscopic examination, radiotherapy is rather empirical, and an exact opinion on the nature of the growth cannot well be formed till its reaction to this treatment is observed. While operative treatment is usually ineffective and often disastrous in cases of lymphoma and myeloma (unless a myeloma of a limb can be removed by amputation) X ray treatment is justifiable in such cases. But operative treatment is to be preferred in cases of fibroplastic sarcoma, because this is usually very radio-resistant.

THE PHYSICIANS' LIBRARY OF PHILADELPHIA.

THE Library of the College of Physicians of Philadelphia enjoys an endowment consisting of some 28 separate "funds" for the purchase of works of especial interest, and the Fund for Rare and Valuable Books has enabled it during 1923 to add to an already incomparable collection of incunabula. "These fifteenth century books," says the learned librarian, Mr. Charles Perry Fisher, "have been acquired for the library without in any way interfering with the purchase of current medical publications." The Philadelphia librarian and his committee have thrown their net widely, and have now included in their list a number of works not strictly medical, such as those of Boethius, the Epigrams of Ansonius, the "Noctes Atticae" of Aulus Gellius, the works of the Christian Father Lactantius, and of others, who were rather doctors of theology than of medicine. We note the very rare first edition, printed in Paris in 1517, of the "Tractatus insignis et exquisitissimus de superstitionibus contra maleficia seu sortilegia que hodie vigent in orbe terrarum," by Martinus de Arles y Andosilla. Two old French works on the care of the teeth and on the medical education of children are of interest considering that they were published at a time when these subjects—by us considered so recent—attracted no particular attention. These are Bourdet's "Soins faciles pour la properté de la bouche, et pour la conservation des dents," published by Mourer at Lausanne in 1782, and Brouzet's "Essai sur l'éducation médicinale des enfans," two volumes, published by Cavelier in Paris as early as 1754. A very interesting English work—considering its early ante-Harveian date—is Walter Charleton's "Three anatomic lectures; concerning the motion of the blood through the veins and arteries; the organic structure of the heart; the efficient causes of the heart pulsation." This was published in London by Kettilby in 1583, when William Harvey was five years old. Non-malignant tumours were in the past constantly mistaken for true cancer, whence such a work as Edward Guy's "Practical Observations on Cancers and Disorders of the Breast, explaining their different appearances and events. To which are added one hundred cases, successfully treated without cutting," London, 1762. The plague was long believed to be contagious; hence Sir Arthur Brooke Faulkner's "Treatise on the Plague, designed to prove it contagious, from facts, collected during the author's residence in Malta . . . in 1813." One work on "anthropology" figures in this fascinating library report. The term was anciently used to mean a description of a man, rather than of man at large, but even so we question whether we can rank under this heading the "Anthropologia" of Magirus (published at Frankfort, 1603), "hoc est, Commentarius . . . . Philipp. Melancthonis libellum de Anima." We take it that the book is not a commentary by Magirus on Melancthon's work, but that both rank as anthropology in the ancient sense. "Anima" as used by Melancthon is a theological term, and does not refer to physical breath. All in all, this great medical library now contains over 140,000 volumes and represents worthily a great tradition.

A NEW METHOD OF RATIONING ARTIFICIALLY-FED INFANTS.

ARTIFICIAL feeding for infants is rapidly becoming an exact science, and the margin of error due to the personal equation is yearly being reduced. The latest advance in this direction has been made by a Danish physician, Dr. H. Trepka Bloch, who has recently published [1] an account of a new method of rationing artificial meals for infants. The method, which is ingenious and carefully thought out, is particularly well adapted for the use of unskilled persons—indeed, it might almost be described as fool-proof. Briefly, it consists in the use of a gauge-glass, 8 inches high (here shown rather less than half-scale [2]), shaped like an ordinary urinometer, on which are engraved two scales, one for milk and the other for water. The divisions on the scales indicate the quantities required for each feed in the 24 hours by a baby of average weight for every week of its age, up to six months in the case of milk and five months in the case of water. The milk is poured into the gauge-glass up to the line on the milk scale which indicates the age of the infant. Water is then poured into the milk up to the line on the water scale on which the same age is indicated. The infant is thus at any given time receiving the exact dilution appropriate to its age, until it is six months old, when it should be taking undiluted milk.

The graduations of the gauge-glass have been calculated on the basis of the curve of weight of artificially reared infants published by Camerer, and are such as to secure that an infant of average weight for its age receives in the 24 hours 100 calories per kilo. of body-weight—this number representing what the consensus of expert opinion has laid down as the optimum requirement of an infant. While the scale is arranged for infants of average weight—that is, for babies weighing between 3 and 3½ kilos. (between 6½ and 7½ lb.) at birth, infants of more than average weight may be given the larger quantities and stronger dilutions calculated for half or one month ahead of their age; and, conversely, a small or marasmic baby may with equal facility be given correspondingly reduced mixtures. Indeed, in many cases the age need not be taken into account at all, since Dr. Bloch has supplied a table showing the calorie value, with a given number of meals, of the 24 hours' ration, with each graduation of the gauge-glass, and all that will be necessary will be to

[1] Særtryk af Ugeskrift for Læger, 1923, Side 124.
[2] The gauge-glass is manufactured by Messrs. H. J. Elliott, 20, Cross-street, Hatton-garden, from whom particulars may be obtained.

Table of Milk Mixtures Determined by the Gauge-Glass.

End of—	Ratio of milk to water.	Each feed: milk water.	Number of meals.	Quantity in 24 hours.	Calorie value of each feed (milk).	Calorie value in 24 hours (milk + sugar).	Weight curve of artificially reared infants (Camerer).
0 week	1-2	10 +20	8	240	6·5	71	about 3300
1 ,,	2-3	20 +30	8	400	13·0	136	—

6 month / 26 week	Undiluted milk.	200 0	5	1000	130·0	730	7278

weigh the infant and to begin the feeding at the line on the gauge-glass corresponding to the number of calories needed for that particular weight.

In the following table 100 g. of milk are assumed to yield 65 calories, corresponding to 3·7 per cent. of fat. Even where the percentage of fat is increased or reduced by 0·5 per cent., the difference will only amount to six or seven calories per kilo.—an error which may quite well be regarded as negligible. The quantity of sugar to be added to the feeds is given as 2 per cent. (two level teaspoonfuls) for each half-litre of milk and barley-water—a proportion used in Denmark for many years—which will approximate to the 7 per cent. of sugar in human milk. 100 g. of sugar are assumed to yield 410 calories, 2 per cent. of sugar giving about 80 calories per litre.

It will of course be self-evident that the quantity given at each feeding will depend upon the number of feeds given in the 24 hours, and that if six to five meals at three- to four-hourly intervals be given, as is usual in this country, each individual feed will have to be considerably in excess of the quantities allowed if the same degree of dilution be maintained. It is here that the only practical difficulty in the application of Dr. Bloch's method, at least by unskilled persons, is likely to be met with. In all other respects the scheme appears to have been devised upon thoroughly scientific lines, the aim having been throughout to systematise the artificial feeding of infants in such a way as to eliminate some of the grosser elements of danger, such as those connected with over-feeding and with a sudden transition to stronger dilutions.

THE TUBERCULOSIS NURSE.

THE lot of the tuberculosis or sanatorium nurse has hitherto been hard, and it is to be hoped that the steps recently taken by the Society of Superintendents of Tuberculosis Institutions will secure her better conditions. At present she has, as a sanatorium nurse, no official status; she may have worked for years in a sanatorium under a fully-trained sister, but if the nurse wishes to take up work in a general hospital she must start from the bottom rung, going again through that disciplinary moulding which, however salutary, is not a process the average woman would care to repeat. This is one reason why it is difficult to obtain a good class of probationer in sanatoriums. Another reason is the comparative monotony of sanatorium work. It would be easier to endure if there were a prospect of some official recognition which would give the experienced sanatorium nurse a generally accepted status. Without such official recognition things are bound to go from bad to worse, only ex-patients or women not acceptable to the general hospitals undertaking the nursing in sanatoriums. Matters could hardly be otherwise; sanatorium routine is dull, lacking the vestments, ritual, and aromas which make a sensuous appeal in the operating theatre as elsewhere. The atmosphere of the sanatorium, barren in more than the physical sense, may fail to keep alive interest in its work. These are some of the considerations which have led the Society of Superintendents of Tuberculosis Institutions to formulate a scheme for the training, examining, and certificating of tuberculosis nurses who fulfil certain requirements. Before a certificate is granted, the nurse must have undergone a period of training for two years, or, if she is on the general register of the General Nursing Council, for one year. She must give evidence of special knowledge of tuberculosis as well as general knowledge of nursing, and she must have mastered the elements of anatomy, physiology, and hygiene according to the syllabus of the General Nursing Council. The examination for the Society's certificate will be held in May and November of each year under conditions calculated to make the test severe and the passing of it a guarantee of efficiency. Undoubtedly, every effort will be made by the Society of Superintendents to keep at a high level the standard of their proposed examination, particulars of which will be found in the February number of *Tubercle*. But the fate and value of the proposed certificate will to a certain extent depend on the attitude adopted towards it by influential bodies in the nursing world, and it is to be hoped that, unless they can produce a better scheme, they will help forward a movement intended for the benefit of a hitherto neglected branch of nursing.

THE RESISTANCE OF INSULIN TO HEAT.

REPORTS have come home from India from time to time suggesting that insulin loses its properties when it is kept in a hot climate. This matter formed the subject of a joint letter from two British firms of manufacturing chemists (THE LANCET, Jan. 12th, 1924). In this it was shown that insulin was unaltered by its exposure to the climate of India, and suggested that the erroneous impression was due to the nature of the rabbit which was used to test the strength of the insulin. The *Indian Medical Gazette* for January, 1924, has just reached us, and sets out the evidence on which the statement was made that the insulin had lost its properties. Major J. Taylor and Dr. A. R. J. Douglas first gave the insulin to a patient who had a very high blood-sugar. The dose of insulin varied from 10 to 25 units, and the fall in the blood-sugar was insignificant; but since carbohydrate had been given at the same time it is not surprising that the blood-sugar did not fall much. As the experiments on man seemed unsatisfactory the insulin was tested out on rabbits. Although 50 units were given to a starved rabbit, the blood-sugar did not fall and the animal was quite unaffected, whereas 3 units will send a rabbit into convulsions in England. On this animal evidence it seemed certain that the insulin had lost its potency. But when the British Drug Houses tested insulin which had travelled to and from India it was found that even the insulin in a half-used bottle was still just as potent as it had been when it was first put up. It was therefore suggested that the Indian rabbit was at fault in its response to insulin and that the insulin was unaltered in the hot climate. An editorial note is added to Taylor and Douglas's paper, pointing out that at least one good clinical

report had already been published in India with European insulin. It seems clear therefore that the fear that insulin may deteriorate in hot climates is unfounded, that the error arose partly from the fact that an unsuitable patient was first tested, but mainly because the rabbit in India behaves differently from the rabbit in England. Diabetics who intend travelling to India and other hot climates may rest assured that the insulin will retain its virtues.

THE POPULATION OF SCOTLAND.

THE former volume embodying the result of the thirteenth census enumeration in Scotland was preliminary, giving simply the population figures of the more important administrative divisions of the country. The present volume [1] gives detailed information for these divisions respecting ages of the population, conjugal condition of persons aged 15 and over, orphanhood, birthplaces of the population, Gaelic-speaking population, and housing conditions. The total population of Scotland now approaches 5 millions; its actual increase between 1911 and 1921, owing largely to war conditions, having been only 2·6 per cent., as compared with 6·5 per cent. in the previous decade. Another reason for the lowered rate of increase is the decline of the birth-rate, and this is illustrated also by the increasing average age of the population, which for both sexes was 28·0 in 1911, and had become 29·6 years in 1921. Five full-page charts of age-distribution of the population in 1921 and 1911 show the effect of the war in diminishing the proportion of males aged 20–40 as compared with females and as compared with males at the earlier period. The statistics of orphanhood of all children under 15 have much interest in view of the likelihood of widows' pensions in a not very distant future. Of the nearly 1½ million children under 15 in Scotland in 1921, 88·8 per cent. had both parents alive, the fathers of 7·2 per cent. were dead, and the mothers of 3·2 per cent. were dead, while 0·8 per cent. had both parents dead. The housing statistics are of great importance from a public health standpoint, and we must express our regret that the systems of tabulation of this important section of census results in the English and the Scottish reports are not completely identical, with the result that the path of the social inquirer desiring to make comparisons is rendered unnecessarily difficult.

THE OXFORD UNIVERSITY PRESS.

THE Directors of the Oxford University Press celebrated with an important luncheon party, on Shrove Tuesday, the removal of their London head-quarters to Warwick-square, where the new buildings will be known as Amen House, in reminder of their previous location at Amen Corner. The Oxford University Press has been in existence for some 250 years, its first duty being to supply to the public bibles and prayer-books. This business was first transacted from the University, but late in the eighteenth century a warehouse was opened in Paternoster Row, and the trade was conducted from that centre in the City for a hundred years, at which period—namely, about 1870—the University Press began to take its place in the general publishing trade. At this time Dean Kitchin and Dr. Bartholomew Price, the Master of Pembroke College, Oxford, were in succession secretaries to the University Delegates, the authorities of the Press, and Mr. Henry Frowde was manager of the Bible Warehouse. Kitchin introduced the Clarendon Press books, edited by himself and famous scholars like Skeat and Aldis Wright, and the secular publications, which for a few years had been published for the University by Messrs. Macmillan, were now taken over under Frowde's management. No one needs to be reminded of the high place which the Oxford University Press was now taking in the publishing world at home and abroad, and under the direction of the present publisher, Mr. Humphrey Milford, these activities have been extended in many directions, so that the general catalogue of the Press now contains a description of some 10,000 books, a total which is daily increased.

At the luncheon to celebrate the opening of the new buildings the Chancellor of the University of Oxford, Lord Curzon, presided, and was supported by the Archbishop of Canterbury, Lord Balfour, Mr. Asquith, the Bishop of London, the Bishop of Ripon, and the Vice-Chancellors of Oxford, Cambridge and London, while the guests numbered the heads of the great publishing houses and many leading persons in the literary and scientific world. The speeches were from different aspects fully informative of the great work which has been done by the Oxford University Press throughout its long existence. The Archbishop of Canterbury pointed out that apart from moral influence exercised by the wide publication of the Scriptures, scholars owed a great debt to the University Press for the publication of works that could not in themselves ever be remunerative, while Mr. Asquith, in a serious but cajoling speech, described the successful efforts of the Press as a development of a system of pooling, under which the publication of popular classics, and even of children's books, provided the funds to defray the issue of large works with less public appeal. Lord Curzon, in replying for the Press, was very happy in his humorous presentation of the merits of the University of Oxford over the University of Cambridge, while he signalled out for particular mention as the result of the work of the Oxford Press the new Oxford Dictionary of the English Language, the new edition of Liddell and Scott's Greek Lexicon, and the continuation of the Dictionary of National Biography. He thought that the Archbishop laid undue stress upon the publication of unremunerative or erudite work, and assured Mr. Asquith that the Press would publish lyrics by himself, a romance by the Archbishop, or a detective novel by Lord Balfour. He joined with the proposers of the toast to which he was replying in testimony of the excellent printing and format of the productions of the Press, and to the admirable work done by Mr. Humphrey Milford, the University publisher, and his colleagues. He concluded his speech by proposing the health of Lord Balfour as the ideal Chancellor of the "second ideal university," a challenge which Lord Balfour accepted very happily, by pointing out that the new edition of Liddell and Scott must pay its debt to such Cambridge scholars as Richard Jebb, and that the issue by the Cambridge University Press of famous English poets had provided the best material for the Oxford Dictionary of the English Language.

THE MEDICAL AND DENTAL REGISTERS.

THE Medical and Dental Registers for 1924 reach us on March 4th. The number of names added to the Medical Register during the year 1923 was 2482—far the highest number on record—distributed as follows: England, 975; Scotland, 878; Ireland, 385; Colonial, 238; and Foreign, 6. During the same period 105 names were restored to the Register and 923 names removed; 648 on evidence of death, 1 on ceasing to practise, 270 on non-response to inquiries, and 4 by direction of the Council. The total number of names on the Medical Register on Dec. 31st, 1923, was 48,140. The additional names account for the increased number of pages in the Register itself, the only substantial addition to the preface being the text of the Dentists Act of 1923. The Warning Notice has been shortened by omission of a section dealing specially with dentists, which has now been transferred to the Dentists Register. The Dentists Register contains 13,473 names, being 711 more than last year. During 1923, 1488 names

[1] Census of Scotland, 1921. Report on the Thirteenth Decennial Census of Scotland. Vol. II. H.M. Stationery Office, Edinburgh. 20*s*. 9*d*.

were added by registration and, of these, 614 were registered with British qualifications, and 867 registered under the Dentists Act, 1921. Colonial registrations numbered 6 and Foreign 1. During the same period 484 names were restored to the Register and 1261 removed: 207 on evidence of death, 1 on ceasing to practise, 794 on failure to renew the annual certificate, 255 on non-response to inquiries, and 4 by direction of the Council. Contrary to expectation, the total number of names on the Dentists Register has been far more than kept up. In response to a request from many quarters for a list of dentists practising in various localities, the Dental Board has in preparation a list showing under each town the names of the dentists practising therein. For this year the list will be published separately from the Register at 3*s*. 3*d*., post free. Enclosed in the Dental Register is a pamphlet containing the names of dental companies—that is to say, of bodies corporate carrying on the business of dentistry on Jan. 1st, 1924. At the same time the usual list reaches us of medical and dental students registered during the year 1923, the total number so registered being 545 medical and 107 dental. The figures in each case are for their smallness without parallel since 1888, and in the case of medical students without parallel at all, being less than a third of last year's entry.

The Provisional Committee of the American Hospital in London is now ready to receive patients at their temporary headquarters, Manor House, 47, St. John's Wood Park, N.W. 8, near Marlborough-road Station. The patients are limited to American citizens, American wives of British subjects and their children. Applications for the admission of patients, and all communications relative to the hospital, should be directed to Mr. Philip Franklin, F.R.C.S., Medical Director, 27, Wimpole-street, London, W. 1. (Telephone: Mayfair 868.)

THE following lectures will be delivered at the Royal College of Physicians of London, Pall Mall East, during March and April, at 5 P.M. Lt.-Col. Glen Liston will deliver the Milroy Lectures on March 11th, 13th, 18th on the Plague. The Goulstonian Lectures will be given by Dr. Leonard G. Parsons on March 25th and 27th, and April 1st on some Wasting Disorders of Early Infancy, while the Clinical Features of Foreign Bodies in the Bronchi will be dealt with by Dr. Thomas McCrae in three Lumleian Lectures on April 3rd, 8th, 10th.
